The council of the Guild of St. Luke, SS. Cosmas and Damian, at a meeting on June 7, decided that the Guild should resume activities, and arrangements are being made for meetings of all branches to be held in the forthcoming session. Publication of the Guild's *Journal* is also to be resumed at the earliest opportunity. Subscriptions will become due when the new session opens, and application will be made for them by the Treasurer.

The Central Co-operative Anti-Malaria Society, Ltd., celebrated in December, 1944, the 25th year of its existence, under the presidency of Mr. L. K. Elmhirst, Agricultural Adviser to the Government of Bengal. In a special message to the society Mr. R. G. Casey, the Governor of Bengal, said: "By mobilizing popular support in the fight against malaria, and by stimulating interest in preventive measures, you are undertaking a task which is in accordance with the highest ideals of public service, and I wish you every success in your future efforts."

Mr. Basil Hughes, F.R.C.S., has resigned his position of honorary surgeon to the Bradford Royal Infirmary and to St. Luke's Municipal Hospital, Bradford, on his retirement from practice. Mr. Hughes's association with Bradford began in 1911, when he was appointed resident surgical officer at the Royal Infirmary.

It will be recalled that in 1941 the shortage of supplies necessitated the making of Orders by the Minister of Health and the Secretary of State for Scotland which limited the use of liquid paraffin in emulsions to not more than 25% by volume. As supplies have now improved these Orders have been revoked as from July 26, 1945.

The Medical Women's Federation will be glad to hear from medical women who, on demobilization from the Services, are faced with any difficulty on re-entering civilian life on which they desire advice. The Federation can loan money on easy terms in sums up to, say, £100, to suitable applicants who contemplate doing post-graduate study, or who wish to undertake medical work which involves monetary outlay. All inquiries should be addressed to the Secretary, Medical Women's Federation, 73, Bourne Way, Hayes, Bromley, Kent.

In future Service men and women who need sanatorium treatment for tuberculosis will be retained in the Services for a period not exceeding eight months from the date of their first absence from duty on account of the disease. This postponement will benefit the person concerned from the standpoint of his Service rights and privileges.

The National Institute for the Blind is sending an expert, Mr. Eric Boulter, to Greece to conduct a survey for the Greek Government of the special rehabilitation needs of the blind—both those who were born blind and those who have been blinded during this war. This visit has been arranged by U.N.R.R.A., to whom Mr. Boulter has been lent for two months. It is part of a rehabilitation programme in which U.N.R.R.A. is actively taking part in Greece. As a result of the 1940-1 war and the recent fighting there is a great problem in caring for and rehabilitating casualties; not only soldiers, but the many civilians and children who have been disabled by the war devastation in Greece. The Greek Government is fully aware of the size of this problem, and the urgent need to tackle it. The Ministries of War and of Health and Welfare, which are the responsible bodies, have asked U.N.R.R.A. for advice and assistance. The Director of Health of the U.N.R.R.A. mission is Dr. J. Kirk.

Sir Lawrence Bragg was present at a ceremony at Leeds University on July 20, when a tablet paying tribute to his father and himself was unveiled in the vestibule of the Brotherton Library. The inscription reads: "Near this place, in the old Physics Laboratory, in the year 1913, William Henry Bragg, Cavendish Professor of Physics in this University from 1909 to 1915, and his son, William Lawrence Bragg, began their joint researches and established with the first *x*-ray spectrometer the nature of *x*-ray spectra and the principles of crystal analysis, for which they were awarded the Nobel Prize in 1915." The tablet was presented by Mrs. Smithells, widow of Prof. Arthur Smithells, former professor of chemistry at the University. Prof. Smithells was a close colleague of Sir William Bragg, and it was his wish that the tribute should be made. During the ceremony Sir Lawrence presented to the University one of Sir William Bragg's original notebooks.

Mr. Arthur Selby McCrea, of Warley House, Halifax, who died on Feb. 26, aged 91, bequeathed his mansion at Warley, with an endowment of £50,000, to the Royal Halifax Infirmary.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* during the week notifications of measles fell by 894 cases, diphtheria by 74, whooping-cough by 66, scarlet fever by 31, and dysentery by 23.

The trend of whooping-cough notifications showed little change, except for relatively large declines in Cornwall (35 fewer) and Lancashire (27 fewer). The notifications of diphtheria were the lowest ever recorded, and 28 fewer than the previous low level recorded last summer. During the week a fall in incidence was recorded in every county except Lancashire and Yorkshire, where the incidence remained almost stationary. An increase of 42 in the notifications of measles in Suffolk was the only sizeable exception to the general fall in incidence. The largest returns for dysentery were Lancashire 38, London 24, Warwickshire 23, Essex 21, Middlesex 17, Surrey 15, Lincolnshire 11.

In *Scotland* there was a rise of 33 in the notifications of dysentery, and a fall of 36 in those for scarlet fever. The only new outbreak of dysentery was in Ayr County, 16 cases, and the largest increases were in Aberdeen County, from 2 to 14, and in Glasgow, from 10 to 21.

In *Eire* the only changes of any size in the returns occurred in Dublin C.B., where 63 cases of infantile diarrhoea and enteritis, and 42 of whooping-cough, were notified.

Scottish Vital Statistics

The preliminary statement by the Registrar-General for the second quarter of the year shows that the birth rate has continued to fall, and at 17.5 per thousand was the lowest rate recorded for a June quarter. The marriage rate has risen to 9.6 per thousand, and was the highest rate for any quarter since the first quarter of 1942. The death rate, 11.9 per 1,000, was slightly above the corresponding quarter of 1944, but with that exception was the lowest for any second quarter.

Week Ending August 4

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,232, whooping-cough 1,072, diphtheria 360, measles 2,190, acute pneumonia 234, cerebrospinal fever 39, dysentery 324, paratyphoid 3, typhoid 7, poliomyelitis 21.

No. 30

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 28.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

* *Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for:* (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week)

Stillbirths	196	22	31			217	14	34		
Rate per 1,000 total births (including stillborn)			32					34		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Owing to movements of population, birth and death rates for Northern Ireland are still not available.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London.*

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Nocturnal Cramp

Q.—*Can anything be done to prevent the onset of nocturnal "cramps" in the feet and legs in a woman of 35? What causes them? A femoral thrombosis has been present in the right leg for over ten years, but the spasms, which are extremely painful, affect either limb, and seem to be more likely to follow a day when more walking than usual has taken place. There are no varicose veins.*

A.—The spasm probably results from the presence of the products of muscular metabolism which have not been removed. It might be worth while massaging the muscles before going to bed. A hot bath might be helpful in preventing attacks. The precipitating factor is often postural, and difficult to avoid in sleep. Amyl nitrite might be worth a trial in order to relieve the attack. In any case very little is known about cramp; the condition is hardly conducive to deep personal study, and too fleeting and erratic in other persons.

Carbarsone

Q.—*What exactly is carbarsone, and what are its uses? In what form is it administered, and what is the dosage? Has it been found of use in treating asthma? What are the contraindications, if any, in using it in a case of asthma?*

A.—Carbarsone is *p*-carbamido-benzene arsonic acid. It is closely related to tryparsamide and acetarsone. Its main use is in the treatment of amoebic dysentery. It is marketed in tablets or capsules, and the adult dose is 0.25 g. taken by mouth twice daily for ten days. It is usual to institute a rest of ten days, and then the course of carbarsone may be repeated, and so on. The organic arsenicals are a specific remedy for tropical eosinophilia, and carbarsone has been used in this disease. Tropical eosinophilia, which is characterized by bronchitis, asthma, and a high blood eosinophilia, has been ascribed to infestation of the air passages by mites, though this explanation is not generally accepted. The writer has seen a similar condition arising in this country and responding to organic arsenicals. There is no evidence that organic arsenicals are of any value in the classical type of asthma, and it would not seem desirable to use carbarsone in asthma unless there were at least 2,000 eosinophil leucocytes per c.mm. of blood.

Hiccup in Infancy

Q.—*What are the aetiology and treatment—preventive and curative—of hiccups in the infant? A well-developed male infant 10 weeks old, 8 lb. 7 oz. at birth, now 12½ lb., who has been fed in turn on breast, humanized, full-cream, and again humanized food, hiccups just before and after almost every feed. The usual precautions of temperature, size of teat hole, and sitting the child up well have been attended to. Is it advisable to resort to a starchy food in spite of its supposedly rachitic properties?*

A.—The cause of hiccup in infancy is unknown. Probably the pressure of the full stomach on the diaphragm has something to do with it, and the stomach may be full of food after a meal or full of swallowed air before a meal. It is doubtful if the nature of the food used has anything to do with it, and it is a pity if, as may have occurred in this case, breast-feeding has been discontinued because of the hiccup. As regards feeding in the future, it does not appear to matter what is used, and there is certainly no indication for starchy food. A simple milk and water mixture with added sugar would be best (boiled cow's milk 4 oz., water 1½ oz., sugar 1½ teaspoons). The weight-records suggest overfeeding, and this may have started the tendency to hiccup. The present management suggested is to give the child a sedative (choral gr. 2) 15 minutes before each feed, and to see that the feed is taken in 15 to 20 minutes, with breaks for getting up the "wind" about twice during the feed and again at the end. It is likely that the symptom worries the mother (and doctor?) more than the child.

Effectiveness of Phthalates

Q.—*What is the relative effectiveness as insect repellents of the dimethyl, diethyl, and dibutyl phthalates? What is their relative toxicity to the human if rubbed on the skin? For how long is a skin application effective? Is there any danger to the eyes?*

A.—There is at present no published information on the relative effectiveness of dimethyl, diethyl, and dibutyl phthalates as repellents, and I do not know of any on their relative toxicity to man. None of them is dangerous if rubbed on the skin as directed. While there should be no serious danger to the eyes, all of them are liable to cause considerable smarting if they get into the eye. The duration of effectiveness of skin application will depend on temperature, amount of perspiration, etc., and it may be effective for longer with some insects than others; but in all cases it is a matter of hours.

Penicillin in Ulcerative Colitis

Q.—*Has the treatment of ulcerative colitis by penicillin been investigated, either by colonic washouts with a solution, or otherwise? If so what have been the results?*

A.—It has been asserted categorically in the U.S.A. that penicillin given by intramuscular injection has no effect on ulcerative colitis. Introduced directly into the lumen of the lower bowel, penicillin is rapidly destroyed, since *Bact. coli* and other organisms present there produce an enzyme—penicillinase—which has this effect. It should theoretically be possible to suppress the normal flora with such a drug as succinylsulphathiazole, and thus enable penicillin to persist and exert an action on surviving micro-organisms, but there is no evidence that even this proceeding has any effect on the course of the disease. There is some doubt whether bacterial infection *per se* is the cause of ulcerative colitis, and in any case the nature of this infection is undetermined; there are therefore no good reasons for expecting benefit from treating it with penicillin.

Endometrioma in Small Intestine

Q.—*A married woman of 37 complains of pain in the right iliac fossa, nausea, and constipation. This had occurred in bouts and had allegedly been coming on for "several years." She had one child of 16; no miscarriages; menses 6/20; regular and heavy with bearing-down pains. No frequency of micturition or loss of weight. Physical signs were compatible with acute appendicitis, and I operated. The appendix was normal, but she had a carcinomatously hard swelling, the size of a walnut, in the ileal wall. Resected terminal ileum, caecum, and ascending colon, and carried out an anastomosis of the ileum with the transverse colon. The uterus was symmetrically enlarged to the size of about a two-months pregnancy, but I took this to be an ordinary fibroid condition. She has made an uneventful recovery, but to my surprise the pathologist's report on the resected tumour was: "Shows a deposit of uterine adenomyoma." The tumour was relatively mobile and not fixed to the uterus, or near it. Should the uterus be removed, and, if so, how soon? And what is the prognosis? Will other deposits, if they exist, clear up when the origin is removed?*

A.—This is an interesting example of the occurrence of an endometrioma in the small intestine. The fact that such deposits occur is not generally known, though gynaecologists have for some time been discussing and writing on the subject. Any such deposit of an endometrioma will clear up completely if the ovarian activity be destroyed, either by removal of the ovaries surgically or by the administration of a castration-dose of *x* rays. In this case, therefore, there should be no need to advise the removal of the uterus.

Dermatitis of Navel

Q.—*A married woman aged 42 has for the past 8 months had a dermatitis of the navel. The condition is confined to the small area of skin inside the navel orifice, and goes through a regular cycle of desquamation when a thick layer of epithelium separates, leaving a pink, moist surface and slight serous discharge. Any treatment so far tried makes little difference.*

A.—This may be a local infective condition, and fractional doses of *x* rays and the following ointment would help:

Acid. salicyl.	gr. 5
Gentian violet	gr. 2½
Halden's emulsifying base	āā ad ℥j
Paraff. moll.	

Ft. ung.

It may be a local expression of a general disturbance, probably seborrhoeic eczema or psoriasis. In that case attention to general factors—endocrine, metabolic, or focal infections—will also be necessary.

Alkaline Tide in Urine

Q.—*What is the cause of post-prandial and morning alkaline tide? It is stated by some authorities that post-prandial alkaline tide acts as a compensatory mechanism against the loss of acidity during digestion, but this appears unlikely, as the same phenomenon is witnessed in patients suffering from gastric anacidity.*

A.—The alkaline tide in the urine is so exactly correlated with a rise of CO_2 in the alveolar air, and a rise of bicarbonate and a fall of chloride in the serum, that it is generally agreed that it is caused by the excretion of hydrochloric acid in the stomach. All these phenomena are diminished or absent in conditions of hypochlorhydria or achlorhydria, though some changes occur in urinary acidity as a result of the food absorbed. The reason that the tide is most marked after breakfast is that with later meals the alkaline tide from the second meal is obscured by the absorption from the intestines of acid excreted after the first.

INCOME TAX

Purchase of New Equipment

P. understands that recently concessions were made to the medical profession by an allowance for the cost of new equipment.

*** The rule of law is that replacements and repairs of equipment are allowable, but not the cost of increasing or improving the equipment; some purchases, of course, involve both elements, and the cost then has to be divided on some reasonable basis. We are not aware of any concession to the medical profession in this matter. The Income Tax Act, 1945, should benefit practitioners by giving a more effective allowance for future (and some recent) purchases, but that Act does not come into operation until some future date which has not yet been decided by Parliament.

Cost of Postgraduate Course

W. H. is practising in partnership, and has claimed as a deduction the cost of attending a postgraduate course. The inspector of taxes has refused the deduction, quoting in support of his view the judgment in Simpson *v.* Tate.

*** The case quoted dealt with the rather more stringent language used in Schedule E: "wholly necessarily and exclusively in the performance of the duties" as compared with "wholly and exclusively . . . expended for the purpose of the . . . profession. . . ." in Schedule D. Some of the grounds for the decision in Simpson *v.* Tate are consequently hardly applicable in our correspondent's case. On the other hand the language used by the learned judge was unusually general and sweeping, and, further, there may often be an element of "improvement" rather than restoration of professional knowledge and skill which might invoke the argument that a postgraduate course is to some extent at least an investment of capital in the individual rather than a replacement of something he has lost. For these reasons, though the point is open to doubt, we have not felt justified in advising those affected to test the question by an appeal which might involve the expense of a test case in the courts.

Retirement from Colonial Service

M. M. is very soon due to retire from the Colonial Service and has been on leave in this country since February, 1945. (It is assumed that he will remain here until and after retirement.) What will be his liability for the year from April 5, 1945?

*** He will rank as a British resident for this year and will be liable as follows: (*a*) Salary, to the extent to which it is remitted to or paid in this country. (*b*) Income from colonial investments, on one year's income measured according to the amount arising in the year to April 5, 1945. (*c*) Pension, on the amount receivable. No special rate of tax is chargeable; M. M. will be entitled to the usual allowance—personal, life assurance, earned income, etc.—and will be liable at 6s. 6d. in the £ on the next £165 of his income and at 10s. in the £ on the balance.

Repayment of Tax on an Annuity

"LONDON" pays his parent an irrevocable annuity of £120 per annum. How is income-tax relief obtained on this sum?

*** What "London" has done is to transfer £120 of his own income to his parent; the £120 is the parent's income and the extent to which tax is repayable thereon will be determined by his or her circumstances—i.e., what allowances are due and what other income, if any, he or she may have. It is presumed that "London" deducts tax at standard rate from the payments he makes. If so—and that is the correct legal course—he is fully recouped for the tax he pays on the £120, and in due course the parent claims the excess of the amount deducted as tax over his or her actual liability.

LETTERS, NOTES, ETC.

Sleep-walking

Dr. ANGUS MACKAY (Manchester) writes: Dr. C. Ismail (July 21, p. 108) suggests a precautionary measure to be taken in order to prevent sleep-walking in the case of a girl, and the remedy he offers consists in placing a basin containing cold water by the side of the bed in readiness to receive the foot of the ambulatory sleeper. In his experience the unconscious automatism of the motor cortex responds instantaneously, and stationary insomnia prevents any further peregrinations—provided the basin of water has been placed with mathematical precision over the exact floor area which would otherwise contact the descended foot, and provided the inevitable incoordinated postural attitudes were immediately corrected, although he does not mention these possibilities. If one accepts the aphorism that "prevention is better than cure," I very much doubt that this preventive method for cases of somnambulism, which Dr. Ismail assures us is not only the simplest but the best procedure, can be regarded as superior to all others or in any way curative. Disturbances of sleep are one of the commonest problems which confront the paediatrician, either as "nightmares" and "night terrors" or as actual "sleep-walking." The latter simply occurs when efferent impulses from those mnemonical areas of brain tissue (Semon's areas of "engrams") are sufficiently strong to impress the motor cortex with locomotor action. But a neurosis is present in all of these abnormalities. Surely the prevention of this particular disease which Dr. Ismail describes "falls" into the depths of a warm-blooded psychiatrist rather than a basinful of cold water.

Dr. A. OWEN-FLOOD (London, N.8) writes: Dr. C. Ismail gives us an interesting method of preventing sleep-walking. Nocturnal somnambulism and the somnambulistic stage of deep hypnosis are identical: the former yields readily to suggestion under the psychic state. It is not to be forgotten, however, that "walking" is but a symptom and should not be removed without first investigating and correcting the underlying mental unrest causing the condition. Care should be taken to expose "fake" walkers, and I have found sleep-walking a not uncommon symptom in genuine mental epileptics.

"Trigger Finger"

Mr. F. W. M. PRATT, F.R.C.S. (London, W.1), writes: "Trigger finger," referred to in "Any Questions?" (July 21, p. 106) appears to have become more frequent among adults during the last few years, and I think can well be classified among the industrial diseases. Occupations involving pressure on the palm of the hand are to blame. The majority of cases show a localized area of tendinitis at the level of the metacarpo-phalangeal joint of the third or fourth finger. Stenosis of the flexor sheath in my own experience is relatively uncommon. Treatment should be limited to a linear incision of the sheath, which should not be sutured; in fact it is impossible to do so. The results of this operation are excellent.

Novelists' Resuscitation after Drowning

Mr. FRANK T. LAND (Glasgow) writes: Dr. John Yates (July 28, p. 144) draws attention to an old method of resuscitation after drowning which he had encountered in Baring-Gould's *The Vicar of Morwenstow*. It entailed "throwing the victim across a barrel," and presumably following a technique analogous to the modern one of artificial respiration by rocking. This method was apparently popular at one time and is referred to by Dickens in *Our Mutual Friend*. At the reanimation of Rogue Riderhood "Captain Joey . . . a pupil of the much respected old school . . . favours the doctor with a sagacious old-scholastic suggestion that the body should be hung up by the heels, 'sim'lar,' says Captain Joey, 'to mutton in a butcher's shop,' and should then, as a particularly choice manœuvre for promoting easy respiration, be rolled upon casks."

X Rays and Prostatic Hypertrophy

Dr. J. H. DOUGLAS WEBSTER writes: Your annotator on this subject (July 21, p. 105) airily dismisses it, and most urological textbooks give it a very brief reference. The "evidence" your authority turns a blind eye towards, and therefore asserts doesn't exist, is to be found in the textbooks on radiotherapy (as Guilbert, Solomon, Perussia, and Holthusen) and in the many special papers on the subject, as those by Barringer *et al.* (*Amer. J. Roentgen.*, 1934, **31**, 350) and by Burnam (ibid., 1938, **39**, 175). Guilbert (1932) said that 60% were relieved and their disease was arrested; Barringer *et al.* found that 30% of cases which otherwise would have soon come to operation were relieved; Burnam found that more than 50% had relief "symptomatically, as well as from the standpoint of objective findings." There are about 17 references to the subject in the *Index of Radiology* (1923–42). My own experience for over twenty years has been similar to that of those mentioned above; several of my patients have been followed up for over ten years with no further advance of the disease. The value of x rays in the benign prostatic field is nearly as great as in the similarly too-little-used field of uterine fibroids. Much of the early bladder trouble is due to spasm or congestion ("edema"—Barringer); these are usually quickly allayed by x-ray treatment and operation avoided. All early prostate cases might well have a suitable course of x-ray treatment; for in a considerable percentage this would be found to be a prophylactic against further troubles. Pituitary irradiation might help some cases (as in uterine fibroids).

An Eyeless Needle

Dr. **Wright Lambert** (Keighley) writes: In reply to Mr. J. L. Aymard's letter (July 14, p. 74) he may be interested to know that I devised a needle-holder to facilitate threading, and holding, a tubular needle such as he has been using. My description appeared in the *Lancet* of Oct. 21, 1944, p. 536. The holder can be supplied by Down Bros., London, who also supply needles of all calibres and shapes to fit the holder, which will also take an ordinary hypodermic needle.

Prolapsus Ani in a Child

Mr. **F. W. M. Pratt**, F.R.C.S. (London, W.1), writes: I was interested to read the list of methods of treatment for this condition given in "Any Questions?" (July 21, p. 105). It is really time that most of these methods were forgotten or banished from textbooks. For instance, nothing could be more ineffectual or productive of hysteria in both parent and child than to order defaecation in the lying position. As the writer says, many cases undergo spontaneous cure and need no treatment, but there are also many cases which are persistent and should be given active treatment. I do not think that a psychological state is a common factor; diarrhoea certainly is. The following method of treatment is most effective. Under vinesthene anaesthesia 0.25 to 0.5 c.cm. of absolute alcohol is injected into each quadrant of the anal submucosa through a proctoscope, as in the injection treatment of haemorrhoids. No preliminary enemata or wash-outs are given. I have used this method for about the last eight years, and in nearly every case have had an instantaneous cure. In a very few cases this injection has had to be repeated on one other occasion.

Fox-Fordyce Disease

Dr. **John T. Ingram** (Leeds) writes: In my experience Fox-Fordyce disease (Aug. 4, p. 171) is responsive to oestrogen therapy, and responsive to this only.

Visiting at Children's Hospitals

Dr. **L. A. Parry** (Hove) writes: A children's hospital is examining the desirability of allowing a daily visit to their children instead of, as at present, twice a week. I shall be very grateful if any children's hospital which has adopted the daily-visit system will give me information as to how it is working, especially in connexion with the incidence of infection, and the psychological effects on the children.

Adder-bites

Dr. **T. V. Cooper** (Dorchester) writes: In the *Journal* of July 7 there is a question and answer dealing with adder-bites. The answer advises the use of antivenomous serum subcutaneously. Why did not the adviser advocate serum intravenously? Adder-bites are not uncommon in this area. Among Service personnel I have heard of as many as three cases in one day during manœuvres on heath land. At the time of which I speak serum was not available, but I never heard of a fatal issue. Serum is now available on a small scale (see *B.M.J.*, Aug. 4, p. 172). I make a practice of holding a small stock. Under refrigerator conditions I regard, perhaps wrongly, this serum as being potent for use for at least 4 to 5 years, not the one year mentioned in the answer. The Pasteur Institute, who make the serum, give a keeping period exceeding four years. Within the past few weeks I saw an airman home on leave who received an adder-bite while out shooting rabbits, in which a delay of about two hours occurred before he was brought to the hospital; 10 c.cm. of serum intravenously when seen and a further 10 c.cm. four hours later appeared to cut short the systemic symptoms, and he was well enough to go about in four days.

⁂ Our adviser replies: Calmette in his authoritative work on venoms (1908, p. 263) recommends that the antiserum against snake-bite should be injected into the subcutaneous tissue of the abdomen; on page 265 he remarks: "In cases in which phenomena of serious intoxication have already appeared, and when asphyxia threatens, one must not hesitate to inject 10 or even 20 c.cm. of serum directly into a vein." So there is authority for intravenous injection in urgent cases. As regards the length of time during which the serum remains potent, I gave one year as a conservative figure.—Ed., *B.M.J.*

"Doctor" or "Medical Practitioner"?

Dr. **C. R. Moore** (Bray) writes: The restrictions on the use of the term "nurse" reported in the *Journal* of July 28 (p. 130) make one wonder how long it will remain customary to use the term "doctor" to connote registered medical practitioner. The latter description satisfies most of us, and it seems hardly in keeping with the dignity and ethics of the profession to be inaccurate.

Active Practice of Medical Women

Three Final-year Medical Students write: With reference to the large proportion of women taking the medical course—approximately one-third in the final year in our university—it would be of interest to know, on available statistics, how many of these are likely to be actively practising at the end of three or five years after qualifying.

The Shortage of Nurses

Three Sister-tutors, **I. G. Morse, J. Eyre**, and **E. M. Stone**, write: Much attention has recently been given to the shortage of nurses. In actual fact, how great is this shortage and how can it best be overcome? The urgent need of the moment is to recruit domestic workers and to provide the hospitals with trained orderlies; in this way nurses and student nurses will be freed from extraneous duties and will be able to devote their energy to the nursing of patients. For the provision of trained orderlies one scheme has already been suggested: that the Ministry of Labour should set up a national auxiliary service for hospitals, and through this establish courses of training for prospective hospital workers. It is obvious that the domestic duties now performed by nurses must, when given over, be given into other capable hands. Adequate remuneration and good working conditions will be essential to the success of the scheme. At this moment, when massive redistribution of labour is in progress, the time is ripe as never before to establish this new and most necessary grade of hospital worker.

Tuberculous Persons in Prisons

"C.438" writes: Dr. Audrey Roberts (July 21, p. 100), after discussing work done in prisons by prisoners with tuberculosis, asks whether modern prison conditions may be accounted aetiological factors in the disease. My experiences in a prison in 1942 may be of interest, though the term "modern" needs some qualification, since the prison was built 100 years ago, presumably under the influence of the attitude towards crime prevailing at that time. Most of the day, actually 19 hours, including an unbroken period from 4 p.m. to 6.30 a.m. (except when doing special overtime work), was spent in the cell. (I learn that since 1942 supper time has been altered to 5 p.m., so reducing the evening cell period by one hour.) During this time all urine passed, washing-up water, etc., remained until the morning. Though the size of the cell was adequate, the window space was definitely not so. If the cell faced north the occupant was unfortunate in not having any sun during this time. Even when more favourably placed, the smallness of the window combined with its height from the floor (intentionally too high to allow seeing out without standing on a chair—a punishable offence) and the extreme thickness of the walls and bars made it impossible to sit in the sun for more than a very limited period, and then only by following the patch of light in its arc across the cell. Unless one were fortunate enough to be in an outside work-party the two 1/4-hour exercise periods daily were the only time spent out of doors. On wet days exercise consisted of walking round inside landings. Sanitary conditions were primitive, and mattresses and blankets were the legacy of the previous occupants, though clean sheets were given fortnightly—on two occasions palpably damp. Added to this the food was low in quantity and especially lacking in green vegetables, with fruit of any kind practically non-existent. It was noteworthy that the extra slice of bread and cup of cocoa received for three hours' heavy overtime work on hand-loom weaving were cut off, so that we received the same food as those doing shorter hours of sedentary work. Conditions must vary from one prison to another (the one cited was in no sense a reform prison), and they must have been much aggravated by wartime restrictions—e.g., short staffs, rationing, and the blackout. Whatever the reasons, such were the conditions. Unfortunately it is difficult to assess their effect on the health and on the incidence of tuberculosis, since no medical examination was made on discharge.

Correction

In the article by Prof. S. Sarkisov in the issue of July 14 (p. 37) it was stated that bio-electrical investigations (electro-encephalograms) had been carried out in England by Adrian, Matthews, Walter, Ultridge, and others. The name Ultridge was inserted in error, and the name of Williams omitted.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 25 1945

SEQUELAE OF CEREBROSPINAL MENINGITIS

A FOLLOW-UP STUDY OF 986 CASES*

BY

JOHN A. DEGEN, jun., M.D.

Captain, Medical Corps, Army of the United States

WITH THE ASSISTANCE IN THE FIELD OF

HELEN CAMERON, R.N.† VIRGINIA L. M. ROBINSON, R.N.

AND

MILDRED S. R. WIEDEN, R.N.

The present survey was designed primarily to answer a single question, "Is there an appreciable incidence of persistent symptoms following cerebrospinal meningitis, and, if so, what are the nature and the severity of these symptoms?" The term "symptoms" is used advisedly, and refers to the subjective sensations and feelings of the patient as opposed to specific pathological states or conditions. The data here presented are therefore based solely on the statements of the patients themselves. It would obviously be highly desirable to carry out a medical check-up as well, but lack of necessary facilities and of medical personnel unfortunately made such a procedure impossible.

The area chosen for the survey comprised three geographically distinct districts. The chief of these was in south-east Wales and Monmouthshire, the lists of patients being supplied by two large city isolation hospitals (at Cardiff and Newport) and five smaller isolation hospitals in coal-mining towns of southern Glamorganshire (Bridgend, Caerphilly, Gelligaer, Pontypridd, and Rhondda). Two smaller areas were added by way of contrast—the Denbighshire region served by the Wrexham Isolation Hospital, and the largely rural area from which patients were sent to the Carmarthen County Isolation Hospital at Carmarthen. The numbers of cases from each of these hospitals are shown in Table I.

TABLE I

Hospital	Number of Cases on Original Lists	Meningitis Cases Excluded from Series: Untraced or Unlocated	Left District	Died since Hospital Discharge	Excluded due to Insufficient Information	Number of Cases in Present Series
Cardiff City Isolation Hospital ..	416	9	17	5	20	365
All-yr-yn Hospital, Newport	144	—	2	1	7	134
Tyntylo Isolation Hospital, Rhondda	127	1	—	1	2	123
Bridgend Isolation Hospital	63	8	4	—	11	40
Gelligaer Isolation Hospital	28	—	1	—	—	27
Caerphilly Isolation Hospital	29	3	—	—	—	26
Tonteg Isolation Hospital, Pontypridd	21	—	—	—	1	20
Wrexham Isolation Hospital	156	—	2	—	12	142
Carmarthen County Isolation Hospital	124	—	2	5	8	109
Total	1,108	21	28	12	61	986

Each of the nine co-operating hospitals furnished the names and addresses of all cerebrospinal meningitis patients admitted during the calendar years 1940 and 1941, and in some cases during the first three months of 1942. The field survey was made during the period from May 21 to June 25, 1942, inclusive. The interval between hospital discharge and follow-up visit thus varied from 3 to 29 months, but tended to approach the longer extreme. Over one-half of the series were followed up more than 18 months and 84% more than a year after discharge, while only 4% had been out of hospital less than six months.

Technique of the Survey

A similar follow-up survey of cerebrospinal meningitis patients in London had previously been made by the Ministry of Health (Maddock, 1943). In order that the incidence figures for sequelae in urban and rural areas of Wales and Monmouthshire should be comparable to those of the Ministry for metropolitan London, essentially the same field technique was again used, and home visiting was done by the same nurses as in the London study.

Follow-up visits were made by three Public Health nurses of the American Red Cross–Harvard Field Hospital Unit, with no advance warning of them. Each of the addresses furnished by the hospitals was visited, and the patient interviewed if possible. Otherwise, information was obtained from a member of the household or a neighbour who knew the patient; each such instance was subsequently reviewed, and those in which the informant did not appear sufficiently well acquainted with the patient's condition were not included in the survey. As shown in Table I, 61 cases were excluded for this reason, and another 61 because they could not be located, had moved from the area, or had died; this left 986 successful follow-up visits out of the original 1,108 meningitis cases.

The Public Health nurses gained a ready entry to the homes by introducing themselves as representing the hospital, which wished to know how the patients had been doing since their illnesses. Leading questions were scrupulously avoided, the only initial question asked being, "How have you felt since you had meningitis?" When this elicited no complaints of ill-health the query was repeated in somewhat altered form during the course of a few minutes' conversation, and if the reply was still the same the patient was recorded as having no disabilities. In analysing the data collected, sequelae were arbitrarily defined as disabilities persisting for over three months after hospital discharge. Symptoms previously present were excluded unless definitely accentuated immediately after meningitis, as were also subsequent symptoms that did not appear immediately after the illness. On the other hand, complaints that had disappeared before the date of the interview were included provided that they fulfilled the above conditions.

† Registered Nurse, U.S. Public Health Service.

Evaluation of the Survey Method

Before considering the findings, it might be advisable to examine the survey method briefly and to enumerate its chief advantages and disadvantages. These are essentially as follows:

Advantages.—(1) The primary aim of the method employed is to determine the incidence of symptomatic complaints such as personality changes, tendency to become easily fatigued, many headaches, and backaches, etc., for which no supporting evidence would be expected to be found on physical examination. (2) This method will also bring to light those patients not satisfactorily rehabilitated after their illness, whether this be due to organic cause, neurosis, or psychiatric abnormality.

Disadvantages.—(1) Although it would seem reasonable to assume that at least a large proportion of the disabilities reported were a direct result of the preceding meningitis, such an assumption rests on purely circumstantial evidence which, by its very nature, cannot provide proof of any causal relationship. *It cannot be too strongly emphasized that these sequelae are not presented as disabilities caused by the meningitis, but only as symptomatic disabilities, persisting for more than three months, which first appeared, or (if previously present) became accentuated immediately after the illness.* (2) Data based on the patients' own statements will unavoidably be subject to some degree of exaggeration, and will also undoubtedly include a number of genuine complaints due to causes other than cerebrospinal meningitis. (3) There would seem to be no conceivable way in which a control series could be studied. Even if a comparable group could be drawn up, any attempt at collecting similar information concerning health would almost surely be received with such suspicion as to render the results valueless.

The Survey Findings

General.—The incidence of the various disabilities according to age group and sex is shown in Table II. It should be noted, particularly in connexion with the youngest age groups, that the ages given represent age at time of illness, which was up to 29 months before the follow-up interview. A total of 387 individuals showed 657 disabilities; of these, 223 had only a single complaint, while 95 reported two each, 41 three, 21 four, 5 five, and 2 six. As we have said, the classification adopted is purely symptomatic; therefore no attempt has been made at diagnosis. Similarly, it did not seem justifiable to try to decide whether a given symptom was or was not due to meningitis, and all symptoms that satisfy the criteria stated above have been included.

TABLE II.—*Incidence of Disabilities Following Meningitis*

Age at Time of Meningitis:	Under 1		1 and 2		3 and 4		5–14		15–24		25–44		45–64		65 and Over		Total

Total	8	4	39	12	29	26	83	75	91	48	107	77	26	30	0	2	383	274	657

Emotionally Less Stable.—Under this heading were grouped those patients variously described as irritable, excitable, disposition poor or bad, nervous, high-strung, hysterical, or losing temper easily. In 24 of the 109, severe or frequent headaches or other pains were associated, which might easily explain the condition.

Depression.—Of these 15, 8 were described as depressed and 7 as moody or sulky.

Inability to Concentrate.—"Unable to concentrate" was the term used for 5 of these 14 individuals, while "loses self" and "absent-minded" each accounted for two. The other 5 more specific descriptions were "frequent mental lapses," "ignores conversation directed at her," "appears vacant and doesn't understand what is said to him," "doesn't understand directions well," and "unable since illness to cope with rationing while working in shop."

Poor Memory.—No further qualification was given for 8 of this group, while the other 5 were described as "memory for names worse," "doesn't remember things he is told," "can't remember where she puts things," "forgets things when sent to shop," and "notices it in figuring—mind goes blank."

Total Deafness.—The most striking feature of this disability is the extremely low age distribution, 6 of the 27 (22%) being 2 years of age or less, while 21 (78%) were not over 14. These percentages are slightly less than double the corresponding figures for the entire group of 387 with disabilities. Three patients totally deaf at discharge subsequently showed marked improvement, starting at three months, seven months, and eight months respectively. Specific mention of speech was made in 10 instances, 2 of these speaking well and 5 not as well as before the illness, while the remaining 3 were deaf-mutes.

Partial Deafness.—Here the young age distribution of the preceding group is not found. The deafness was described as moderate or severe in 10 of the 28 cases. In one case a persistently discharging ear offers a probable explanation for the partial deafness, both deafness and discharge clearing simultaneously six months after leaving hospital. Two of this group, both with only slight deafness, had scarlet fever within a few weeks of meningitis, leaving a field for speculation as to which illness the impairment of hearing is to be attributed.

Visual Disabilities.—This tabular classification represents a condensation of the following four headings:

(*a*) *Impaired Vision.*—Of these 22 cases 17 were reported as "weak eyes," while one each was described as "vision worse," "blurred vision," "near blindness in left eye, poor vision in right," and "eyes weak and red" (iritis and choroiditis on discharge from the hospital). The remaining patient, a boy of 14, had a retinal haemorrhage in the right eye while in hospital; after discharge he was in bed in a darkened room for six weeks and unable to see properly for five months, but since that time his vision had been normal.

(*b*) *Visual Disturbances.*—This term is used to designate four cases each presenting a different type of disturbance of visual function. These were double vision, clearing at 18 months and associated with partial deafness and tinnitus; night-blindness sufficiently marked to force the patient to return home before dark, associated with total deafness; spots before eyes frequently; and frequent visual disturbances described rather vaguely by the patient's mother as being in the form of "black spells," associated with severe headaches and strabismus.

(*c*) *Enucleation of Eye.*—This operation was performed in two instances. One of these patients had choroiditis as a complication while in hospital, and the eye was enucleated three months later. The other was transferred direct from the isolation hospital to a general hospital for the operation, the patient not knowing the reason for this procedure.

(*d*) *Total Blindness.*—The single case of total blindness was that of a female infant of 8 months who was totally blind for five months after discharge, but subsequently recovered her sight. She was also in bed for six months after leaving the hospital, unable to sit or walk, but at the age of 32 months (the time of the follow-up visit) could walk alone holding on to a wall, though seeming to have no co-ordination or balance and still having to be fed. (In the absence of further clinical data, the latter disability could only be given the admittedly unsatisfactory classification of "poor balance.")

Strabismus.—The age distribution is again very young, five of the nine being 4 years of age or under. The condition was unilateral in five and bilateral in one, while in the remaining three this point was not specified. In two instances this disability was no longer present—one as a result of operation three months after discharge, the other clearing spontaneously twelve months after illness. The latter patient was a 13-months-old male infant who at the time of follow-up (aged 37 months) showed evidence of markedly retarded development, and was observed by the interviewing nurse to be apparently hydrocephalic.

Tinnitus.—These four individuals were all over 24 years of age, and in all of them the tinnitus was associated with deafness—total in one and partial in the other three.

Excessive Lacrimation.—This was associated with impaired vision in two of the four instances.

Other Impairment of Special Senses.—Aphasia was reported twice (both in individuals over 50) and slurred speech twice, while one female aged 75 complained of complete loss of sense of taste for six months after discharge.

Pains in Limbs and "Rheumatism."—Pain in the lower limbs was complained of by 19 of the survey group. Pain, soreness, or aching of the legs was the complaint of 12, in one case accompanied by stiffness. Three had experienced "arthritis" or "neuritis" of the knee, three others had both pain and swelling of the knee, while the symptom of the remaining patient was periodic swelling of knees and ankles. In four instances it was specifically stated that the disability had interfered with work or attendance at school.

Pain in the upper limbs occurred three times, in the form of aching of arm, "arthritis" of arm, and "neuritis" of shoulder. Three further cases classified as "rheumatism" represent generalized joint or other pains that could not be localized to any one anatomical area.

Weakness of Limbs.—Weakness of the lower limbs was reported eight times, the weakness being in the ankles in three, the knees in one, and the leg muscles in four. One of the latter group had weakness of arms as well as legs, and this combination has been classified as two separate disabilities; this case is one of the two described below. There were two cases of weakness of the upper limbs, both presenting points of individual interest. The first was a female aged 65 who lost the use of her right arm completely for six months following meningitis, with subsequent marked improvement, although 24 months after discharge she was still unable to lift heavy objects. The other was a male aged 52 with extreme weakness of arms and legs for six months after his acute illness. There was no pain or stiffness, but he could not use his arms to lift anything and was unable to work. The condition cleared spontaneously after six months, and for 15 months he was asymptomatic. Then, 21 months after discharge, he developed "fibrositis" of arms and legs with pain and stiffness, and at the time of the follow-up had been completely incapacitated for six months. (The pain and stiffness have, of course, not been included in the survey findings, the later development being related here solely as a matter of interest.)

Lameness and Unable to Walk.—Two of the six cases grouped as lame were described as "turns foot out" and "throws foot out when walking." Two others reported marked limping, one case clearing completely at six months and the other being much improved when interviewed 15 months after discharge. A male infant of 9 months at the time of illness was unable to straighten his leg; he did not walk until he was 18 months old, and though by the age of 27 months (when followed up) he ran about and played, he always kept his leg bent at the knee. The remaining child, a girl aged 6, suffered from stunted growth in her left leg, with a severe limp and muscles that at times were tender to touch. On the basis of information available two patients could only be classified as "unable to walk." A girl aged 6, also totally deaf, was in a push-chair for six months after her attack of meningitis, with subsequent complete recovery. A boy aged 3 was unable to walk on return from the isolation hospital, and in two weeks was admitted to another hospital; 13 months later he was said to be still there with a cast from the waist down.

Headache.—This is by far the most common disability of the series, and was reported by 170 of the survey group. There were associated visual disabilities in only 13 of these. Defining "frequent" for purposes of tabulation as weekly or oftener, this symptom was divided into four main subgroups, as follows:

Mild or moderate, occasional	61
Mild or moderate, frequent	61
Severe, occasional	30
Severe, frequent	18

Space does not permit a detailed analysis of the headache symptomatology, but the findings in respect of each of the four chief characteristics of this symptom are briefly presented.

(*a*) *Severity.*—Ten cases were reported as mild, slight, or not severe, and an additional 10 as dull. These and the 93 cases in which severity was not specified (and so presumed to be mild) give a total of 113. Moderate headaches numbered nine, while 48 were described as sharp or severe.

(*b*) *Frequency.*—In six cases headaches were constant, while in 36 they were termed "frequent" by the patient or informant. More specific frequency was twice a week or oftener in 10, approximately once a week in 27, and less often than weekly in 28. Of this latter group there were only four patients who did not have their headaches at least once a month. Occurrence was described by 40 as occasional or "not frequent," while frequency was not specified in 10 instances. Eight headaches occurred when the patient was hot, tired, or excited, and five were subject to other miscellaneous exciting causes.

(*c*) *Duration.*—This was the least satisfactorily reported characteristic, 107 not specifying the duration of their attacks. Of the remainder, six were constant, 28 lasted between a day and a week, 18 for 2 to 4 hours (including "several hours"), and 11 for one hour or less.

(*d*) *Location.*—In 39 instances location was not specified. The headaches were frontal in 79 (46% of the 170), occipital in 22, "top of the head" in three, and temporal in one. The location was described by 16 as various combinations of two of the above, and by 10 as generalized.

Easily Fatigued.—Of these 48 complaints 40 were described as easily fatigued or tiring easily, three as sleepiness during the day, two as listless or languid, two as lack of energy, and one as "tired bouts." A specific statement that time had been lost from work or school as a result of this disability was made by six individuals.

Backache.—Since backache is essentially a rather vague sort of symptom, it was perhaps to be expected that the description of this disability would be similarly vague and relatively unsatisfactory. Frequency was not specified by 11 of the 46, while eight described their backache as constant, eight as frequent, and eight as occasional. Daily, weekly, and monthly occurrence were each reported once; four experienced backache after heavy work, and four if tired. Neither severity nor duration was well enough described to warrant tabulation. The location (not specified in 18) was interscapular in one, low back in 24, and sacral in three.

Poor Balance.—Aside from the case previously described under "Total Blindness" this did not appear to constitute a serious disability, being variously described as "balance poor," "stumbles easily," "sways when walking," and "tendency to fall." Ten of the 20 cases were associated with deafness—total in five instances and partial in five. The disability had cleared completely in three (six months after discharge in two and 10 months in the third), and was improving in nine of the remaining 17.

Dizziness.—This group of 13 complained of dizziness, giddiness, or feeling "light-headed." Headache was also reported by nine of these individuals. Deafness was associated in only two instances (one total and one partial), and these two were the only ones of the 13 who complained of poor balance.

Miscellaneous Disabilities

This final group of what might be termed symptomatic odds and ends comprises all disabilities (excepting a few that have been grouped above with closely associated complaints) occurring less than 10 times. The greater number of these require no more than mention of their occurrence, but a few seem deserving of some further elaboration.

The nine gastro-intestinal complaints reported consisted of vomiting in five, poor appetite in two, and one each with persistent constipation and with a monthly attack of gastro-intestinal pains and upset. Neck pain, occurring in seven, was described five times primarily as pain and twice primarily as stiffness; headache was associated in four instances and backache in three. Nightmares and increased susceptibility to head colds were each reported five times, while there were three complaints of sleeping poorly.

"Heavy head" was a complaint encountered only in Denbighshire, and no further elucidation of the nature of the disability could be obtained from four of the five presenting this symptom. The fifth patient stated that he felt as if severe pressure were being exerted on the top of his head. This occurred chiefly when he was trying to get to sleep, and as a result he had very little sleep at night and was able to work only three or four days a week.

The four cases of retarded development included one boy of 22 months (3 years old at time of follow-up) described by his family as retarded in physical development, and three cases of mental retardation, all in males. One of these, 3 years old at the time of his meningitis and 5 at the follow-up, had been in a mental institution in London for over a year. The other two were aged 10 and 13 months at the time of acute illness, and were followed up 27 and 26 months later, respectively. Neither had walked or talked or shown any interest in toys, and the younger one was unable even to sit up. This child also presented a history of almost hourly convulsions for the first five or six weeks after discharge. Both patients were seen by the interviewing nurse, and the older was observed to have a disproportionately large head (previously mentioned under "Strabismus").

Of the disabilities occurring once or twice—listed in Table II as "Other Miscellaneous"—only two seem of sufficient individual interest to warrant a brief description. A male aged 39, suffering from facial nerve paralysis, had apparently followed his medical status with close attention, as he described his disability as paralysis of the fifth and seventh nerves, involving masseters and cheek muscles and causing protrusion of the lower lips as well as sensory disturbances of the mouth and tongue. This cleared spontaneously 11 months after discharge, and had not recurred when he was interviewed two months later. The other case was that of a male aged 41, suffering from palpitation which was present "all the time" but worse at night, with associated nightmares and irregularly occurring severe frontal headaches. As a result he slept very little, and had been unable to resume his work as fitter at a local colliery.

Disabilities reported twice were oedema of limbs, oedema about the eyes, fainting attacks, enuresis (in a girl of 6 and a male of 18), nose-bleeding, "not as robust as previously," persistently discharging ear, and restlessness. Those reported a single time (including the two described in the preceding paragraph) were paralysis of facial nerve, palpitation, convulsions, "lumps on back of head," "numbness at back of knee," and "nervous habit of shaking head."

Accentuation of Disabilities Previously Present.—Although it was decided that disabilities previously present should be included if definitely accentuated immediately after meningitis, only 6 such cases were found. Three of these complaints were of headache, two of impaired vision, and one of partial deafness.

Disabilities No Longer Present or Improved.—At the time of the follow-up 35 disabilities were no longer present. Nine of these had cleared four to six months after discharge, 11 during the second six months, 5 during the second year, and 10 from 25 to 28 months after leaving hospital. This list included headache and partial deafness (5 cases each), pain in the lower limbs (4 cases), "easily fatigued" and "poor balance" (3 each), and "emotionally less stable" and strabismus (2 cases apiece), while 11 other disabilities each numbered one recovery. There were 64 reports of disabilities that were still present but improved. Of these, 21 were cases of headache, 9 of poor balance, and 8 of partial deafness, while no other disability was mentioned more than four times in this connexion.

Health Improved Since Meningitis.—In contrast to the disabilities so far presented, the health of 61 individuals was said to have been better since meningitis. This improvement concerned general health in 58, while the other 5 were personality changes for the better. A boy of 4½ was no longer shy and retiring; a girl of 7 now played happily with other children; a girl of 12 "was grizzly before meningitis but has a happy disposition now"; while a girl of 15 "seems improved in disposition." But the most amazing transformation was that of a 51-year-old chronic alcoholic whose previous condition was described by his wife as "drunk morning, noon, and night." She fervently blessed his illness, for since having meningitis he had become a teetotaller, and for 25 months had not touched a drop of liquor.

Some Further Considerations

The major portion of this report has been devoted to a brief description of the survey itself and presentation of the disabilities found. There remains a large amount of associated data gathered by the interviewers in the field, much of which might prove of interest. However, limitations of space permit the selection of only a small part of this material, and four further points have accordingly been chosen to be touched on briefly. These are the interval between discharge from hospital and return to work or school, the occupations of the survey population, indication of those disabilities considered actually incapacitating, and the incidence of disabilities by occupational groups.

Interval Between Discharge and Resumption of Work or School.—This interval is shown in Table III, including the presence or absence of disabilities and sex incidence. It is obviously impossible to determine accurately the point at which an infant or pre-school child resumes normal activity, and these incidence figures are therefore

Table III.—*Interval between Hospital Discharge and Resumption of Work or School*

Time after Discharge when Work or School was Resumed	Patients without Disabilities				Patients with Disabilities			
	Male		Female		Male		Female	
	No.	%	No.	%	No.	%	No.	%
1st month	119	51·5	108	61·0	49	27·7	48	37·8
2nd month	66	28·6	45	25·4	58	32·8	34	26·7
3rd month	28	12·1	17	9·6	20	11·3	17	13·4
4–6 months	13	5·6	6	3·4	33	18·6	18	14·2
7–12 months	3	1·3	0	—	8	4·5	1	0·8
Over 12 months	0	—	0	—	1	0·6	2	1·6
Did not resume	2	0·9	1	0·6	8	4·5	7	5·5
Total	231	100·0	177	100·0	177	100·0	127	100·0
Pre-school	91		91		52		26	
Interval not stated ..	4		5		4		1	
Grand total ..	326		273		233		154	

based on totals exclusive of pre-school ages and the 14 persons for whom the interval was not stated. Taking three months as the maximum limit of a normal period of convalescence, it will be noted that there is a very definite delay in return to work among the group complaining of disabilities compared with those without complaints. The three intervals over 12 months were 13 months for the one male case and 14 months and 25 months for the two females.

Occupation.—A detailed list of the occupations of the survey population resulted in a table so enormous as to be wholly unwieldy, and the occupations have accordingly been condensed into the groupings given in Table IV. Among the males, as shown in the first column of this table, 62 were employed in colliery work, while 38 worked in factories, mills, and plants. The remaining male adults have been divided into "Other Heavy Labour" and "All Other Adults." For the females, housework is the leading occupation with 121, while "Factories and Mills," with 22, is the only other adult classification listed separately. The Services had 17 male representatives—15 Army and 2 Royal Air Force—while there was not a single member of the Auxiliary Services among the females. Three males and no females were unemployed before contracting meningitis, while occupation was not stated in four instances by males and in one instance by females.

TABLE IV.—*Incidence of Disabilities by Occupational Groups*

Occupational Group	Total No.	All Disabilities		Incapacitating Disabilities	
		No.	Rate per 100	No.	Rate per 100
Male					
Colliery	62	36	58·1	12	19·4
Factories, mills, and plants	38	20	52·6	3	7·9
Other heavy labour	41	18	43·9	3	7·3
All other adults	126	51	40·5	9	7·1
School	148	56	37·8	14	9·5

Number of individuals with disabilities	2	2	5	1	2	—	17	9	10	8	11	2	3	2	—	1	50	25	75

Incapacitating Disabilities.—In considering the complaints made by 387 of the 986 individuals followed up (an incidence of 39.2%) it is obvious that many of these disabilities are of a relatively trivial nature. In an attempt to determine how many were truly incapacitating, the record cards of all patients with disabilities were carefully reviewed. The two criteria employed were obvious interference with the patient's former occupation and marked likelihood of his being seriously handicapped. Total deafness was considered incapacitating *per se*, but with this exception the status of each case was decided on its individual merits. The disabilities classed as incapacitating are shown in Table V, with their age and sex distribution. A total of 91 incapacitating disabilities were present in 75 individuals, giving an incidence of 7.6%. The disabilities listed as "Miscellaneous," each occurring once, were (in ascending order of age) total blindness, poor balance, "rheumatism," inability to concentrate, paralysis of facial nerve, palpitation, dizziness, weakness of lower extremities, "heavy head," and aphasia. It should be noted that this classification represents my personal opinion, and thus constitutes a solitary exception in a report otherwise devoted entirely to factual analysis and presentation. For this reason it has been included with no little trepidation, and the cases termed incapacitating have been only those concerning which no possible doubt was entertained. It is felt, therefore, that the true incidence of incapacitating disabilities is undoubtedly considerably higher than these figures would indicate.

Incidence of Disabilities by Occupational Groups.—In addition to the occupational distribution of the survey population, Table IV also shows the incidence and rate per 100 of total disabilities and incapacitating disabilities for each of the occupational groups listed. It might be expected that the incidence rate would be higher for the more strenuous occupations, and the findings bear out this expectation to a considerable degree. In the male total disabilities the rate is highest in colliery workers, falling progressively through factory workers, other heavy labourers, "all other adults," school, and pre-school. A similar progression occurs in male incapacitating and female total disabilities with a single exception each (school and factory workers, respectively), but female incapacitating disabilities fail to provide a further parallel. The incidence percentage is higher for males than for females in both categories, but neither of these differences is statistically significant.

Conclusion

As stated in the opening sentence of this report, the survey was designed primarily to answer a single question, "Is there an appreciable incidence of persistent symptoms following cerebrospinal meningitis, and, if so, what are the nature and the severity of these symptoms?" In view of the findings, the first half of the question can be answered by an unqualified affirmative. The nature and the severity of the symptoms reported have been defined above as clearly and completely as space and the collected data would permit. Discussion has been deliberately omitted. The facts must stand on their own metaphorical feet. There are many extraneous factors other than the preceding meningitis affecting symptomatology which are next to impossible to evaluate, and this is especially true when dealing with a survey period which embraces the entire Battle of Britain with all its associated physical and psychic trauma. In view of this consideration, it seems superfluous to attempt an interpretation of these symptoms, and any such interpretation is left to the individual reader.

I wish to express my very great indebtedness to Dr. J. Greenwood Wilson, Medical Officer of Health for the City of Cardiff, and his staff; Dr. J. Emrys Harries, superintendent of the Cardiff City Isolation Hospital; Dr. T. W. Wade, medical member of the Welsh Board of Health; the superintendents of the co-operating hospitals; and the many medical officers of health and the members of their departments in the areas surveyed. My only regret is that I cannot give individual recognition to all those whose interest and co-operation made this study possible.

In recognition of his important work upon the various types of Rh factors and on their genetic transmission, the College of Physicians of Philadelphia has awarded the Alvarenga Prize for this year to Alexander S. Wiener. Dr. Wiener will give the Alvarenga Lecture before the College of Physicians of Philadelphia and the Philadelphia County Medical Society on Oct. 3, on "Rh Blood Factors in Clinical Medicine."

A REVIEW OF PSYCHOLOGICAL WORK AT THE BRAIN INJURIES UNIT, EDINBURGH, 1941–5*

BY

O. L. ZANGWILL, M.A.Camb.

Psychologist to the Department of Health for Scotland

The psychological work at the Brain Injuries Unit has developed along three principal lines. In the first place, we have given much attention to the study and assessment of specific patterns of cognitive disability associated with cerebral injury or disease. This work was inspired by urgent practical demands, but has incidentally given rise to some research studies that I shall review briefly at the end of this paper. In the second place, we have explored certain psychological techniques which may have value in neuropsychiatric diagnosis. And, in the third place, we have endeavoured to adapt, where possible, general psychological principles and methods to concrete problems of re-education and resettlement. The work as a whole has been under the general direction of Prof. D. K. Henderson and Mr. Norman Dott, the Directors of the Unit, and undertaken in close association with Dr. A. Paterson.

Problems and Methods of Assessment

I would like to preface my review of our work with some general remarks on the methods of psychological assessment and their place in clinical science. It is not uncommonly supposed that the psychologist is the fortunate possessor of an esoteric tool which in deference to current fashion I shall call the *mental test*. Now, a mental test is often conceived to measure in a more or less accurate way some specific ability, aptitude, or trait. It is apt to be regarded as the exclusive property of the psychologist, who alone is held competent to wield and interpret it. An attitude of this kind to psychological work is both unfortunate and misleading. Strictly speaking, nothing psychological is truly measurable, and a so-called mental test is nothing more than a device for eliciting some specific psychological response under controlled conditions of examination. Thus conceived, it is plain that the neurologist who examines his patient for nominal aphasia is conducting a mental test; so also is the psychiatrist who determines a patient's orientation for time or place by means of suitably chosen questions. But in cases of this kind evaluation is very easy because every normal person can be relied on to give the correct response. When we turn to functions such as memory, intelligence, and thought, and the immensely complicated repertoire of habits and skills to which they give rise in the educated individual, it is plain not only that the normal limits of individual variation are very wide but also that the potential directions of breakdown are many and varied. Simple clinical tests are in consequence seldom sufficient in assessing the psychological sequelae of cerebral lesion, and the demand for more highly controlled methods is easy to understand. Hence the appearance on the neurological scene of the academic psychologist.

In the early stages of our work I must admit that we laboured under a certain sense of false security engendered by the admitted success of standardized test techniques in assessing normal intellectual capacity. In a situation which prima facie would seem to call for the greatest caution, we psychologists showed a certain disposition to rush in where angels—and eminent neurosurgeons—rightly fear to tread. Bitter experience has since taught us to recognize that methods adapted to measure intellectual capacities in children and normal adults can seldom be applied with profit in assessing the disabilities of the neurological patient. We now appreciate that a mental test, to have genuine practical value, must be based on intimate and thorough clinical observation. My colleague Dr. Andrew Paterson has issued a timely warning in urging that premature stereotyping of methods of examination may cause us to ignore or undervalue the diverse manifestations of organic intellectual impairment that form the stock-in-trade of the clinical neuropsychiatrist (Paterson, 1944).

Before we standardize any particular test method we must make very sure that it adequately covers the clinical conditions to which it has reference. This presupposes not only an adequate clinical experience of the conditions concerned but also suitably directed experimental research. Whereas we are now beginning to gain the requisite experience, and have developed a number of more specific techniques in accordance with it, it has not as yet been possible to undertake large-scale standardization of particular procedures. Some of our most helpful tests are still rough-and-ready and are flexible enough to adapt in a provisional way to a wide range of variation both in previous level and in pattern of disability. We hope to standardize some of these tests after the war. In the meantime, we interpret them as best we can and supplement them with a number of procedures, developed elsewhere, that may happen to meet the practical demands of routine assessment. The latter include Babcock's deterioration scale (Babcock, 1930), originally devised to provide a quantitative measure of deterioration in the organic psychoses, and the Wechsler-Bellevue intelligence scale (Wechsler, 1941), both in its original form and as modified by Reynell (1944), for assessing post-traumatic intellectual loss. We have also made an eclectic use of the various types of test advocated by Goldstein to assess disorders of abstraction and conceptual thought (Goldstein, 1942; Goldstein and Scheerer, 1941; Trist and Trist, 1943). In studying more specific disabilities, especially of language, certain of the tests devised by Burt (1922), Head (1926), and Weisenburg and McBride (1935) have found application in our work. In general, although we take full advantage of existing norms for tests, we have not been chary of modifying an accepted procedure if this appears to be in the best interests of clinical expediency. What is thereby lost in statistical certainty may, it is hoped, be compensated by resulting gain in practical utility.

Cognitive Disability in Cases of Cerebral Lesion

I now pass on to review our work on assessment of intellectual disability in cases of cerebral lesion. Although it has been possible to do a certain amount of work on *acute* conditions, this in general is of research interest only (Paterson, 1942; Paterson and Zangwill, 1944a; Zangwill, 1945). The routine activity of the psychologist centres round the assessment of *residual disability*. Every patient in whom intellectual impairment is either suspected or to be excluded is referred to the psychologist for examination before discharge. But we make it a general rule that every case of this nature should first be seen by the neuropsychiatrist, who can not only advise on specific psychological investigations but also determine, where necessary, if mental testing in any form is desirable. I need not stress the pronounced catastrophic reaction to which many organic patients are prone and which in outspoken cases renders detailed testing inexpedient. In the post-traumatic conditions, likewise, admixture of psychoneurotic symptoms may render it essential that any mental testing done should be under intimate psychiatric direction. If only for these reasons, it is my firm opinion that the psychologist should invariably work in the closest association with the psychiatrist and, from the point of view of clinical management, under his personal direction. I have already indicated that my outstanding good fortune in this respect has preserved me from many of the pitfalls that beset the non-medical investigator.

The patterns of intellectual disability liable to be associated with cerebral lesions are so diverse that a comprehensive review would be out of the question. I shall therefore make no mention here of our work on the grosser syndromes recognized by clinical neurology—the aphasias, apraxias, agnosias, and disorientations—nor the well-recognized syndromes, such as confusion and dementia, which fall in the province of psychiatry. I shall also omit discussion of the conceptual disorders to which Goldstein and his school (1941, 1942) have devoted attention and which we have had occasion to study in cases with lesions of the frontal lobes. I shall confine myself to a brief selection of our findings which have had a decided practical bearing on the work of this unit.

---

* A paper read to the Society of British Neurological Surgeons in Edinburgh on June 1, 1945.

Firstly, we have been greatly struck by *the prevalence of cognitive disabilities which, in more outspoken form, are rightly ascribed to focal lesions.* In many cases, of course, the appearance of such disabilities is not surprising, as they reflect residual impairment from an appropriately localized lesion. Even so, in their reduced form of persistent defect of spelling, grammar, calculation, word choice, visual synthesis, or spatial judgment, they not uncommonly elude routine neurological examination. A more interesting finding, to which my colleague Dr. Paterson has already drawn attention (Paterson, 1944), is the prevalence of this type of disability in the clinical picture of what is usually termed generalized post-traumatic intellectual impairment. In this condition, disabilities of a relatively specific character can often be detected on careful examination and, as Paterson (1944) insists, almost certainly have localizing significance. I may add that their practical significance is often very considerable.

Secondly, we have been able to establish beyond reasonable doubt that focal disorders of visual perception, manual skill, language, and calculation, in their incipient or residual forms, commonly take the shape of what the psychologist is wont to call *decrement of special abilities.** Thus cases showing a very mild residual *dysphasic* syndrome are prone to fail rather grossly on special tests of high-grade comprehension and reasoning well within their previous grasp. This disturbance is often described by the patient himself in terms of difficulty in ordering his thoughts or in expressing himself effortlessly in an exacting discussion. Mr. Norman Dott has suggested the term "supra-dysphasia" for this condition, which warrants wider recognition. The use of special tests gives a helpful objective check on the patient's introspection, and is especially indicated in cases in which fine comprehension and formulation are of occupational relevance. We have likewise noticed that incipient or residual agnostic-apraxic disorders are almost invariably expressed on tests of intelligence stressing spatial judgment and manipulative skill. Tests of this character, often called "performance tests" (Kohs, 1927; Pintner and Paterson, 1935), appear well adapted to assess the finer grades of visual-constructive disability, and have the advantage of being thoroughly standardized in the normal. We have found them especially helpful in studying cases with lesions of the parieto-occipital region of either hemisphere, and gross deterioration of performance is not uncommon in cases which show no disturbance on the simpler tests that normally form part of the clinical examination for agnosia and apraxia. Here our field dovetails into clinical neurology. The importance of performance tests is further stressed by the fact that the majority of skilled and semi-skilled manual occupations make demands on precisely those forms of judgment and co-ordination required for proper performance in the test situation. One may add that the existence of well-circumscribed disabilities, whether of language, visual analysis, or constructive capacity, raises in an acute form the whole problem of the cerebral representation of ability, and suggests a profitable mode of attack on the cortical localization of intelligence in man.

Thirdly, we have found that *some degree of memory or learning defect is outstandingly common in cases of cerebral lesion of all types.* In the past psychologists working with neurological material have been prone to concentrate on the *deterioration* of pre-existing knowledge and capacity. While this is no doubt both interesting and important, it is often of even greater practical consequence to ascertain whether a given patient retains his old capacity to learn from experience and to acquire novel information, habits, and skills. This question arises both with reference to the re-education of specific disabilities and to the advisability of re-settling patients in an occupation necessitating special training. As Isserlin (1923) showed in the last war, the use of experimental methods of studying memory often enables us to detect a degree of impairment too slight to make itself apparent on ordinary examination but quite severe enough to constitute a real practical disability. In our own work we have not uncommonly found that a relatively severe learning defect is quite consistent with good preservation of the previous level of knowledge and ability. The learning defect in some cases appears general, affecting all spheres of psychological function (as in the Korsakov syndrome, but in much less degree). In other cases, however, especially those with focal lesions, the learning defect is often restricted to a particular performance field, such as language or spatial orientation. Here it almost certainly has localizing value, and may persist long after the grosser focal symptoms have cleared up. We have found simple learning tests (Zangwill, 1943) of decisive help in assessing memory defects, both local and general in type. Their use in post-traumatic conditions, especially, is to be advocated as a routine procedure. In this connexion I may recall that Air Vice-Marshal Symonds has commented that the post-traumatic patient not uncommonly gives the impression of being less of the man and more of the child (Symonds, 1940). Perhaps I may be allowed to add that so far as his memory is concerned he is liable to give us the complementary impression of being less of the young adult and more of the old man.

As a postscript to this review of assessment I should like to call attention to certain points of method which have special relevance to the psychological worker. In the first place one must never allow oneself to forget that *every response on a mental test must be evaluated with strict reference to the conditions under which it is elicited.* Organic symptoms at the psychological level are by no means always absolute and constant in the sense of a visual field defect or a total aphasia. Even at the level of the cerebral integration of ocular movements, Gordon Holmes (1938) and others have stressed the part played by interest and incentive in calling forth a response that cannot be elicited under the ordinary conditions of clinical examination. In ideational apraxia it is well known that the complex acts involved in purposive manipulation of objects can often be performed normally in an accustomed and properly motivated setting. It is only when the same acts are demanded under the relatively artificial conditions of examination that the patient is apt to break down and display his disability (Lange, 1936). It is therefore only to be expected that the results given on tests of the higher mental functions in the psychological laboratory will by no means necessarily give one an adequate appraisal of the patient's capability to handle comparable tasks under everyday conditions. This difficulty can never be wholly overcome in experimental psychology, and, if only for this reason, I should like to pay special tribute to Miss de Brisay and her staff of occupational therapists at this hospital, who have ungrudgingly given us the benefit of their experience and observation in arriving at a just appraisal of a patient's work capacity. But for their help much of the work undertaken in the psychological laboratory would have remained academic and sterile.

In the second place, I would like to call attention to the *variability, fluctuation, and proneness to fatigue* of brain-injury performance on sustained mental work. This was well brought out by Goldstein (1919, 1942) in his careful laboratory studies during the last war, and has again been raised by Paterson (1944) in view of our similar experience to-day. It follows that an assessment based on a single short psychological examination may give a most misleading impression of a brain-injured patient's capacity to cope with protracted work. We therefore prolong psychological observation and testing over a lengthy period—in some cases over weeks and even months—in order to reach a fair appraisal of the true level. We also check our findings at frequent intervals against the patient's work record in the occupational therapy department. In special cases we have even arranged to give a patient an extended practical trial in a line of work akin to his own and under realistic conditions. A procedure of this kind, though not always easy to arrange, can be exceptionally rewarding.

Applications to Differential Diagnosis

The experience which we have gained in delimiting the finer grades of organic intellectual impairment has proved of help from time to time in differential diagnosis of organic and psychogenic sequelae of head injury. In the field of memory impairment, for example, our work with appropriate tests

---

* The term "special ability" is used here in a general sense without specific factorial connotations. Brig. Stephenson has suggested to me that the more typical forms of circumscribed disability (verbal, spatial, etc.) might find an interpretation in terms of the factor-psychology, and Lashley (1937) has made similar suggestions in a discussion of intelligence and cerebral localization in general.

(Zangwill, 1943) has proved valuable in enabling one to distinguish with fair confidence between a true organic decrement of learning and the more capricious interference with memory so often found in the psychoneuroses. Our work in assessing milder grades of dysphasia has likewise given us some basis for evaluating non-organic disorders of language. Cases of psychogenic stammer, for instance, seldom show decrement on verbal intelligence tests, which is the rule in focal dysphasic conditions. Atypical behaviour on aphasia tests has also led us on occasion to suspect an emotional involvement which psychiatric opinion confirmed.

Among more specific psychodiagnostic methods which we have explored I shall mention only the Rorschach method (Klopfer and Kelley, 1942). Our experience with this procedure has been rather less happy than that of some of its more zealous advocates. In rare cases this method has provided important data bearing on post-traumatic deterioration or has given us evidence of an abnormal personality make-up complicating the organic reaction. In the majority of post-traumatic cases, however, the test findings have added little of real value to expert psychiatric assessment.

In the earlier stages of the war we found intelligence tests very helpful in distinguishing between deterioration and pre-existing mental deficiency. With the adoption of large-scale selection techniques, however, high-grade defectives have practically vanished from our Service material.

Re-education

I come now to the last major province of our work—namely, its bearing on re-educational procedures. Under Mr. Norman Dott's tireless enterprise the joint activities of the clinical, psychological, and auxiliary therapeutic members of the unit have reached a very high level of integrated endeavour. The psychologist's contribution can be summarized under three headings. These are, first, advice regarding re-educational procedures in patients with psychological handicaps; secondly, periodic psychometric assessment of progress made; and, thirdly, preliminary exploration of techniques which might govern re-education of special disabilities.

Advice as to method of re-education is based on careful investigation and testing in individual cases. This involves not only proper mapping-out of the major disabilities but also determination of the patient's probable capacity to profit from training in the various performance fields affected. The choice of any particular method of re-training is governed both by general principles, in particular those laid down by Goldstein (1919, 1942), and by the balance of findings in the individual case. *Direct* re-training, in which the lost function is built up anew by tuition and exercise, is indicated especially in the expressive speech disorders. *Indirect* training, making play with what have been called substitution and detour methods, is generally called for in cases with receptive language disorders, especially reading. The particular programme of re-education in any given case will thus depend very largely on the individual patient and the balance of ability and disability which he presents.

Assessment of progress in patients undergoing prolonged re-education on account of psychological disabilities is undertaken every two or three weeks. In a considerable number of cases, for the most part aphasics undergoing prolonged speech therapy, we have been able to obtain detailed records of progress during the whole course of rehabilitation. Evaluation of this material is helping us to arrive at conclusions bearing on the types of aphasic syndrome which yield most adequately to re-education and the optimal length of treatment indicated.

We have undertaken some experimental studies of re-education methods with especial reference to reading, writing, and calculation. This work has been done with the active collaboration in the first place of Mrs. H. Mitcheltree, formerly speech therapist to this hospital, and more recently of Miss E. Butfield, my present colleague in the unit. We have devoted considerable attention to re-training alexic patients on the compensatory basis of kinaesthesia and touch, in some cases with conspicuous success. We have also made special investigations of acalculia with a view to improved re-educational procedures. Here, too, our tentative methods have met with limited success. Another field to which we have devoted study is the *re-education of brain-injured children*. Here the position is complicated by the fact that we have to consider not only the re-education of what has been lost but the educational prognosis. Intensive study associated with practical educational work has in some cases enabled us to advise both parents and teachers as to educational management of children with residual dysphasia and other types of scholastic handicap. This field obviously calls for development, but careful follow-up studies will be needed before general conclusions can be drawn.

Rehabilitation

The results of psychological examination have not infrequently been of help in formulating a general course of rehabilitation and occupational therapy. Thus timely recognition of high-grade defects such as colour agnosia, impaired spatial judgment, and constructive apraxia has on occasion helped to guide Miss de Brisay and her staff in fitting the most adequate available course of occupational therapy to the individual patient. Reciprocally, the therapists' observations have not uncommonly called our attention to special disabilities displayed in a practical setting and suggested more intensive laboratory investigation.

Disposal and Resettlement

The psychologist has sometimes been in the position to contribute to practical problems of disposal and resettlement by placing his observations in the hands of those called upon to assess an individual case and advise as to his future. In some cases our observations, when taken together with work records in the occupational therapy department, have provided material of direct relevance both to optimal disposal and to proper assessment of compensation and pension claims.

Fundamental Research

The material at the Brain Injuries Unit has proved a veritable gold-mine from the point of view of research on fundamental psychological problems. Owing to war conditions and practical exigencies it has not as yet been possible to communicate all of our material, but I may mention some work on orientation in the confusional state that it has been my privilege to undertake in collaboration with Dr. Andrew Paterson (Paterson and Zangwill, 1944a) and a joint communication from us on visual agnosia and disorientation associated with lesions of the non-dominant hemisphere (Paterson and Zangwill, 1944b). On the more specifically psychological side, I may mention a preliminary report on clinical tests of memory impairment (Zangwill, 1943) and some observations on the Rorschach test in cases of acute head injury (Zangwill, 1945). It is hoped to communicate further research studies shortly.

Conclusions

The main directions of psychological work undertaken in this unit during the past four years have been outlined. These include studies and assessment of high-grade intellectual defects, explorations of adjuvant techniques in neuropsychiatric diagnosis, and practical contributions to re-education, disposal and resettlement. Some contributions to psychological research are also reviewed.

I wish to thank Prof. D. K. Henderson and Mr. Norman Dott, the Directors of the Brain Injuries Unit, for their invaluable guidance, encouragement, and help; and Dr. Wm. McAlister, medical superintendent of this hospital, for his kind permission to study the case material. In its research aspects this work has been made possible by the support of the Rockefeller Foundation.

ACCIDENTAL INFANT SUFFOCATION

BY

W. H. DAVISON, M.B., D.P.H., Barrister-at-Law
H.M. Coroner, Birmingham

No special study of the true incidence of infant suffocation appears to have been made in this country or the U.S.A. (see *B.M.J.*, 1945, 1, 524). The information necessary for an analysis is not available to the investigator except through the coroner, and then only by his closest co-operation, and as over 70% of coroners have no medical qualifications their interest is mainly confined to the purely legal aspect of each case. Further, the coroner's procedure precludes to a large extent the collection of comprehensive data by anyone but that official himself.

In England and Wales cases of death of infants from suspected suffocation are reported to the coroner of the district, either directly or indirectly, by the doctor called in to examine the child at death. If the doctor issues a death certificate certifying the cause of death as asphyxia or suffocation the case reaches the coroner through the Registrar of Births and Deaths under Statutory Rules and Orders, 1927, No. 485, thus ensuring that it does not escape investigation. It may be that a coroner will act on the strength of the doctor's opinion as to the cause of death without necessarily having the confirmation of a post-mortem examination. Prior to 1927 this was usually the case, as it was then not possible for a coroner to order a post-mortem examination without holding an inquest; therefore the medical opinion as to the cause of death, based on circumstantial evidence and external examination only, was usually accepted. The Coroners' (Amendment) Act, 1926, however, gave the coroner authority to order a post-mortem examination without necessarily committing the case to an inquest if death was found to be due to natural causes. Since that date every death in Birmingham from suspected suffocation of an infant dying in bed with its parents or others, or found dead in a cot, has been the subject of a post-mortem examination conducted by a skilled pathologist. It will be appreciated that all these deaths were entirely unexpected and that no doctor had recently been in medical attendance upon the child during life. The result of this altered procedure is reflected in the statistics in the following manner.

Birmingham Statistics

During the seven years 1938 to 1944 the total number of deaths reported to me of which asphyxia was considered as a possible cause was 318. Of these, 108 occurred while the infant was in bed with its parent or other person, and as a result of post-mortem examinations only 18 of these 108 were shown to have died from asphyxia occurring mechanically. It is also significant that of the remaining 210 cases in which an infant died while sleeping alone in a bed, cot, or perambulator, post-mortem examination established mechanical suffocation as being the definite cause of death in only 6 cases. Of the deaths 280 were due to natural causes, 152 to respiratory infection alone, and 77 to a respiratory condition associated with otitis media. Table I sets out in detail the age distribution and causes of death in the 318 cases as determined by the post-mortem examination.

Available statistics show that the total number of deaths attributed to asphyxia while in bed with parents or other persons in the Birmingham coroner's area during the seven years 1918 to 1924 was 130 when the estimated population was 550,000, as compared with 18 occurring during the seven years 1938 to 1944 with an estimated population of 1,000,000.

All the post-mortem examinations were conducted by skilled pathologists, including Prof. G. Haswell Wilson, professor of pathology, University of Birmingham; Prof. J. M. Webster, director of the West Midland Forensic Science Laboratory; Dr. J. M. Smellie and Dr. W. Carey Smallwood, honorary physicians and clinical pathologists on the staff of the Birmingham Children's Hospital; also the pathologists of the Children's and the Maternity Hospitals, Birmingham, and others.

Table I.—*Causes of Death (1938-44)*

Age	No. of Deaths of Children, occurring in Bed with one or more other Persons, for which Asphyxia was considered a possible cause	No. of Deaths of Children, occurring while alone in Bed, Cot, Perambulator, or other form of Improvised Cot, of which Asphyxia was considered a possible cause	Asphyxia occurring by Mechanical Means while in Bed with Parents or other Person	Asphyxia occurring by Mechanical Means while in Bed, Cot, Perambulator, or other form of Improvised Cot, alone	Asphyxia, cause of which was not definitely established—i.e., by Mechanical Means or Natural Causes	Asphyxia due to Inspiration of Vomit	Bronchopneumonia, Capillary Bronchitis, Bronchiolitis, without Complications	Bronchopneumonia or Respiratory Disease with Otitis Media	Bronchopneumonia or other Respiratory Disease with Contributory Cause—i.e., Pyelitis, Toxic Hepatitis	Otitis Media and Mastoiditis	Disease of Larynx	Neonatal Intracranial Haemorrhage	Meningitis	Tracheitis with Infection in Liver and Spleen	Congenital Atelectasis with Enlarged Thymus	Tonsillitis	Status Lymphaticus	Enteritis	Congenital Heart Disease	Atelectasis	Birth Injury	Convulsion—no Apparent Reason	Encephalitis	Immaturity

The findings as shown justify me in stating as my considered opinion that all deaths from suspected accidental infant suffocation should be the subject of post-mortem examinations, both from the point of view of correct statistical information and in some cases to relieve the mother from mental torture or reproach. Despite their grief, the relief of parents is often very apparent when informed that the death was due to circumstances beyond their control. Careful inquiries made in every case have revealed that there was a complete absence of prodromal symptoms or any departure from the normal sufficient to justify the parent in seeking medical advice—in other words, death was entirely unexpected, even in those cases in which the cause of death was found to be respiratory or due to otitis media. It would appear that an infant could develop bronchopneumonia or capillary bronchitis without complications, or even accompanied by otitis media, and die suddenly without warning, as is shown by a considerable number of the 229 deaths from these causes.

Quite a number of the children in all groups were found prone or with the face turned into the pillow—borne out by post-mortem hypostasis—suggesting death from obstruction to the air passages; and in the absence of other factors one might naturally conclude that death was caused by mechanical means.

In the 11 cases of death from inspiration of vomit, inquiry into the circumstances of how and when the child was fed did not seem to have any direct bearing on the death.

The total numbers of deaths due to mechanical suffocation in bed, cot, or cradle, etc., in England and Wales, taken from the Registrar-General's Returns, for the years 1940, 1941, and 1942, were 308, 379, and 358, respectively (*B.M.J.*, 1945, **1**, 602). If the Birmingham figures are any guide, in view of the fact that the population is approximately one-fortieth of that of the country, it would appear that these figures are much too high, and that they would be corrected by the universal procedure of post-mortem examination.

My experience is that doctors who, at the time of reporting a death, honestly believed that a child had been suffocated by mechanical means have frequently expressed their surprise on attending the post-mortem examination, which showed that death was not due to these causes but to other factors. Consequently, I consider that every medical practitioner should act warily in such cases, and should so qualify his opinion as to the cause of death as to necessitate the coroner concerned using his powers to obtain the best opinion possible, by means of a post-mortem examination.

It will be observed from Table I that all cases of children asphyxiated while in bed with the parents occurred during the first four months, and that all cases of asphyxia by mechanical means occurred during the first seven months of life. Seasonal incidence in deaths from respiratory infections and mechanical asphyxia is shown in Table II. Annual deaths from suffocation while in bed with parents or others occurring in Birmingham from 1916 onwards are shown in the accompanying chart.

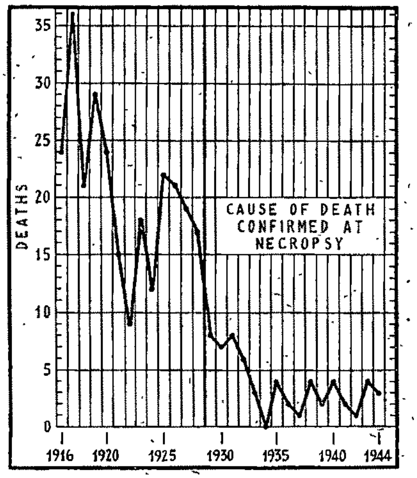

Chart showing annual deaths from mechanical suffocation while in bed with parents, or others, in Birmingham from 1916 to 1944.

TABLE II.—*Seasonal Incidence, 1938–44 (7 years)*

Asphyxia while sleeping alone	—	2	—	—	—	—	—	—	2	—	1	1	6

Summary

Attention is drawn to the fact that statistics relating to infant suffocation are misleading and err on the side of over-estimation. Circumstantial evidence that suffocation was the cause of death is not sufficient.

Accurate information regarding the true position in a city of 1,000,000 inhabitants revealed an incidence very much lower than is generally accepted.

During the years 1938 to 1944, of 318 deaths considered as possibly due to asphyxia only 38 were shown to have been so caused; 18 of these resulted from mechanical suffocation while in bed with some other person, and 6 from mechanical suffocation while sleeping alone. The remaining 280 deaths were definitely ascribed to natural causes, principally bronchopneumonia, often with an associated otitis media.

A post-mortem examination is indispensable as part of the routine investigation in every case where suffocation is considered a likely cause of death. Evidence in support of this is furnished by the Birmingham deaths, which show such a pronounced fall from 1929 onwards, when this procedure was adopted.

The number of deaths in infants reported to the coroner during the past three decades shows a very marked and progressive fall. This is undoubtedly due to many factors, including improved social and housing conditions, and the activities of the child welfare section of the public health authorities; but in the group in which death was the result of mechanical suffocation I feel that the present statistics for the whole country do not do justice to the real improvement that has taken place in recent years.

The remedy rests in the first instance with the medical practitioner, and, failing him, with the coroner.

POLYNEURITIS AFTER JUNGLE SORES

A SERIES OF TWENTY-ONE CASES

BY

R. L. WARD, M.B., B.S.Lond.
Capt., R.A.M.C.

AND

A. S. MASON, M.B., B.Ch.
Capt., R.A.M.C.

In a recent campaign in the Burmese jungle British and Indian troops were fighting for upwards of five months under appalling geographical and climatic conditions. During the operation many of these men developed multiple indolent ulcers, mainly on their limbs, and commonly known as "jungle sores." It was noticed that several of those who had suffered from jungle sores contracted a peripheral neuritis later. This paper describes a series of such cases. Owing to war conditions it has been impossible to make satisfactory laboratory investigations; for the same reason the literature on the subject was not available. Therefore this description must be considered from the purely clinical standpoint.

Clinical Data

Twenty-one cases of peripheral neuritis were seen in hospital. Of these, 11 were admitted complaining of symptoms referable to their neuritis; nine because of malarial relapse, and one with jungle sores. All of them had suffered from jungle sores, but, except for Case 19, the ulcers were healed at the time of admission. The number of ulcers on each man varied from 2 to 40, with an average of 14. The commonest sites were the lower leg and forearm. Ulcer scars were also found on the wrists, ankles, arms, buttocks, and shoulders, in that order of frequency. The average healing time was 8 weeks, but varied from 4 to 17. The description of the jungle sores as given by the patients in no way differed from the unhealed sores seen by us. A typical one was about ¾ in. in diameter, circular or oval in shape. It presented a punched-out appearance, with a necrotic sloughing base and unhealthy purple edges; but the local reaction was slight, and was confined to the margins of the ulcer.

The clinical course of all cases in the series was remarkably constant, and the sequence was as follows. In 16 cases the first symptom of nervous involvement was blurring of vision, the common complaint being that after reading two or three pages the print became blurred and reading was impossible. This symptom was usually noticed about seven weeks after the jungle sores began. The earliest it appeared was in four weeks and the latest 12. The average duration of blurred vision was four weeks, the eyesight returning to normal after this time. In all patients there was disturbance of sensation. In four cases it synchronized with blurring of vision, but in the remainder it occurred three weeks later. The average time between the onset of jungle sores and the appearance of sensory disturbance was 10 weeks. Sensory symptoms, consisting of tingling, numbness, and coldness of the extremities, were often severe enough to make the men report sick. In the milder cases these paraesthesiae were the only complaints; however, others later complained of difficulty in walking and writing. The picture in its most sevre form was completed by progressive weakness of the limbs spreading to involve hips and shoulders.

In addition anaesthesia of the extremities, astereognosis, and ataxia were present. From a shuffling walk with feet apart the gait deteriorated until walking was impossible.

Examination of the nervous system in these cases showed the characteristic signs of a polyneuritis. In addition to this, paralysis of accommodation was a marked feature of the disease. However, in the few cases in which eyesight was blurred during stay in hospital the pupils reacted to light and to accommodation. The phenomenon was subjective, and was shown by defective near vision. There was paresis of a lower motor neurone type, peripheral in distribution; maximum weakness being in the hands and feet. The weakness spread centripetally, but recovery took place in the reverse direction. Loss of power was more pronounced in the extensor than in the flexor muscle groups; although characteristically bilateral, it often predominated on one side. The distribution of the paresis in no way followed that of the jungle sores. Impairment of sensation followed the distribution of the paresis, all forms being affected, including postural sense. In the severe cases astereognosis and ataxia were present. Increased muscular tenderness was rare. Vasomotor disturbances were seen in a few cases, as evidenced by blueness and coldness of the extremities. It was observed that the area affected by paraesthesiae was larger than that of actual anaesthesia. Tendon reflexes of the affected limb were either absent on admission or rapidly disappeared. Even when there was minor disturbance of motor and sensory function the corresponding reflex was absent or sluggish. Muscle tone was normal in all cases and wasting of muscles did not occur. Except for these findings in the C.N.S., physical examination was negative. The cases fell into the age group 20–30. The general condition of all was good. No anaemia, glossitis, or malnutrition was observed. Clinically there was no cardiac abnormality and the pulse was normal in rate and rhythm. The gastro-intestinal tract was also normal.

Mild Cases

The cases may be classified according to the severity of their disability. Eleven were classified as mild—i.e., disability unnoticed except when attempting physical exertion. A typical example of this group was Case 8.

Case 8.—Admitted to hospital for malaria. Also complained of tingling and numbness of hands and feet. Stated that he found it difficult to march more than a mile. Jungle sores began in Burma, followed 8 weeks later by blurring of vision. Four weeks later the paraesthesiae started and the jungle sores healed. No history of diarrhoea. On examination, nutrition good. No evidence of avitaminosis or anaemia. Scars of healed jungle sores on legs. All systems except C.N.S. normal. C.N.S. examination: pupils regular, equal, reacted to light and accommodation; all cranial nerves normal; bilateral weakness of grip and dorsiflexion and plantar flexion of feet; no other muscular weakness; no disturbance of muscle tone; slight impairment of all forms of sensation over both feet; postural sense slightly impaired; ankle- and knee-jerks absent bilaterally; all other reflexes present. Gait fair while wearing light shoes; with boots, dragging of toes and walking with feet abnormally wide apart, this being accentuated when the eyes were closed. In two weeks paraesthesiae had disappeared. In three weeks power was returning to normal, and the patient was discharged from hospital, knee- and ankle-jerks still being absent.

(a) Time of onset reckoned from beginning of jungle sores.
(b) + = Weakness of grip/foot.
++ = Weakness up to and including forearm/leg.
+++ = Weakness up to and including upper arm/thigh.
++++ = Weakness up to and including shoulder/buttock.

(c) 1 = Disability only on exertion.
2 = Routine life impeded.
3 = Bed-ridden.

Moderately Severe Cases

In seven cases, classed as moderately severe, the disability was sufficient to impede the patient's everyday life. Case 1 is an example.

Case 1.—Admitted for symptoms referable to polyneuritis. Nineteen weeks before admission jungle sores started, and 12 weeks later he noticed blurring of vision. Three weeks before admission, onset of increasingly severe tingling in hands and forearms. Simultaneously walking became difficult. Weakness was progressive, until on the date of admission he could scarcely walk. Fine movements of hands were clumsy. Abnormal physical signs: Pronounced bilateral weakness of grip and forearms; moderate weakness of upper arms; marked weakness of feet, legs, and thighs; some degree of left foot-drop; in all limbs extensor muscle groups were weaker than the flexor; partial anaesthesia of "glove-and-stocking" type bilaterally; postural sense very poor; astereognosis and ataxia marked. All tendon reflexes absent. Progress: Power returned steadily; in two weeks foot-drop disappeared. After three weeks fine movements of hands became possible and anaesthesia was absent. Patient was discharged after six weeks; shortly beforehand paraesthesiae had gone, but although power greatly improved, it would not permit severe exertion.

Severe Cases

Of the series only three cases became bed-ridden; one of these is described.

Case 12.—Gave a history of jungle sores beginning two months previously; finally healed a few days before admission. Present complaints: tingling of extremities, unsteadiness of gait, and blurring of vision. These occurred at approximately the same time as the sores healed. On examination, general condition good. No evidence of avitaminosis or anaemia. Scars of healed jungle sores on legs and forearms. All systems normal except C.N.S. C.N.S. examination: pupils and cranial nerves normal; weakness of grip—L. > R.; slight weakness of extensors of wrist and dorsiflexors of ankle; no anaesthesia; upper-limb tendon reflexes present; ankle- and knee-jerks absent on both sides. Two days after admission:—Tendency to foot-drop, L.>R.; impairment of all forms of sensation up to knees; astereognosis present; biceps jerks now absent. There followed a rapid increase in weakness, maximal peripherally and spreading towards the trunk. Ten days after admission:—Patient unable to move either arms or legs; muscles of both hips and shoulders weak; sensation bilaterally impaired up to the elbows, and on legs up to and including the perineum; no disturbance of sphincters; all tendon reflexes absent; cremasteric and abdominal reflexes present. One month after admission:—First signs of recovery appeared; power of hips and shoulders began to return. Six weeks after admission:—Able to lift arms above head; power returning to upper arms and thighs; foot-drop improved; area of anaesthesia greatly diminished. Eight weeks after admission:—Able to use hands and stand with support; extremities still weak and with impaired sensation; all tendon reflexes absent. The paraesthesiae, which had disappeared at the time of maximum anaesthesia and had returned in the early stages of recovery, now left him entirely. At this point the patient was transferred to a rehabilitation centre.

Discussion

There is no doubt that these patients were suffering from a polyneuritis, the aetiology of the condition being the main point of interest. Chemical poisons such as arsenic can be excluded as the aetiological agent, since no patient gave a history of exposure to this. Acute infective polyneuritis is excluded on the natural history of the disease, the onset in the series being insidious and the course afebrile. It remains to decide whether the polyneuritis is the result of a vitamin deficiency or is due to a bacterial toxin. Cases of vitamin B deficiency were seen in troops engaged in the same operation; the picture presented by these was primarily one of wasting and diarrhoea, with glossitis. Polyneuritis, when present, was mild and responded quickly to intensive vitamin therapy.

In the cases under discussion the polyneuritis, as has been shown, could be completely disabling, and was not influenced by adequate doses of the vitamin B complex. Moreover, the nutrition of all cases was good, despite the conditions under which they had been living, no glossitis and no diarrhoea being noticed.

Since a constant association between jungle sores and a subsequent polyneuritis was noticed, it is likely that a toxin, elaborated by bacteria infecting these ulcers, was the responsible agent. Clinically a marked similarity exists between jungle sores and the desert sores seen in troops of the M.E.F. It was found that a number of desert sores were infected with diphtheria bacilli; similarly these organisms have been isolated from jungle sores. In our series of polyneuritic cases, except for one patient, the sores were healed at the time of admission. From the unhealed sores of this case (No. 19) diphtheria bacilli were isolated. However, a week after admission this patient developed faucial diphtheria; therefore it is difficult to decide whether the polyneuritis was due to the faucial or to the extrafaucial infection.

The time of onset of polyneuritis indicated the latter. The outstanding clinical point in favour of a diphtheritic aetiology is the paralysis of accommodation noted in a large percentage of cases. It is also important to note that the neuritis was not locally related to those areas affected by jungle sores. In a few cases neuritis of the legs and arms followed when the ulcers had been present only on the arms, and vice versa. The loss of accommodation can also be explained by assuming a blood-borne spread of the toxin. This form of generalized peripheral neuritis is seen in both faucial and extrafaucial diphtheria, and as a clinical entity differs from other types of polyneuritis. The number of ulcers did not influence the severity of the disease; similarly, neither did the duration of unhealed jungle sores. A feature of interest was the fact that although Indian troops taking part in the same operation developed jungle sores, no case of a subsequent polyneuritis was discovered. It is well known that diphtheritic infection is rare in Indians.

From the above facts it is felt that all the cases represent a polyneuritis of diphtheritic origin. The value of Schick testing was obvious, but although every attempt was made to obtain the toxin none was available. Electrocardiographic studies would also have been valuable. The origin of a diphtheritic infection incurred in the jungle is obscure. These cases of polyneuritis were drawn from all the units concerned in the operation. If a carrier was the source of infection it is likely that the cases would have been grouped in one unit. All troops came into contact with the native population, and it is more likely that the infection was introduced from them. However, no details are known of the incidence or carrier rate of diphtheria in the Burmese.

From a military point of view this disease can cause a serious wastage of man-power. Even the mild cases will be unfit for jungle warfare for six months from the onset of their disability. The severe cases will probably take a year to recover fully. These men neither had been immunized against diphtheria nor had previously suffered from the disease. If the diphtheritic origin of this polyneuritis is accepted the question of prophylactic immunization will arise for troops engaged in future jungle operations.

Summary

Twenty-one cases of polyneuritis subsequent to jungle sores are described.

The course of the disease followed a constant pattern.

Sixteen out of 21 cases had loss of accommodation.

In reviewing the aetiology it was considered most likely that the polyneuritis followed a diphtheritic infection of the jungle sores.

We wish to thank Col. Wm. Morrison, *M.C.*, F.R.C.S.Ed., officer commanding a general hospital, for his advice and friendly criticism, and also for permission to publish this article.

ACUTE INFECTIVE POLYNEURITIS

BY

C. P. PETCH, M.B., M.R.C.P.

A./Squad. Ldr. R.A.F.V.R.; Medical Specialist

A form of acute polyneuritis apparently of infective origin is well recognized by neurologists but has received little attention in English medical textbooks. It is probably more common than polyneuritis due to the classical toxins, and seems often to be a source of diagnostic confusion. The following case, which appears to be typical, seems therefore worth recording.

Case Report

An air-gunner aged 23 was admitted to his station sick-quarters with a left facial palsy. On the day of admission he rapidly developed "pins and needles" in arms and legs, with marked muscular weakness. The condition was recognized as a generalized one, and he was transferred to hospital. There was no sphincter disturbance. On admission to hospital it was elicited that he had had a bad cold and chill a fortnight previously. Apart from appendicectomy a year ago, he had always been healthy and never a heavy drinker. On examination he was afebrile, but appeared ill. A complete left facial palsy of the lower motor neurone type was present, but the other cranial nerves were normal. The fundus oculi was healthy. There was marked muscular weakness of arms and legs, with winging of the right scapula. The proximal muscle groups, indeed, were particularly affected. Tendon reflexes could still be obtained on admission, but within a few days had entirely disappeared from the legs and left arm, and were feeble in the right arm. The muscles were flaccid and toneless. The upper abdominal reflexes were present, but not the lower; the plantars were flexor. No reliable sensory changes could be discovered, but the paraesthesiae were the cause of much complaint. The throat was clear, the nose a little congested. No K.L.B. could be isolated from a swab. Other systems were normal. Lumbar puncture on the day after admission showed a clear fluid under normal pressure, with no cells; protein, 45 mg. per 100 c.cm.; Wassermann reaction negative. Recovery from the facial palsy was rapid, being complete within a month. In the arms it was slower, but tendon reflexes were present in three weeks and normal in four. The legs were slowest of all, and convalescence was attended by much aching in the feet. After nine weeks the lower-limb reflexes could be obtained, with the exception of the left ankle-jerk. By 11 weeks he was walking well with the aid of a stick, and shortly afterwards was transferred for rehabilitation. All tendon reflexes had returned by this time, but there was residual weakness of the glutei and calf muscles, with still a little pain in the feet.

Discussion

A description of this condition, with post-mortem findings, was given by Gordon Holmes (1917) under Osler's diagnosis of acute febrile polyneuritis. A more detailed account, based on 30 cases, was published by Bradford, Bashford, and Wilson (1919). Transmission of the disease to monkeys from post-mortem material is described and its infectious origin held to be established. Hence the term "acute infective polyneuritis," which has since been commonly used. In the present war a group of 7 cases has been described by Barber (1940) under the title "Polyradiculoneuritis (Guillain-Barré Syndrome)," which he gives reasons for considering the same as Holmes's. From the descriptions this would appear reasonable, though Guillain (1936), writing 20 years after his original publication, still wished to draw a distinction between the syndrome known by his name and the type characterized by fever. The eponym, much used by French writers, pays tribute to his work on the subject. American authors have added other series in recent years. Forster, Brown, and Merritt (1941) describe 26 similar cases as "polyneuritis with facial diplegia," although facial involvement was not a constant feature, being lacking in four patients. They point out incidentally that their cases showed a much worse prognosis than is usually given, 11 ending fatally, and suggest that an increase in virulence of the hypothetical causative virus occurred at one period of their survey. An interesting possibility that has often been discussed is that Landry's paralysis is a form of the disease under consideration (Pinckney, 1936; Garvey and Slavin, 1938). A long list of synonyms is given in the recent editions of Osler's *Medicine.*

The importance of establishing the diagnosis is not entirely academic, in spite of our ignorance of the aetiology and the specific therapy. Cases are often labelled anterior poliomyelitis, and a much more serious prognosis given as regards paralysis than is warranted. On the other hand, failure to appreciate the possibility of involvement of the respiratory muscles may assist in fatal consequences. Points of differential diagnosis in poliomyelitis are given by Gordon Holmes as "the more rapid evolution and the more irregular distribution of the palsy, the frequent paralysis of the trunk muscles, and the usual absence of objective sensory symptoms in this disease." It is also generally agreed that in the polyneuritis there is usually a considerable interval between the febrile episode, which may mark the onset of the illness, and the appearance of the characteristic symptoms. Recovery, too, tends to be complete. The C.S.F. findings show in polyneuritis an increase of cells—an acellular albuminosis, as it has been called. This was not marked in the present case, but the sample was obtained very early. I have usually noted higher figures for protein in civilian cases, which come to hospital at a later stage of the disease. On the other hand, seven of Forster, Brown, and Merritt's cases had protein within normal limits, and they find that this cannot be explained on a time basis.

This case was apparently a sporadic one, and no evidence of a local epidemic has been found.

My thanks are due to the Air Ministry for permission to submit this note.

Medical Memoranda

Misleading Evidence in Establishing the Time of Death

The rate of emptying of the stomach is considered a useful if subsidiary means of establishing the time of death in medico-legal cases. The following case presents unusual features in this connexion.

CASE RECORD

The dead body of a soldier aged 26 was admitted to the mortuary of a military hospital in the M.E.F. He had sustained severe head injuries when the truck which he was driving overturned, and he died 13 minutes later without recovering consciousness. The body was placed in the mortuary refrigerator 4 hours after death, and the necropsy was performed 14 hours later.

The face and forehead were gashed and abraded, and the left maxilla driven backwards, with depression of the floor of the left orbit, indicating a severe blow on the face. The skull was widely comminuted and the undersurface of the brain lacerated. On section, the mid-brain was peppered with small perivascular haemorrhages and the ventricular fluid was heavily blood-stained. The lungs contained a quantity of blood inhaled from the nasopharynx. A small tear was found in the liver, and the pelvis was fractured.

The stomach was empty; but, lying free in the jejunum, 12 inches below the duodeno-jejunal flexure, was a vulcanite denture with 8 jagged points round the convex border, and bearing one artificial tooth. Its shape was roughly triangular, the base 38 mm., the altitude 25 mm., and it was curved to fit the hard palate. Passage of the denture appeared to have caused no injury to the food channels.

COMMENT

Subsequent interrogation of a companion in the truck disposed of the idea that the deceased had swallowed his denture before the accident, and it is reasonably certain that it was dislodged at the time of the facial injury. It would appear that the denture had then been swallowed while the patient was unconscious, and passed through the oesophagus, stomach, and duodenum into the jejunum, travelling 45 inches from its original position in the mouth in the course of 13 minutes.

Sydney Smith in his *Forensic Medicine* states that after a full meal food begins to leave the stomach in 15 minutes, and that the stomach is empty in 2 to 5 hours; that a barium meal passes through the stomach almost at once, but that metallic foreign bodies may be retained in the stomach for days; and that food travels through the small intestine at the rate of about 6 feet in an hour.

The surprising distance travelled by the denture may have been due to accelerated peristalsis during life or persistent peristalsis after death; but, in either case, had the time of death been unknown the evidence of the denture would have proved misleading.

Scabies and D.D.T.

The success of D.D.T. in preventing infection by lice has caused many people to wonder whether it has any effect on scabies. There is little information about this. Buxton (1945) in his excellent account of D.D.T. does not mention scabies, but in the discussion of his paper K. Mellanby says—"D.D.T. is certainly not to be recommended for the treatment of scabies." To determine whether D.D.T. has any prophylactic action against scabies, I examined, in conjunction with Major G. A. Hodgson, a series of infected soldiers to see how many had been wearing impregnated shirts or had been using D.D.T. powder regularly and recently; "recently" was interpreted as being within the last two months. We obtained the following results:

	Scabies Patients			Controls		
	Cases	Yes	No	Cases	Yes	No
G. A. H. ..	48	23 (48%)	25 (52%)	111	46 (41%)	65 (59%)
F. F. H. ..	52	29 (56%)	23 (44%)	100	64	36
Total ..	100	52%	48%	211	110 (52·2%)	101 (47·8%)

("Yes" signifies wearing an impregnated shirt and/or having used D.D.T. powder regularly within the last two months.)

The difference between the proportions protected in the two series is due to their having been observed, purposely, in two different areas. The almost exact identity between the scabies patients and the controls shows that D.D.T. has no preventive action against the acquirement of scabies.

A Method of End-to-end Anastomosis in the Small Intestine

In lesions of the small intestine requiring resection speed is of very considerable importance in war surgery, and side-to-side anastomosis is therefore seldom done because, while giving a very satisfactory union, it is undoubtedly time-consuming. The common method of end-to-end anastomosis is to unite the cut ends with two layers of sutures—an inner "all-coat" and an outer "sero-muscular"—but this method has two disadvantages. In the first place it is often found that closure of the mesenteric angle gives rise to some difficulty, and at the end of this part of the anastomosis there is sometimes a feeling that one's technique at this stage has not been quite up to standard. Indeed, this fact has lately been uncomfortably proved at the necropsy of a patient dying of paralytic ileus from peritonitis, where a small localized abscess was found within the mesenteric angle. The second disadvantage is that the two layers of sutures produce a thick and rigid anastomotic line predisposing to mechanical obstruction.

The following method of anastomosis has been devised to overcome these difficulties and to reduce the operative time. The diagrams explain the stages of the operation.

METHOD

Having determined the line of bowel resection, the mesentery of the efferent loop is divided at this level, but with the afferent loop the mesentery is divided 1 in. proximal to this line, thus leaving 1 in. of bowel without mesenteric attachment (Fig. 1). Next, three catgut (00) sutures are introduced from without inwards into the efferent gut. These sutures are inserted 1 in. distal to the line of resection and are placed equidistantly around the circumference of the gut, with one suture at the antimesenteric border. Each stitch is then brought out through the end of the efferent loop; the corresponding part of the end of the afferent loop is picked up, and the stitch returns within the lumen of the efferent loop again, to emerge close beside its point of entry, where the ends are tied (Figs. 2 and 3). Thus the afferent loop is invaginated within the efferent loop and the cut ends of the mesentery are now in apposition. A continuous suture, picking up all coats of the cut end of the efferent loop, and the sero-muscular coats of the afferent loop at the level of mesenteric attachment, now completes the anastomosis, and the mesenteries are united by interrupted stitches (Fig. 4).

COMMENT

The advantages of this method are that it is quick and easy to perform and makes leakage at the mesenteric angle impossible. In addition it is felt that it offers less resistance to normal peristaltic movements along the gut.

Two criticisms may be anticipated: (1) Bleeding at the cut end of the afferent loop has not been controlled. In practice, noticeable bleeding has not occurred here, probably because of the distance below the mesenteric attachment at which the gut is divided. (2) The passage of the three interrupted sutures within the lumen of the gut might be considered to spread infection. This obviously is of no importance in war surgery, where gross soiling is inevitably present; and even for "clean" resections this soiling can be of little importance until we more nearly approach the ultimate goal of aseptic anastomosis.

Excluding patients who have died within 24 hours of operation from the severity of their wounds, this method has now been employed in 6 cases, 5 of whom survived. The one death occurred on the 4th post-operative day from gas gangrene of the abdominal wall, and necropsy showed no intraperitoneal trouble and a sound anastomosis.

Access to the literature is impossible at present, but it is felt that an operation of this type has possibly been described before. Personal ignorance of the existence of such a technique has, however, prompted the description of this method of anastomosis.

Major, R.A.M.C.

Two Cases of Air Embolism

In view of recent references to air embolism the following two cases may be of interest.

CASE I

Mrs. L., aged 30, suffering from tuberculous infiltration of the right apex. Left lung healthy. Has had an artificial pneumothorax since March, 1944. Collapse satisfactory and well maintained; patient making good general progress.

After screening, a refill was thought necessary, and at 11 o'clock one morning a needle was inserted in the fifth intercostal space in the anterior axillary line, as was customary with this patient. Pressure was −2, −4 and manometer movement was sluggish; a probe was used to make sure that the needle was clear, but readings persisted. A little air, less than 50 c.cm., was blown through to clear the needle. Patient remarked, "Something funny is happening, Doctor. I think I am going to faint." The needle was withdrawn forthwith. Mrs. L. then became unconscious with eyes wide open and stertorous breathing. Pupils were widely dilated; pulse almost imperceptible though colour remained good. A fine tremor was present throughout the whole body. About ten minutes later the pulse was quite imperceptible and paresis of the left side of the face was noticed. Two c.cm. of nikethamide solution was given intravenously. Dilatation of pupils decreased somewhat, the eyes closed and resisted opening; conjunctival reflex present. Tremor had ceased. The patient was put to bed between two hot blankets and with numerous hot-water bottles. About an hour and a half later she showed signs of returning consciousness and drank a few mouthfuls of tea. She relapsed again, and at 4.30 p.m. there was another fit of trembling with marked photophobia. A quarter of a grain of morphine was given. At 6 p.m. patient was conscious and rational but complained of severe post-orbital and frontal headache. She said that she was blind and could see nothing but a white sheet. Pupils were half dilated and she was obviously unable to see.

Twelve hours later, after a restful night, patient felt well and her vision had improved to the stage where she could see objects, but she complained of their being fuzzy. Optic disks showed a degree of venous congestion and arteries appeared to be contracted. Nothing abnormal was discovered in the nervous system. Thirty hours later she had returned to normal except for a residual fuzziness of vision. Next day this had disappeared. There have been no apparent sequelae. The question of a possible hysteria arose and was considered, but the patient has shown no antipathy to treatment and has been twice refilled since without untoward effect.

CASE II

J. M., aged 19. Extensive tuberculous disease with cavitation in right lung. Artificial pneumothorax induced Sept. 20, 1944, and refilled at regular intervals. On the last occasion, one month after the above case, on the insertion of the needle for refill, before any air was passed and while a reading of −2,0 was being recorded, he suddenly complained that he felt dizzy. The needle was immediately withdrawn and the tip was found to be bloodstained. This patient did not lose consciousness, but he too complained of loss of vision. His pupils, particularly the left, were somewhat dilated; examination of the left disk showed in at least two arteries a short, moving, silver thread which was taken to be air; this disappeared in a few seconds, and perhaps fifteen seconds later the patient remarked, "I can see again now, but I still feel dizzy." After a few minutes' rest he rose from the table unaided, and has had no more trouble other than a slight staining of the sputum about half an hour after the incident.

COMMENT

Hamilton and Rothstein (*J.A.M.A.*, June 22, 1935) consider that air embolism occurs once in 500–1,000 cases, and that it is more frequent in patients whose pleura is thickened and in inductions. It was noticed in both the above cases that the needle seemed to pass through a thickened soft pleura. This has been confirmed in the case of Mrs. L. on later occasions, when refills have been carried out without incident. More satisfactory pressure readings have been obtained on these occasions.

The similarity of the condition to so-called "pleural shock" is noted. It was suspected after the first case that the true mechanism was air embolism, and the opportunity taken for immediate retinoscopy in the second case seems to confirm this.

These cases emphasize the points made by Hamilton and Rothstein: that the common practice of "blowing a little air through the needle to clear it" is one not unaccompanied by danger and is in fact to be firmly discouraged; and, secondly, that the tubing from the apparatus to the needle should be as short as possible and of fine bore. In Case II this could have been the only source of air.

Noranside Sanatorium,
Angus.

Reviews

A PIONEER FRENCH PHYSIOLOGIST

François Magendie. Pioneer in Experimental Physiology and Scientific Medicine in XIX Century France. By J. M. D. Olmsted, M.D. With preface by John F. Fulton. (Pp. 290. $5.00.) New York: Schuman's.

The celebrated François Magendie (1783-1855) had a curious upbringing. His father, a Bordeaux surgeon, as a faithful disciple of J. J. Rousseau, let him remain undisciplined and without schooling until he was 10 years old. Two years before that the family moved to Paris to enable the father to enjoy the violence of the Revolution to the full. When François enterd on his medical studies Napoleon was throwing medical education into chaos with his innovations. However, France then had so many distinguished physicians and surgeons that the intervention of the State was less disastrous than might have been expected. Magendie soon came under the influence of Bichat, who in his short life of 31 years made a great impression on medicine. To-day he is chiefly remembered by his carrying his anatomy beyond organs to their constituent tissues, though curiously enough he distrusted the microscope. But in his own day he was also known as a vitalist who held that all vital phenomena were marked by "an instability which distinguishes them from physical phenomena remarkable for their uniformity." On this Magendie, though himself a vitalist at that time, broke away from him, believing that this apparent instability was merely due to our ignorance. He therefore embarked on a study of experimental pharmacology and physiology—aspects which Bichat had neglected. From an investigation of the action of poisons on living tissues he went on to a study of absorption, deglutition, and vomiting. Meanwhile he was practising as a physician, and applied his scientific methods to the treatment of an epidemic of typhus in 1814. Throughout his life he advocated "expectant" methods of treatment and was strongly opposed to routine bleeding. He next turned to work on motor and sensory nerve roots; it would be tedious to relate the controversy this involved him in with Sir Charles Bell as to priority of discovery—a controversy which continued long after the death of both protagonists. Clearly each learnt from the other; but there was a lack of candour in Bell's attitude. After some work on hydrophobia which ended in the failure of his vaunted treatment by intravenous injections of large quantities of water, Magendie turned to the more fruitful subject of the functions of the cerebellum. Here again he became engaged in controversy, this time with Flourens. Magendie's two great defects as an experimenter were his inadequate use of controls and an obstinate adherence to the opinion he first formed. This is seen also in his work on the cerebrospinal fluid, where he correctly described the foramen still known by his name, but was wrong about the course of the flow and on the function he ascribed to the pineal. Hence in all his work we find many errors embedded in a mass of important discoveries. One disservice he certainly did to science; it was his ruthless experimentation that started the antivivisection campaign. Yet with human suffering he was tender and sympathetic; his fearlessness in trying to alleviate it was shown by his conduct during the epidemics of typhus and cholera. During his tenure of the professorship at the Collège de France he engaged with his pupil Poisenille in devising apparatus for observing circulation and respiration; but his most distinguished pupil, and later collaborator, was the famous Claude Bernard, with whom he carried out the initial experiments on the glycogenic functions of the liver.

All this and much more is to be gathered from Prof. J. M. D. Olmsted's admirable biography. In order to get a true portrait of the man he has combined the pictures drawn by three of his contemporaries: Claude Bernard, who chiefly regarded Magendie as the exponent of the experimental method; Dubois, who disapproved of his methods but liked him personally; and Flourens, who admired his scientific probity but condemned his intolerance and unwillingness to recognize that other investigators might occasionally be right. His opposition to the use of ether as an anaesthetic was a striking illustration of this, as was his obstinate belief that cholera was non-contagious because he never contracted it himself while working in the midst of epidemics. Claude Bernard sums him up in these words: "He was two quite different people" as a casual acquaintance and in the laboratory. "Affable and kindly . . . with the world at large, in the laboratory and in his scientific relationships his character changed completely." In a brief but cogent preface Prof. J. F. Fulton emphasizes the debt that all American physicians—and, we would add, British physicians—owe to French medicine of the early 19th century.

NEUROLOGY IN CHILDHOOD

Diseases of the Nervous System in Infancy, Childhood and Adolescence. By Frank R. Ford, M.D. Second edition. (Pp. 1,143; illustrated. $12.50 or 69s.) Springfield and Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox.

Seven years after Prof. Frank R. Ford had put neurologists and paediatricians firmly in his debt with his *Diseases of the Nervous System in Infancy, Childhood and Adolescence,* a second edition has been issued. It is clear that revision and rewriting has been widely undertaken, and the list of new material is long. The total number of references is now over 2,000, and nearly a quarter are new to this edition, which also includes 40 new illustrations and 11 new charts. It is, of course, impossible to check all the new material, but so far as can be ascertained Prof. Ford has not missed anything of serious importance. Penicillin has just got into a footnote, and its value in meningitis will need amplification next time. A topical subject now causing considerable anxiety in America is the effect of recent tonsillectomy in the aetiology of poliomyelitis. This is duly recorded, but without comment, and this is not the only place in the book where what Prof. Ford himself thinks is not made clear. The surveying of the literature is splendidly done, and the value of the well-known team-work at the Johns Hopkins Hospital is obvious. But modesty has kept the author a little too much in the background. Perhaps with the pruning that will be necessary for the next edition on grounds of sheer bulk he will keep this in mind. Meanwhile the second edition of Prof. Ford's book is a worthy production of the famous Baltimore centre and is assured of a warm welcome.

OBSTETRICS AND GYNAECOLOGY

The 1944 *Year Book of Obstetrics and Gynecology.* Edited by J. P. Greenhill, B.S., M.D., F.A.C.S. (Pp. 576; illustrated. 18s. 6d.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

The 1944 *Year Book of Obstetrics and Gynecology* follows the pattern of its well-known and popular predecessors. It comprises well over 500 pages, which are devoted almost equally to the obstetrical and gynaecological sections, and into these a wealth of interesting and useful information is compressed. As might be expected, considerable space is given to the subject of caudal anaesthesia, which has been much more extensively used in America than in England. The editor speaks enthusiastically of his personal experience of the method, but states that he does not believe that it will become "part of our obstetric armamentarium." Reference is made to penicillin therapy, but at the time the book was published few reports were available, and it is to be expected that next year much more space will be devoted to the use of this wonder drug. Readers who have found difficulty in understanding the literature on the rhesus factor will find an excellent summary of the subject on page 277.

This *Year Book* is an excellent institution, and it should be near the desk of every general practitioner and obstetrical and gynaecological specialist.

The Board of Registration of Medical Auxiliaries (B.M.A. House, Tavistock Square, London, W.C.1) has published a sixth edition (1945) of the Orthoptists Section of the National Register of Medical Auxiliary Services. Orthoptics (i.e., the practice and principles of the development of binocular vision in the case of squint) was recognized by the Board as a branch of medical auxiliary work on the recommendation of the Council of the B.M.A., and the Council of British Ophthalmologists and after investigation by the Board into the claim for recognition. Registered orthoptists do not undertake the treatment of any person except under the direction and control of an ophthalmic surgeon or a registered medical practitioner engaged in ophthalmology. Copies of the Orthoptists Register may be obtained free of charge from the acting secretary of the Board.

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY AUGUST 25 1945

NUTRITIONAL DIARRHOEA

Diarrhoea is common among people suffering from semi-starvation and malnutrition; as noted by Kenny[1] in a recent number of the *Journal* it adds to the difficulties of treatment, but usually clears up in a short time when the patients are given a milk diet. It has been attributed to a diet containing large amounts of cellulose and other indigestible materials, and to infections as a result of eating anything edible.

Diarrhoea is, however, one of the three "D's" that are regarded as characteristic of pellagra, and Heilig,[2] working in Mysore, found that chronic diarrhoea in malnourished persons was relieved by nicotinic acid. Aykroyd and Gopalan[3] have recently recorded a study of 54 cases of chronic diarrhoea not attributable to sprue or other known condition. The onset in these cases was gradual; all of them had vague abdominal discomfort, but no griping or tenesmus; the stools were not frothy and contained no blood. In all but 13 the number of motions was over six a day. Test meals were examined in 42 cases: free hydrochloric acid was absent in 28 and subnormal in 13. Evidence of nutritional deficiency other than emaciation was found in most of the patients. Forty-nine had glossitis: this was of the hypertrophic type, with fungiform or filiform papillae, in the early cases with diarrhoea of under four weeks' duration; and atrophic, with a red and smooth or a fissured tongue, in the more advanced and chronic cases. Anaemia was found in 46 cases; in all but three of these it was of the macrocytic hyperchromic type commonly found in pellagra. Fifteen had "crazy-pavement" dermatosis—that is, patches of epithelium of a darker colour separated by fine and irregular fissures. Only one had the typical symmetrical dermatitis of pellagra. Twenty-five had oedema of the dependent parts. The oedema and, possibly, the dermatosis and anaemia may have been caused by general undernutrition secondary to the diarrhoea; but the soreness of the tongue was noticed by the patients at the same time as, or a short while before, the diarrhoea started.

After admission to hospital all these patients, except some who were so severely ill that it was not justifiable to withhold treatment, were kept for four days on the usual hospital fluid diet. Little or no improvement was seen during these four days. Nicotinic acid was then injected intramuscularly. In the severe cases 100 mg. was injected daily; in the milder cases 50 to 70 mg., according to the severity. After the third injection the number of motions was reduced and the stools were more formed. In 50 cases the diarrhoea was controlled within twelve days. The four that did not respond were severe cases that had had diarrhoea continuously for over six months; when admitted they were grossly emaciated, with severe oedema. The soreness of the tongue diminished with treatment, and the patients were able to take a full hospital diet with little discomfort. The appearance of the tongue did not, however, become normal in any of the cases. Oedema gradually disappeared after the patients were able to eat a normal diet. No striking change in the "crazy-pavement" dermatosis was noticed. Achlorhydria or hypochlorhydria persisted in spite of treatment. It may be inferred that the diarrhoea in these cases was due to deficiency of nicotinic acid.

Rice contains little nicotinic acid, but typical pellagra is rare among rice-eaters in India (Aykroyd and Swaminathan[4]); although, as Aykroyd[5] points out, the recorded death rate from diarrhoea and dysentery in the rice-eating areas—Orissa, Central Provinces, and Madras—is four to six times as high as in the wheat-eating Punjab, where milk consumption is relatively high. The demonstration that vitamins of the B group can be synthesized by bacteria in the intestine and absorbed (see this *Journal*[6]) calls for a reconsideration of aetiology of diseases such as pellagra. It is possible that the diets of Indian rice-eaters commonly contain a factor that favours the growth in the intestine of bacteria that synthesize nicotinic acid. Apart from this, pellagra may be due to failure to absorb the nicotinic acid supplied in the food or formed in the intestine. The importance of absorption was shown in the cases considered, as nicotinic acid was not so effective when given by mouth as when injected intramuscularly. It is possible that the deficiency of nicotinic acid in the Indian cases was due to removal from the diet of the factor that favours synthesis or some factor favouring absorption. Pellagra is a multiple deficiency disease; differences in its manifestations may be due to differences in the adequacy or inadequacy of the factors that contribute to its prevention.

THE FUTURE OF POPULATIONS

Among the latest contributions to the literature of this subject are a volume of essays by British writers, each discussing an aspect the writer is well qualified to treat, and a comprehensive work by Dr. Alva Myrdal, a Swedish medical woman who has given many years of study to the whole question.[7] The first is described as an inquiry with recommendations; the second as a report on the Swedish experiment in democratic family and population policy.

The essayists have command of a more attractive literary style than has Dr. Myrdal, but she makes accessible to readers of English—or perhaps one should say American—a good deal of information hitherto available only in Swedish. We may interpolate here that this includes (Chapter XVI) a chapter on medical services which we should have liked to quote. We do not do so because the subject is controversial, and unless passages are given in full—for which there is no space—there is danger of bias in selection. The basal facts of population are, or should be, well known. In Great Britain, and in many other West European and North American States, the populations must eventually diminish; because, in each successive generation, the number of women of an age to bear children is decreasing. In most of these countries the populations will continue to increase in absolute numbers for some time, because improved death rates are permitting a much larger proportion of young adults to survive and swell the ranks of non-breeders. But when the stone has reached the summit of the hill it will descend rapidly on the other side. This is common ground to demographers. One of the essayists—Mr. Titmuss—gives a much-needed warning that a recent increase of the birth rate is, in all probability, a mere spurt explicable by wholly transitory conditions. There is also general agreement that the only hope of arresting the downward trend is, to state it quite bluntly, to put families with many children in an economic (including educational) position not less favourable than that of childless or one-child families. On how this is to be done there is no general agreement. We think, however, that Dr. Myrdal's investigations should do something to shame those persons who spend words and ink on insulting those younger and poorer than themselves. The joke about young people who prefer a "baby" Austin in the garage to a baby in the cradle was never a good one. Dr. Myrdal provides detailed budgets of families with 0, 1, 2, etc., children, showing the amounts spent on various items. Here is her well-justified comment: "Even if the whole recreational item in the budget of the more well-to-do childless family were omitted it would hardly pay for one child and still less for several." The common people of England (and other countries) are alternately praised (at elections) and insulted. It might be well to remember Chesterton's lines:

> "Smile at us, pay us, pass us; but do not quite forget.
> For we are the people of England, that never have spoken yet."

One of the essayists, Dr. Grace Leybourne-White, notes that even if the White Paper proposals are carried into effect the wealthy will still have a great advantage over the poor in providing for the education of their children. That is true of almost all items on the programmes.

We find it hard to close on a note of optimism. The British people, like the Swedes, may be proud of what has been done within a generation to improve social conditions. But improvement *must* be slow in a democracy which is also a nation valuing its traditions. If the essayists and Dr. Alva Myrdal are right—and we believe they are—a social reconstruction far more sweeping than the generation now old has experienced must be effected within another generation, under the threat of a disaster which is not imminent, which will not be experienced by a majority of those now living at ages beyond, say, 40—viz., that fraction of the people which is politically vocal and powerful. The threat is from the intellectual point of view grave, not from the emotional point of view. The gibe, that posterity has done nothing for us so why should we bother about posterity, has more point than the "baby" Austin joke. It paralysed statesmen in face of a more imminent disaster which almost destroyed European civilization.

TAKING THE WATERS

Medical treatment has always evolved from the magical to the rational. These two methods have often existed side by side, and indeed in some respects continue to do so. As if to mark the contrast between them the Aesculapian Temple and the School of Hippocrates were two miles apart in the small island of Cos. But both schools believed that treatment was best carried out in healthy, attractive surroundings and in the therapeutic value of water. When science was eclipsed in the Dark Ages water naturally was credited with magical properties again, especially if drawn from a saint's well. And even when the darkness gradually cleared a belief in the therapeutic value of spas and springs "rationalized" the old magical ideas. But as time went on and knowledge of pharmacology increased these claims were challenged. Sir William Osler, in particular, was a terse critic. Only to quite a limited extent did the spas meet the challenge by carefully controlled observations to elucidate the alleged value of the ingredients of their waters. For the most part they replied by installing physical methods of treatment; in this they were wise, even if thereby they did not show any excessive confidence in such ingredients.

In this country Harrogate has always maintained its reputation largely because of the progressive attitude of its corporation, which has now taken the enlightened step of asking Prof. Stanley Davidson to investigate the whole situation and to make recommendations. His published report is of much interest and value, for it is both destructive and constructive. To take his negative conclusions first. He does not believe in a specific therapeutic action from any mineral water, and "the cure of anaemia is far more effectively and cheaply obtained by taking two or three shillings' worth of iron tablets than by drinking chalybeatic waters." Of course many mineral waters are laxative or diuretic, and thus by elimination assist other methods of treatment. He notes that the number of persons undergoing spa treatment has been steadily falling off for the last 20 years. This he attributes to the decline in over-eating and over-drinking, and to the redistribution of wealth by heavy taxation, which chiefly affected those who made use of spas. Although these factors will continue to operate, nevertheless Prof. Davidson considers there is a distinct future for well-planned spa treatment. Like the Aesculapians he believes in the value of pleasant surroundings and cultural amenities as important adjuncts, and if there are fewer "idle rich" there are plenty of tired and harassed men and women to whom this is the first need.

Though Prof. Davidson evidently thinks the principal virtue in the drinking of mineral waters lies simply in H_2O, he believes in its external use, and where there is a thermal spring there is saving of money and labour in making use of its warmth. The Vichy douche and the deep pool are commended, and he advocates the installation of a "fog room" (such as the vapours of Mont-Dore provide naturally) for the treatment of sinusitis, bronchitis, and asthma. On the other hand he is more doubtful of the advantages of colonic lavage. He would like to see some of the space occupied for this purpose utilized for other forms of physiotherapy, in which he is a firm believer. He does not recommend sulphur water externally for skin diseases, while internally its bactericidal action is negligible. He recognizes the value of the research work done at Harrogate in conjunction with Leeds University, and presses for its extension, particularly in the investigation of rheumatic diseases, which in panel practice account for one-seventh of the total incapacity of the insured population.

Apart from local questions of organization most of Prof. Davidson's conclusions apply to spa treatment in general, and he has helped to clear the air of both credulity and undue scepticism. As he says, when a patient goes to a spa for treatment he is willing to submit to a certain amount of discipline. The treatment is carried on daily, and adequate periods of rest are enforced. All this is very different from ambulatory treatment at home and obviously more efficient. It is often urged that the Continental spas organize the patient's daily routine more completely, but then, curiously enough, as Prof. J. W. McNee once pertinently put it, the British are more disposed to accept medical orders if they are couched in broken English. In any case the chaos on the Continent will dissuade visitors from this country from going there for treatment for a good many years to come. It is therefore an opportunity for British spas to set their houses in order and to avail themselves of the most recent scientific knowledge, recognizing both the limitations and the efficacy of their resources. The Harrogate Corporation is to be commended for the courage with which it put its faith to the test, and Prof. Davidson's report has justified that faith in many particulars while making helpful suggestions for future rational developments.

FURTHER RESULTS WITH D.D.T.

Since our first general account[1] of the insecticide D.D.T. a great deal more information has been published on its applications and its possible hazards in use. In February, 1945, an address[2] by Prof. Buxton to the Royal Society of Tropical Medicine summarized the progress made in utilizing the insecticide against a number of insect-borne diseases. Yet another successful application has been demonstrated in the use of D.D.T. powder against rat fleas,[3] and this should be of much value in combating bubonic plague and murine typhus; quite recently there was an urgent demand for D.D.T. in Malta, where four cases of plague were reported.

With the wide range of uses to which D.D.T. might be put it was of high importance to investigate carefully all possible toxic hazards to man. Investigations were made in a number of laboratories in this country and in the U.S.A., and the results of some of these were commented on earlier in the year.[4] Since then there have been several notable additions. Neal and his co-workers[5] studied the possible risks of inhaling D.D.T. from aerosols, mists, or air-borne dusts, and on the whole their results are reassuring. Of particular interest is the publication in this *Journal*[6] of Prof. G. R. Cameron's work on behalf of the Ministry of Supply. The figures for lethal doses obtained by him and Burgess are fairly close to those of American toxicologists, with the exception of those for rats. In the British experiments rats were decidedly more resistant than rabbits and guinea-pigs, whereas two groups of American investigators found them to be much more susceptible. The general picture presented, however, is the same: D.D.T. is practically safe as a dry powder and in dilute (e.g., 0.5%) solutions. Repeated contact with concentrated solutions is dangerous, but early warning of intoxication is to be expected in anorexia. If contact with D.D.T. ceases as soon as more advanced symptoms (tremors) occur there is every expectation of complete recovery. This is confirmed, if anything, by the published account[7] of a case of human poisoning with D.D.T. The exposure (to a concentrated acetone solution) was far in excess of that to be encountered in the practical use of D.D.T., so that it does not invalidate the conclusion that in ordinary circumstances it is without danger. Cameron and Burgess tested the possible influence of D.D.T. contamination on the rate of healing of wounds: a single application of 5% powder to open wounds was found to be without effect.

From descriptions of symptoms and delimitation of the toxic doses the next step in D.D.T. toxicology is to seek an antidote. Some Brazilian workers claim that injection of calcium salts (10% calcium gluconate) accelerated recovery of dogs from the effects of D.D.T., and also that preliminary injections give considerable protection.[8] Smith and Stohlman find a very substantial antidotal effect from the hypnotics dilantin and urethane, especially the latter[9]; they also observed that D.D.T. is excreted in large amounts in both urine and faeces. A later paper[10] describes the technique of extracting the drug from urine: unaltered D.D.T. was obtained from an ether-soluble fraction of the urine, and an unidentified chlorine-containing compound (possibly a degradation product) was detected in a fraction soluble in alkaline water.

LANCASHIRE LOOKS BACK ON TUBERCULOSIS

Not many specialists of high accomplishment can look back over thirty years spent in catering for the tuberculosis needs of two million people. When Dr. Lissant Cox took up office in 1913 the county scheme did not exist. Cases had been notified for only a few years; a meagre number of beds were used in private sanatoria, and 112 per thousand of the population died from tuberculosis. To-day the corresponding figure is 50, and the difference between these two death rates is an epitome of progress in the Lancashire Tuberculosis Scheme. In the last year the scheme has been further strengthened by the operation of mass radiography and the new maintenance allowances. The county borough of Blackburn has seen the wisdom of joining in with the Lancashire County Council for tuberculosis purposes. Other non-tuberculous chest diseases show a tendency to come into the purview of the Tuberculosis Service, and the *x*-ray diagnostic tentacles have spread out to the nursing and domestic staff in wartime nurseries. The deaths from pulmonary tuberculosis in 1943 were the lowest on record. All this and much else forms an enthralling chapter in preventive medicine.

Mass radiography is carried out in Lancashire by members of the county tuberculosis staff, and the special *x*-ray unit has been stationed at various large factories in the area, and also at Warrington. Sixty-nine active cases of pulmonary tuberculosis, about half of them with positive sputum, were discovered in 1943 through mass radiography—a figure of 3.5 per thousand examinations. This is thought to indicate the presence of some 800 still undiscovered positive-sputum cases among the total factory population in the county who would be discovered through the operation of further *x*-ray units. But of course mass radiography will give even more beneficial results in finding early cases.

We may read between the lines of Dr. Lissant Cox's wise and suitably restrained remarks on the value of fuller co-operation with the smaller county boroughs. The example of Blackburn may be the forerunner of closer liaison with other similarly placed administrative areas which now have their own tuberculosis schemes that exist like islands in the centre of Lancashire county. Every student of tuberculosis control will agree as to the value of the larger unit and the grave handicaps suffered by smaller areas.

We are at the point when the first-fruits in a second generation can be gathered from the county tuberculosis scheme initiated thirty years ago. Dr. Lissant Cox, in reviewing the brilliant record shown in his report for 1943, is perfectly right in stating that prevention can yield a greater dividend than treatment, though he is still looking for the ideal and still undiscovered chemotherapeutic substance which will attack the tubercle bacillus and make treatment as a whole more effective than it is to-day. Cautious reference is made to the supervision of the health of nurses and domestics, especially in regard to the new administrative procedure whereby they are directed to work in sanatoria. The whole report, though abbreviated compared with those sumptuous volumes we remember from Lancashire, is much more interesting than such compilations usually are. Dr. Lissant Cox has good cause to be satisfied when he looks back on his first thirty years in building the Lancashire Tuberculosis Scheme. The immediate future is full of doubt, but with this excellent foundation it ought to be possible to weather the dangers of the next few years, when there will be fewer beds and houses, fewer doctors and nurses, than a developing medical service requires.

WORLD CONTROL OF NARCOTIC DRUGS

A meeting in London of the Permanent Central Opium Board was made the occasion of a press conference at which the president, Sir Atul Chatterjee, gave an account of the world drug position. The Board wishes to return to pre-war conditions of control. All countries signatory to the Conventions (that is, every considerable country with the exception of Argentina) are required to send in estimates of their needs of narcotic drugs for consumption, manufacture, or export for the coming year. These are examined by the Supervisory Commission—an allied organization to the Board—and no country is allowed any excess of the figure without submitting a supplementary estimate. At the beginning of the war every Government was asked to keep intact national control and to collaborate with the Board in international control. But during the war some retrogression has taken place in many countries, especially those with colonial territories. In ordinary times the Board receives some 1,500 returns annually from metropolitan Governments; by 1941 this number had fallen to below 1,000, but there has been a recovery. The Axis or Axis-occupied countries are the chief defaulters, but the Soviet Union has ceased sending returns since it severed its connexion with the League of Nations. Spain, although ratifying the Convention, was tardy in making returns even before the war, and during the last five years has made no annual returns, in spite of repeated reminders. It is hoped that Italy will soon resume collaboration, and that in Germany the military government will ensure adequate domestic control. Much of the trouble which arose after the last war is ascribed, rightly or wrongly, to the fact that military control was not watertight. Evidence shows that control is being resumed or continued in Belgium, the Netherlands, the Scandinavian countries, and France and French territories in North Africa. No information has been received in recent years from the Baltic States, or from Greece and Bulgaria and other countries in South-Eastern Europe. The position in the Far East is obscure. Japan ceased collaboration at the outbreak of war; China has continued to collaborate so far as is possible. There have been no returns from the Dutch East Indies, Siam, Indo-China, and Burma. In Iran there is a large production of raw opium, but that country has not ratified the Convention of 1925, and has not given any satisfactory figures of production or of exports. In Egypt and in India the control remains strict. In South America the situation varies from country to country. Internal as well as international control is satisfactory in Colombia. Argentina, although it has not ratified the Convention, sends full returns. In Peru, a cocaine manufacturing and exporting country, there has been great improvement, but in Panama and some other places in Central and South America control can hardly be said to exist.

No country has denounced any of the Conventions, and although in some countries internal control has been lax an effort is now being made to re-establish and reconstruct control within the country and control of its part in international traffic. The Permanent Central Opium Board opened a branch office in Washington at a time when the United States was still neutral. The Washington office is now to be closed, and a return is to be made to Geneva. The relationship of the Board to the new United Nations organization will be the subject of negotiation during the next few months.

JOINT EFFORT IN SOCIAL WORK

The eighth annual report of the British Federation of Social Workers has been issued from 5, Victoria Street, S.W.1. The aims of the Federation are to promote greater efficiency in the conduct of the social services, the advancement of social and industrial welfare and of health, and, generally, the well-being of the community and its improvement. The keynote of the work is interchange of knowledge and experience between the constituent organizations, which now number 14. Last year was one of consolidation. Various important pieces of work which prepare the ground for future expansion have been concluded. The Council of the Federation not only has supplied information and offered suggestions to various Government Departments but has been called in and consulted when small meetings were held on matters of urgency—such as the Hankey Interdepartmental Committee on Further Education and Training when the post-war supply of social workers was under consideration, and the Resettlement Advice Committee of the Ministry of Labour when setting up its new centres. The planning of new services called attention to the need for new staff and hence for training; the return of disabled soldiers and industrial casualties raised most acutely the problems of rehabilitation; the prospect of demobilization brought resettlement into the foreground. Training and restoration to working capacity, and the care of children, occupied chief places in the programme. After visualizing and amplifying some of the needs of the social services as set forth in the Beveridge report, the Beveridge Study Group (an *ad hoc* body of seven people) turned to the interpretation of function as defined by each constituent association in the light of its own work, and boldly brought conflicting interests and views together without committing the Council.

Two separate reports—one on the needs of society and the other dealing with function—were presented at a delegate conference. By their nature these reports provoked comment and criticism and a further probing into the matter. "Lively controversy broke into the usually peaceful atmosphere of the office. Indeed, the very essence of federation work had at last been brought into being." Rehabilitation was tackled with equal energy, and a subcommittee for the purpose is now continuing its work in co-operation with a tuberculosis subcommittee; it is also studying the needs of returned prisoners of war. A third big subject—how best to care for the unwanted or problem child, or the child with a broken home—has been broached, but the main task lies ahead.

PREMEDICAL ZOOLOGY

BY

M. ABERCROMBIE

AND

M. L. JOHNSON

Zoology Department, University of Birmingham

In the present widespread discussion of medical education the teaching of premedical science is not receiving the detailed criticism it deserves and needs. The Goodenough Committee[1] recorded much dissatisfaction with the usual course of instruction, but made no concrete suggestions about the scientific background which medical students should have. The Moran Committee[2] made some valuable points about the university premedical year, but left details to the teachers concerned. It is desirable that teachers of premedical science should state their views for criticism by their medical and scientific colleagues. In offering the following suggestions for modification of the zoological part of the First Medical Course we are assuming that at least for several years a considerable proportion of students will continue to take this course at a university. We feel, however, that our proposals are also relevant to premedical teaching in schools.

It is generally agreed that zoology can contribute two things to medical education: (*a*) Training in scientific attitude. Zoology, the nearest of the premedical sciences to medicine, is particularly suitable for the initial training of medical students in scientific method. (*b*) Knowledge of biological principles basic to medical science.

In order that these contributions shall be adequately made, we believe that there are two major necessities, in both of which contemporary courses are seriously deficient: (1) *A large part of the teaching must be primarily and deliberately directed to training in scientific method.* (2) *Factual material must, where possible, be drawn from the biology that is important to man and relevant to medicine and not from "pure" or "academic" zoology.* We will discuss these two points separately.

(1) Training in Scientific Method

Our experience of zoology teaching has shown us that the assimilation of scientific facts does not of itself automatically lead to an understanding of scientific method, nor does it inculcate scientific habits of thought. The essentials of scientific method must be quite explicitly taught, and training in scientific habits quite deliberately undertaken. Such instruction is not specifically provided for by the usual university teaching techniques of lectures and demonstrations, which are designed to present factual material as quickly and easily as possible. Indeed, however much the intention of training in scientific method is affirmed in syllabuses, one can find little trace of it in examination questions, which may be taken as indicators of both the treatment and the content of a course, and which certainly strongly condition the attitude of students. The traditional system of instruction thus contributes to, or at any rate fails to correct, the deficiencies of the average medical graduate noted by the Moran Committee[2]: "He tends to lack curiosity and initiative; his powers of observation are relatively undeveloped; his ability to arrange and interpret facts is poor; he lacks precision in the use of words." It is as though we fed our students always through a stomach-tube. We choose their meal carefully, prepare it suitably, insert it efficiently, and deny them scope to develop the use of their senses, powers of discrimination, and voluntary muscles. Training in scientific habits must be the primary business of much of the teaching and not, as traditionally, a subsidiary and often imaginary by-product of factual instruction.

For instance, one of the most important scientific habits for successful medical practice is that of unprejudiced observation. Yet it is usual to give students full information about material they will subsequently see in the laboratory. This may be the quickest way to get students to absorb as much knowledge as possible in a short time, but it is not the best way to train them to observe carefully, to record accurately, and to interpret what they see. Indeed, results of an experimental class test showed that pre-knowledge in students of what they expect to see *inhibits* careful observation.[3] Many practical classes should be designed to make students find things out for themselves, even if the factual knowledge they so acquire is only a small fraction of what traditional methods give them in the same limited time. In our opinion it would be far better if students were taught less and found out much more.

We do not propose in this article to be more concrete about methods of training in scientific method, partly because we want to emphasize generalities, partly because the necessary new teaching techniques cannot be deduced from first principles, but must be developed by deliberate experimentation. We might suggest from our experience, however, that, since an important part of zoology practical classes must consist of training in the technique of dissection, a useful step is to give dissections so far as is possible in the form of problems. Training in observation, recording, and interpreting can be introduced at many points in practical work. We have found training in the process of experimentation more difficult to devise; biology is here at a disadvantage in comparison with physics and chemistry. It is difficult to find valuable experiments which are not better done subsequently in the physiology course. Finally, it is important to introduce students to elementary statistical procedure.

(2) Subject-matter of the Course

We now come to consider the subject-matter. It is our opinion that those aspects of zoology which are relevant to human affairs have most to contribute to medical education. We will discuss our reasons for this opinion under two headings: (*a*) the value of what we may call "human" zoology, as part of the mental equipment of students; (*b*) the value of human zoology in promoting the process of learning.

(*a*) Human Zoology and Mental Equipment

It is surely a reasonable view that biology relevant to human affairs should be an essential part of the culture of a citizen of democracy, because control of the development of human society demands such knowledge. This attitude has been expressed recently by Hogben,[4] and we need not discuss it further. If, however, human biology is important for every citizen, it is doubly important for doctors. Medicine is, after all, a field of human biology, and doctors are directly concerned with many biological problems.

The content of most elementary syllabuses, however, has clearly not been designed with the above consideration in mind. The relative emphasis given to different major principles or branches of zoology is quite arbitrarily determined in the traditional course. It certainly cannot be said to give a balanced picture of modern academic zoology. Still less does emphasis in the course reflect importance for the general citizen. The principles of comparative morphology are chosen for special emphasis, though this is perhaps the least important branch of zoology when man is the centre of interest. More important principles may also be taught, but almost always with illustration by factual material of unnecessarily little human interest —for example, parasitism exemplified by *Monocystis* and *Taenia*. A great deal of factual material has neither relevance to any biological principles nor any intrinsic human importance —we refer especially to much of the detail of the "type" animals and embryos.

It may nevertheless be said that the educationally important principles are most soundly taught in the traditional way through carefully selected aspects of "pure" rather than through "applied" science, and that application of the principles to practical problems can be left to the student to make as he finds it necessary. We cannot agree with either of these contentions. Useful animals and plants exemplify most biological principles just as well as those which have no social importance. For instance, the principle of the circulation of matter can be taught as well through the biology of fisheries or of sewage disposal as of ponds or heaths. And the principles of physiology can be taught as well with reference to man as to the traditional frog; indeed, better, since human physiology is so much better understood.

As regards subsequent application of general principles to practical problems, it is the usual experience that a general principle is not at all easily applied in an unfamiliar context. A student is likely to apply his knowledge of general principles to human affairs only if he already knows how it does apply. An interesting experiment has shown the advantage, from the point of view of handling social problems, of integrating human applications with scientific fundamentals in the teaching of genetics.[5]

(*b*) Educational Value of Human Zoology

The educational value of a zoology syllabus which takes man as its centre is not the only point in favour of such a course for medical students. We believe that the material will be more readily learned and retained than will that of traditional zoology. As a recent report[6] points out, human zoology has the advantage of starting from the everyday biological interests of all students. Its particular importance for medicine can easily be made plain. The interest of the keen medical student who tends to be impatient of the apparent irrelevance of the traditional course is therefore readily captured, and learning is much facilitated. Further, if the subject-matter is relevant to medicine, there is less danger that the biological principles which the course illustrates, and the scientific attitude which it is supposed to inculcate, will be jettisoned as the student proceeds to his medical studies. He will be reminded from time to time of his biological training, and a real link between premedical and subsequent years will be developed. The importance of making such links between the various parts of the medical course is emphasized by the Goodenough Committee.[1]

A link can, for example, readily be made with the preclinical years by discarding, in lectures on vertebrate anatomy and physiology, all "type" animals except man. These lectures can put the most general aspects of human anatomy and physiology into their background of the anatomy and physiology of all animals. The amount of duplication of preclinical work will obviously be negligible in a short course, but the material can be made a useful introduction to subsequent work and a permanent link between broader biological principles and later specialization.

We have recently also experimented with the frequent use of medical exemplification in discussion of physiology, parasitology, and genetics in order to make quite clear to students that the general principles they learn are a valuable part of their medical training.

Here we are on controversial ground. While most educationists would agree that every attempt must be made to give sound training in scientific method, and many might agree that emphasis should be put on the *human* aspects of biology, we are well aware that our suggestion that biology should in addition be given a *medical* flavour may seem to run counter to the commonly held view that premedical science should be non-vocational. Let us explain, however, that we do not propose that students should in any sense be given a preliminary course in medicine, but merely that when the course can be illustrated and exemplified by obvious applications to medicine the opportunity should not be missed. Advantage should be taken of the fact that, for instance, the pathology of processes is sometimes a convenient natural experiment which reinforces the evidence for any generalization. And for examples of parasites we prefer to use those of medical importance—the malaria parasite rather than *Monocystis*, and hookworm rather than tapeworm.[7] The number of medical facts which students learn in this way will be negligible; their importance lies in capturing the interest of the keen medical student and to some extent in helping to integrate biological with subsequent medical studies.

Such a medical flavour introduced into our zoology course during the last two sessions produced a strongly favourable response in anonymous questionaries returned by students. To adapt a legal dictum, we may say, therefore, that a premedical course should not only be relevant to medicine but be manifestly and obviously seen to be relevant.

We have indicated that we believe that human zoology is a more suitable general training for every kind of student than the traditional first-year zoology. We have no need, therefore, to segregate medical from science students, and we agree with the Goodenough Committee that such segregation is undesirable in the early stages of education. We should add that the introduction of a medical flavour into elementary zoology does not necessitate such segregation. The time occupied by medical exemplification is inconsiderable, and, incidentally, science students also find such a course more interesting than the traditional one.

Conclusion

We suggest, therefore, that the subject-matter of a premedical course should be designed as an introduction to the study of man in relation to other animals. To clarify our proposals we give in brief outline the sort of course in zoology we have in mind.

1. The earth as a habitat; the circulation of matter and the place of animals therein; the animal kingdom and man's place in it; the history of animals.
2. The physiological anatomy of man against a background of other animals and in relation to habitat. This survey should be discussed round a central theme, such as the maintenance of constancy of the internal medium in the land habitat.
3. Sex and development, omitting details of morphological embryology.
4. Genetics applied to human and agricultural problems. Special emphasis should be placed on the relation of nature and nurture, which is of such fundamental importance in medicine and social science.
5. Evolution; the uniqueness of man; the contrast between cultural and organic evolution.
6. Pests and parasites of man and domesticated animals and plants, and their control; in particular, malaria and hookworm studied from biological and social aspects.
7. Animal populations and the relations between animals; food chains illustrated by the biology of fisheries and of sewage disposal.

Throughout the course a deliberate attempt must be made to inculcate desirable habits of thinking. While this can be done during lectures by explicit precept and by implicit example, the process would undoubtedly be very much speeded up if staffing arrangements would allow the development of a tutorial system. The following points are among those we think should be insisted on:

Elementary semantic discipline: avoiding verbal confusion; understanding the potency of "word magic."

The changing system of knowledge; the importance of flexibility of mind and of avoiding dogma.

The importance of unprejudiced observation and of controlled experiment; the evaluation of evidence from a variable population obtained with variable techniques; the role of techniques and their limitations, including the use of experimental animals.

Summary

To play a useful introductory part in the medical course, premedical zoology should concentrate on: (1) training in a scientific approach to biological problems; (2) provision of an introduction to the study of man in relation to other animals.

Official figures show that the number of blind persons in this country has increased by nearly 150% in the past quarter of a century. The number was 30,785 in 1920; it has risen to 76,145 in the latest count. But the National Institute for the Blind explains that the statistical increase may be more apparent than real, as the official figures refer only to people who have been actually registered as blind. The registration system is much better to-day than it was 25 years ago. At the same time the Institute considers there is much more blindness than need be, and that thorough preventive measures should be taken. It does not intend to make any separate appeal for this part of its work, but it is urging the Government to include ophthalmology in the National Health Service. One urgent need, according to the Institute, is the creation of more research and treatment centres similar to that at Oxford. There should also be a vigorous campaign to make the public "eye-conscious," more aware of the dangers that threaten sight.

REHABILITATION OF THE DISABLED

A conference was recently held at Oxford under the auspices of the Southern Regional Office of the Ministry of Labour and of the Nuffield Organization, when 250 industrialists were addressed on various aspects of rehabilitation. The medical aspect was dealt with by Mr. G. R. Girdlestone and Lieut.-Col. J. W. T. Patterson.

The Hospital Team

Mr. Girdlestone described some of the features of a good orthopaedic hospital, the things at which he had aimed in the initiation and development of the Wingfield-Morris Orthopaedic Hospital at Headington. A complete team of experts was needed, he said, for the nursing, feeding, surgery, physiotherapy, occupational therapy, and other needs—including diversion—of the patients. It was difficult to get together the members of such a team, and mistakes were sure to be made. A few would not fit and would go, but many would respond to the infection of the place. "To join in so wholesome a common task tends to breed the right kind of men and women."

The first thing to be done was to win the confidence of the patient and enlist his co-operation. What a man learned to do for himself was the mainspring of his recovery. Education was the secret of his treatment—education in the true sense, which meant making something wholesome and true grow within him.

Mr. Girdlestone went on to say that one of the great contributions of orthopaedic surgery was the knowledge, now widely accepted, that the way to restore movement, power, and skill to a damaged part was the natural and easy activity in some purposeful employment. In hospital the occupational therapist devised a plan of work which would bring into use the damaged part with increasing range and power, but the management in industry must complete what the occupational therapist had begun, and go out of its way to help the man through the first period of awkwardness and discomfort. Special handles to tools and similar devices facilitated the use of the damaged part, and until the man's recovery was complete or he had contrived new ways of accomplishing the old craft, his progress must be watched and the scope and requirements of his work adapted to keep pace with his improvement.

Whether the disablement was moderate or severe, it was the man's response that mattered—his response, on the one hand, to the pain and trouble occasioned him, and, on the other, to the kindness and skill which were at his service. It was for those of them who worked in hospitals to induce the favourable response by good nursing, feeding, and surgery, and by reassurance and the taking of trouble to show the man what was happening and what was the aim in view. That disabled men did make a special effort and did succeed had been proved by a recent investigation in the United States,* in which it came out that disabled men held their jobs more consistently than the uninjured. Given the right hospital and the right management, disabled men responded magnificently.

Reinstatement in Industry

Col. Patterson agreed that successful reinstatement was a matter of team work on the part of the many people involved. All members of the team must, as a first essential of success, understand something of the central figure in the problem—the disabled person himself—and be able to analyse his reactions and the personal adjustments he had to make in facing his disability. They must also study the various reactions which, as members of the general community, they experienced in the presence of the disabled person, and must determine whether their attitude was justified or whether it was based, as it so often was, on weak sentimentality, deep-rooted prejudice, or, worst of all, indifference.

He went on to trace the history of a disabled person from the time, previous to his disablement, when he was called upon to exchange his civilian career for a military one, his painful adjustments to Army discipline, his experience of battle, the first shock consequent upon his injury, and afterwards the depressing prospect, domestic and industrial, which opened out before him, his insecure replanting in the world to which he had formerly belonged, and the skill and care required of those in whose charge he was if his readjustment into the old environment was to be accomplished without disaster. Often the general attitude of the community towards these disabled individuals was the outcome of ignorance of the facts or was born of a sloppy kind of sentimentality which got nowhere. The disabled man's ambition was to be regarded as normal, whereas many of those who met him were inclined to regard him as an interesting exhibit and wanted to be told at once in detail how it all happened, while others went to the opposite extreme, and in their endeavour to pretend that they had noticed nothing amiss became most unnatural in their conversation and embarrassed everybody concerned.

Col. Patterson set out the following points for consideration:

Frequently the sheer necessity to overcome disability brought out talents and attributes which otherwise would never have been developed.

It was not always a tragedy that a man through injury was unable to return to his old job; possibly he was never really happy in it.

Despite new means of destruction, the varying types of physical disability have changed little since Waterloo or earlier; what has changed is surgery, which has been improving all the time.

Fifteen years from now among those who had come through the war with no physical disability would be some who had made a success of civilian life and others who had failed miserably, and it was doubtful whether the ratio of successes to failures would be higher among the disabled.

A Medical Assessment

Any reinstatement of disabled persons in industry, said Col. Patterson, must start with an initial medical assessment, based, he suggested, on seven qualities: (1) physique or general constitution, (2) arm or upper extremity efficiency, (3) locomotion or lower limb efficiency, (4) hearing, (5) vision, (6) mental capacity, (7) emotional capacity. Each of these seven qualities should be assessed in one of five degrees, the number 1 being given for the highest assessment and 5 for the lowest. It was then important to determine whether, with any quality which was assessed at a low rating, the rating could be improved by remedial treatment.

Having carefully assessed the individual it was necessary to make certain of his correct employment. An analysis ought to be made of all industrial employments similar to the analysis of Army employments, from the point of view of the minimum physical and mental demands of each, expressed in the same terms as the assessment of the individual just discussed. Thus it would be possible to set out in main groups the jobs of similar type from the point of view of training and experience and general qualification.

These assessments, in Col. Patterson's opinion, called for a special team of men some of whom would be technical industrial officers with a wide knowledge of labour conditions, and others medical men with experience of physical and psychological examination. Further, it would be of immense value to know what Army and civilian employments were equivalent. Having decided the main group into which the man fitted most appropriately, the next step would be to "marry" the ciphers indicating the assessment of the individual to the ciphers corresponding most closely among the list of individual employments, thereby indicating the correct specific employment of the man within the main group employment or trade. Then came the final stage of resettlement, which must be undertaken with understanding and tact. A programme of graduated resettlement training should be laid down for all the men concerned, with opportunities for general and specific education in working hours.

HELPING THE BLIND TO SEE

It is thought that some of the scientific devices used in the war in direction-finding, radiolocation, and "blind" flying may have something to contribute to easing the life of the blind person, and preliminary research into the subject has already been done at St. Dunstan's. A blind person walks about alone by using his sense of hearing for direction-finding and for locating his position by reflected sound. One of the newest developments is a guiding device, made by Captain H. G. Round, which transmits a beam of light and receives the reflected ray. Preliminary tests have justified further work, but

---

* In a recent review carried out by the Western Electric Company accident rates have been found to be higher among the unhandicapped than among the handicapped, and 7% more of the able-bodied were losing time through absence from work.

Sir Ian Fraser emphasizes that the device is in its very early stages and blind people must not expect any help from this or anything similar in the near future. The Council of St. Dunstan's has, however, set up a committee, under the chairmanship of Prof. E. D. Adrian, to be known as the Sensory Devices for the Blind Committee, which will investigate not only guiding devices, but also methods whereby the printed word in an ordinary book can read aloud to the blind; an improvement of recorded "talking books," braille machines, and other apparatus. Through the generosity of an anonymous donor enough money has been made available for the committee's work for five years. It has already met twice, and on its advice St. Dunstan's has decided to set up a research unit with a full-time research physicist and a biologist. The research work will include investigations into the better use of the little glimmer of sight that remains with many people who are technically blind, and the substitution of the other senses for the sense of sight.

MENTAL HOSPITAL POPULATION: PROPOSAL FOR DISPERSION

A proposal for reform of mental hospitals which would change the atmosphere of these institutions and abate the public fear of them, which is a handicap to psychiatric treatment, was made by Lieut.-Col. J. Ivison Russell, medical superintendent of the North Riding of Yorkshire Mental Hospital, at a meeting of the Mental Hospitals Association recently held at Guildhall, London. The fact that the mental hospital is considered as a last resort—a place for the reception only of those cases which cannot be managed elsewhere—is undoubtedly a great hindrance to the acceptance of the mental hospital as a main centre for the treatment of mental illness. By the Mental Treatment Act the mental hospital is legally recognized as a proper place for the treatment of psychoneurosis, but that legislation does not give the hospital any popular appeal, and the fact remains that people are afraid of mental hospitals and will remain afraid of them until they are drastically reorganized.

Col. Russell said that the most objectionable peculiarity of the mental hospital is its habit of retaining a large number of "settlers," and he thought this number could be reduced. The settlers include four main classes, amounting to 70% of the total. There are 5% who are recovered but homeless, and who would probably not have sufficient stability in a competitive community. Then there are something like 45% of chronic psychotic cases, 10% of seniles, and 10% of mental defectives. Col. Russell's proposal is that the recovered cases, the seniles, and a proportion of the chronic psychotic cases could be more suitably accommodated in subsidiary homes, and that congenital cases should be treated in mental deficiency colonies. The recovered cases would be transferred to a resettlement unit remote from the hospital. Many of the chronic psychotics could be adequately supervised in after-care homes in a rural environment; and separate infirmaries would be instituted for senile patients. All these remote units would function as integral parts of the mental hospital, which would be conceived as a group of therapeutic centres rather than as a single unit.

As for mental defectives in mental hospitals, Col. Russell's recommendation is that every patient before admission to hospital should be seen by a psychiatrist whose duty it would be to advise on the appropriate institution, and in the case of transfers between mental deficiency colonies and mental hospitals the concurrence of the medical officer of the receiving institution should be required.

This would leave the headquarters hospital, with an annexe at a distance of 300 yards or so. In the annexe would be those chronic psychotics who, owing to abnormality of behaviour, were unfit for transfer to after-care homes. At the main hospital the reception wards for depressive and anxiety states on the one hand and for states of excitement and socially disagreeable behaviour on the other should be in separate buildings. The administrative offices, progress wards, special treatment rooms, out-patient consultation rooms, occupational centres, operating theatre and laboratories, and sick-rooms for bodily illness would be at the main hospital. These measures, Col. Russell claimed, would reduce by one-half the number of alleged incurables at the main headquarters hospital, and would so change its character that patients and their relatives would be willing and even glad to have the modern psychiatric treatment available at such centres. He agreed that the pride of administrators in the size of their large institutions would have to be combated, also that dispersal of units can show some economic and administrative disadvantages, but the making of the mental hospital acceptable to the public mind seemed to outweigh these disadvantages.

Industry and Psychiatric Research

At the same meeting of the Mental Hospitals Association there was an interesting paper by Dr. J. R. Murray, medical superintendent, St. George's Hospital, Morpeth, who urged the development of a liaison between psychiatric research centres and industrial undertakings and the industrial health service. Research, he said, was the key to the future of psychiatry. Such research as had been done in the past, often painstaking and sometimes brilliant, had suffered by its separation from the main stream of medical research, and had lacked the critical and stimulating contact with university thought which it was hoped would be brought about in a new mental health service. Research into positive mental health was required as much as, or more than, research into the negative aspects of the problem. The work done in the Services by way of personnel selection, with its intelligence, temperament, and aptitude tests, had foreshadowed a wide field for vocational guidance and industrial psychology.

Medico-Legal

ANTI-VIVISECTION SOCIETIES NOT CHARITABLE BODIES

In the King's Bench Division on July 27 Mr. Justice Macnaghten allowed an appeal by the Crown in the case of the Commissioners of Inland Revenue *v.* the National Anti-Vivisection Society, on the ground that in his view the society was not entitled to exemption from income tax as a charitable body.

The hearing of the appeal occupied two days. In his considered judgment Mr. Justice Macnaghten said that the society had claimed exemption on the ground that it was a body of persons established only for charitable purposes. The Commissioners for Special Purposes of the Income Tax Acts had considered themselves bound by a decision given in 1895 by Mr. Justice Chitty in the case of Foveau Cross *v.* the London Anti-Vivisection Society, in which the society was held exempt from income tax. The question, said his lordship, was whether the Special Commissioners were right in holding themselves bound to follow Mr. Justice Chitty's clear decision that a society for the total suppression of vivisection was a charity. He accepted the facts, which had been found by the Commissioners, that the main object of the society was the total abolition of vivisection, and held it conclusively proved that the discontinuance of experiments on living animals would be a serious obstacle in the way of obtaining further medical knowledge of benefit to the public. That being so, it seemed to his lordship plain that the society had failed to establish that it was a charity beneficial to the community. In his view the Commissioners ought to have rejected the claim to exemption from tax under Sect. 37 (1) of the Income Tax Act, 1918.

We understand that the National Anti-Vivisection Society is appealing against the judgment and is being supported by other bodies of a similar description. Certain of these, such as the Animal Defence and Anti-Vivisection Society, make anti-vivisection only one of their objects, and carry out many-sided work for the protection of animals in general, such as hospitals, homes, and aid posts, which would be regarded as charitable on any reading of the word, and if the judgment is sustained some means will have to be found, presumably, of separating for tax purposes the anti-vivisection propaganda of the society from its other activities.

S. Nesbitt, P. F. Mark, and H. M. Zimmermann (*Arch. intern. Med.*, 1945, **22**, 601) record a case of Kaposi's disease (disseminated visceral idiopathic haemorrhagic sarcoma) which was of special interest because of the involvement of the thyroid gland and brain, of which there has not been a previous example recorded.

Correspondence

Epidemic Diarrhoea

SIR,—I have read with great interest the leading article on epidemic diarrhoea (Aug. 11, p. 189). Early in 1941 (April 12, p. 554) I published jointly with Major (then Captain) D. J. Davies a preliminary report on gastro-enteritis at a large Army centre. This clinical work was done in conjunction with Dr. Robinson, lecturer in bacteriology, Liverpool University, then in charge of the E.M.S. Laboratory at Conway, who was at that time not allowed to publish the article jointly with us by the E.M.S. regulations then in existence. This preliminary report, which at the time created a little interest, as shown in the letters sent to us and to the *Journal*, was to have been followed by another report based on our further clinical work and the findings of Drs. Scott and Griffith, of the Ministry of Health, who were working with the specimens of blood we sent to them. This work they informed us was most promising, and they had transmitted the infection through several series of monkeys. Unfortunately, they were both killed in the May, 1941, "blitz" on London, and all their papers were lost. At the time, if I remember rightly, they thought that they had discovered a virus which was definitely the cause of the epidemic gastro-enteritis, and they were in process of identifying the strain.—I am, etc.,

Llanelly. A. H. D. SMITH.

Amoebiasis

SIR,—In the *Journal* of April 28 (p. 613) it is reported that Dr. Morgan asked the Secretary of State for the Colonies for information about amoebic dysentery in the South and East African Colonies from below Egypt to the Cape. In South Africa, Natal is generally considered to be a hotbed of the condition. In one Durban African hospital alone there were over 1,200 proved cases in 1944. Other hospitals and private nursing homes have the same story.

The disease takes a much more virulent form in Africans than in Europeans; the Indian population is relatively immune. In the African there is an acute dysentery with prostration and dehydration. On examination, the stools are literally teeming with active haematophagous trophozoites, as many as 100 amoebae having been counted in a single low-power field. The cellular content of the stool is that of an acute bacillary dysentery. When it has been possible to culture the stools organisms of the dysentery group are very seldom found. In Europeans here, however, the disease is more chronic, with an accent on the remoter less specific effects of the organism. The Indians seem to have developed a symbiosis with the amoeba, though they do not show a high incidence of the condition.

The incidence of the more acute form in the native population is contrary to usual teaching, and rather suggests that this may be a "new" disease to them. This is borne out by the low incidences of this condition reported elsewhere, both in other South African provinces and in the Parliamentary note referred to.

Dietetic influences may also play a part in determining the difference in the condition found in Africans and in other races here in Natal. The natives have a predominantly carbohydrate diet, and it may be that this predisposes to an acute form of the condition, as it does in dogs. There may, of course, be an associated avitaminosis. The importance of the dietetic factor is also illustrated in the fact that there has been a marked increase in the condition during the war years, when the native urban population have been deprived of their meat, which constituted their main supply of protein. It is a remarkable fact that there has also been, during the same period, a phenomenal increase in the incidence of tropical ulcer in the same people, though this condition is also found in the Indian.—I am, etc.,

Durban. R. ELSDON-DEW.

Treatment of Infective Hepatitis

SIR,—May I use the medium of your columns to bring forward some tentative suggestions for the treatment of infective hepatitis.

It is established that the disease is almost certainly due to a virus. It seems a possibility that the latter may require methionine for its own economy. The liver would thus be deprived of an important metabolite and necrosis would ensue. The administration of methionine while the virus is still active might encourage further growth of the infective agent, in addition to stimulating recovery of the liver. These two effects are mutually antagonistic, and hence the apparent ineffectiveness of methionine in treatment. On occasion the amino-acid might even be dangerous, in so far as stimulation of the virus could be greater than that of the liver and so lead to further necrosis. This would seem to be borne out by the unfortunate experience of Higgins (Higgins *et al.*, 1945). This may, however, have been pure coincidence. There is a possibility that the virus does not itself require methionine, but is capable of rendering that compound unavailable to the liver. The above remarks will apply equally well to the use of choline (Richardson and Suffern, 1945). This substance would seem to increase the methionine/cysteine ratio (György and Goldblatt, 1940). In this way it acts merely by making more methionine available to the liver.

The primary problem of treatment is, therefore, to destroy the virus. Administration of methionine might then be of some use in accelerating recovery. The question would seem to be one of immunity. On these grounds the early administration of γ-globulin to established hepatitis might be indicated. It has already been shown in the U.S.A. to have marked prophylactic value in this disease.

On the other hand methionine apparently speeds recovery from arsenical hepatitis. This apparent anomaly is capable of explanation by assuming that the virus of this disease sensitizes the liver to the action of arsenic in therapeutic dosage. This is the exact converse of what is generally thought—namely, that arsenic sensitizes the liver to the virus. The metalloid is known to produce necrosis by interference with the thio-amino-acids of the liver cell. This is limited by the amount of arsenic given and, therefore, can be overcome by therapeutic administration of methionine, or possibly choline.

Finally, it is important to stress the possible value of γ-globulin in the prophylaxis of homologous serum jaundice as well as that of arsenical hepatitis.—I am, etc.,

A. L. LATNER,
Wirral, Cheshire. Capt., R.A.M.C.

Effort Syndrome in West African Soldiers

SIR,—I have just had the opportunity of reading Major M. D. W. Elphinstone's criticism (July 28, p. 134) of my article on effort syndrome in the West African soldier (June 30, p. 908). While I maintain that the facts and figures given in the article do lend support to the conclusion arrived at, it cannot be denied that the proportion of Christians to non-Christians in the 40-bed surgical ward of the hospital in which the cases were recorded do suggest that this hospital did not serve its quota of combatant units with their predominantly Mohammedan and pagan personnel. I am grateful to Major Elphinstone for raising the matter, for the true explanation cannot be deduced from the article.

In fact, during the first ten months of the year in which this investigation was undertaken the hospital did serve units of all arms in the Gold Coast, including the infantry. Indeed, if cases of effort syndrome were to be found in non-Christians, this hospital was better placed to receive them than any other medical unit in the Gold Coast. During the last two months of the investigation, however, troop movements from the hospital area caused a considerable decrease in the proportion of non-Christians admitted to the hospital, and this was the state of affairs when the count was taken in the surgical ward.

Without doubt figures more favourable to my case could have been obtained by selecting them from the ward reports of a few months previously, but this might have savoured of "cooking the accounts." I should add that in the first ten months eleven of the twelve cases recorded were seen.

Major Elphinstone also suggests that if a non-Christian soldier with effort syndrome did reach a "sympathetic" R.M.O. the latter would probably fail to diagnose the condition, because he would have the same difficulty as I had in getting *en rapport* with such a patient. I cannot agree with this. The R.M.O.s of the combatant units in the hospital area were, I am glad to say, sympathetic, but not soft, and some of them had had very considerable experience in dealing with the West African native. Furthermore, the diagnosis of effort syndrome rests on the presence of definite symptoms and signs. The Northern Territory man is able to complain directly, or through interpreters, of such symptoms as pain in the chest, headache, inability to take exercise, or anorexia when they are due to organic disease: why not when they are manifestations of effort syndrome? The doctor need not be in mental harmony with his patient to make a diagnosis of effort syndrome. On the other hand, this is essential if he is to discover *why* (not whether) the man has developed the syndrome, so that even with English-speaking Africans "no attempt has been made to diagnose the psychological abnormalities underlying these cases" in the paper.—I am, etc.,

Brompton Hospital, London, S.W.3. DERYCK L. H. GODDARD.

Breast-feeding

SIR,—Dr. R. O. Barber (April 21, p. 566) clings tenaciously to the *older concepts* of breast-feeding, the teaching of which has, in my experience, only helped to confuse and confound mothers still further.

It is refreshing to note the observations made by Dr. M. Pallot (May 19, p. 714) and endorse his remarks about the care of the nipples. For over ten years I have advised mothers to apply gauze soaked in cod-liver oil to the nipples as a prophylactic and therapeutic measure against cracking, with most gratifying results. Unlike most of the other applications prescribed, cod-liver oil is safe, sound, and efficient. Should the baby happen to lick some of it off it can only do good.—I am, etc.,

Johannesburg. M. WITKIN.

Day Nurseries

SIR,—When I wrote to you on the question of mothers with young children going out to work I mentioned three people concerned. I had in mind a fourth—the well-intentioned "advocate and supporter" of day nurseries—but I did not mention him because I wished to lure him into print. Sir Drummond Shiels and Dr. L. Stuart Woolf (Aug. 11, p. 198) have duly obliged. What do their arguments amount to?

Sir Drummond sets out the reasons which have led to the establishment of day nurseries, and as statements of fact I accept most of them. I must, however, protest when, after stating quite correctly that the arrival of the first baby brings a tie which makes it difficult for husband and wife to go out together, he goes on to make the romantic suggestion that this "first break in married happiness" is averted by the existence of the day nursery. If all the adult males of the country were night watchmen there might be some point in the suggestion, but as in fact father's return from work usually coincides with the closing of the day nursery this delightful picture will not bear examination.

Dr. Woolf accuses me of "half-truths." I wrote from twenty-five years' experience of industrial practice, and I can only say that I find his statements not half-true but utterly fantastic. What proportion of fathers are in prison, or have deserted their wives, or own one-man businesses? As for mothers in lodgings, I have never come across one (she can't afford it: what is she going out to work for?); and if the child is so happy at the day nursery why is he so pleased when his mother comes to take him away?

The essential difference between myself and my critics is to be found in the first paragraph of Sir Drummond Shiels's letter, where he speaks of "misunderstanding . . . of the motives of those who advocate and support day nurseries." He is wrong. I do not question their motives; I do not doubt that their road is paved with good intentions; but where does it lead to?

In my last letter I suggested that encouraging young mothers to go out to work (which is what we do whenever we put up a day nursery) not only is bad for the individuals concerned but also is a definitely anti-social policy. As surely as "Speenhamland" it involves a subsidy in aid of wages, with this difference—that whereas "Speenhamland" made for a rise in the birth rate, this makes for a fall. Is it not highly significant that neither of my critics has ventured to take up the population issue? This is all the more regrettable because Sir Drummond's letter shows that he, at any rate, appreciates something of the problems involved, yet the shock of my letter has so confused him that he ends by begging me to agree to the temporary continuance of some day nurseries. I never proposed that we should celebrate "VJ-Day" by shutting up a single one of them; what I said was that every one was a blot on our civilization. So is every slum, but not one of us would propose to pull down a single slum at this moment; even a slum house is better than no house. Now slums represent the nineteenth-century attempt to meet the needs of underpaid workers, and day nurseries one of the twentieth-century's attempts to tackle the same problem. Are either of them the best that we can do?

We know that elected local authorities and the Ministry of Health are (historically) young, and, like many young children, are fond of building with bricks; but are they not old enough to give up saying: "Look what I've done; isn't it clever?" and to say instead: "Let's look what we've done: is it good enough?"—I am, etc.,

Wandsworth. F. GRAY.

Toxic Properties of Sting-ray's Sting

SIR,—I read with special interest Dr. Muir Evans's letter on the toxic properties of the sting-ray's sting (Aug. 4, p. 165), as I have personal experience of being stung both by the sting-ray in Cornwall and by a jelly-fish in the Suez Canal during the 1914–18 war. By an odd chance the sites of stinging were very similar in both cases to those described in the letter.

I can confirm the excellent description of the wound and progress of symptoms from the sting of the ray. It appears to me, however, that some of the symptoms in these cases—i.e., vomiting and constipation—might be attributed to the morphine, as these symptoms are common with this drug. It is also possible—and this is the point which appears to me of interest—that the toxic properties of the sting may render the victim unusually sensitive to the effects of morphine. I had no morphine on either occasion and did not vomit or have severe constipation. It would be interesting to know whether controls who had the misfortune not to receive morphine for the relief of their pain, escaped also the vomiting and constipation.—I am, etc.,

Camborne. R. H. BLAIR.

Recommendations of the Goodenough Report

SIR,—I find it difficult to appreciate Sir Ernest Graham-Little's objection (Aug. 11, p. 199) to a reform which would restore the London M.B., B.S. degree to its rightful place as a qualifying degree. I think most medical practitioners who have been students at any of the London medical schools would agree that a reform in teaching methods and examinations is long overdue. The practice of leaving a student in his clinical years to amuse himself for three years before taking his finals is hardly in keeping with any reasonable system of education.—I am, etc.,

Bradford. F. J. FISH.
Capt., R.A.M.C.

S. L. Robbins (*Arch. intern. Med.*, 1945, **75**, 280) records three cases of cerebral abscess complicating congenital septal defects of the heart, which brings the total number of such cases to 26. In only three of the cases on record was an ante-mortem diagnosis made and surgical drainage instituted.

Obituary

ROBERT ALFRED WORTHINGTON, O.B.E., F.R.C.S.

The death of Mr. Robert Alfred Worthington of Exeter removes one of the best-known surgical specialists in the West of England and also a man of more than local fame as an accomplished water-colour painter.

Though he spent nearly the whole of his professional life in Devonshire, Worthington was a Yorkshireman, born at Saltaire 67 years ago. Both his father and mother were artists—his father was also a mathematician and physicist of some distinction—and the son inherited their gift. At Rugby he won a prize for drawing, a subject not much esteemed in public schools in those days, and he was told that it was a pity he could not get a prize for something serious. From Rugby he went to Clare College, Cambridge, and, adopting medicine as his career, proceeded to the London Hospital, qualifying in 1904. For a time he was clinical assistant in the out-patient department at the East London Hospital for Children, and assistant director, under Prof. H. M. Turnbull, at the Pathological Institute of the London Hospital. While serving in the latter appointment he was responsible for the first and second volumes of the archives of the Institute, and in their production he showed his skill not only in editorship but in design and illustration, setting so high a standard that no one, apparently, was found to emulate him after he left the London Hospital, and no more annual volumes were issued.

In 1909 he took his F.R.C.S., and afterwards studied for a time in Berlin, where he acquired experience in the endoscopic methods then coming widely into use. In 1911 he was appointed surgical registrar and assistant pathologist to the Royal Devon and Exeter Hospital, and thus began his connexion with Devonshire which continued until his death. Presently he specialized in otology and laryngology, and in 1914 he became surgeon-in-charge of the ear, nose, and throat department at his hospital. He still continued to do general surgery as well, and during the first European war, when he was in command of the 2nd Exeter General Hospital, he was responsible for the general surgery there as well as for his own specialty. After the war he devoted himself exclusively to ear, nose, and throat work. He became aurist to the West of England Institute for the Deaf and Dumb and aurist and laryngologist to a number of hospitals in his county. For a time he was lecturer in vocal anatomy and physiology to the London Academy of Music, and was co-author of a book entitled *The Mechanics of Voice Production*, illustrated by a number of *x*-ray pictures of his own throat during the various phases of speech. He himself had suffered in early life from a speech defect, which he overcame by his own efforts until it was no more than a rather attractive hesitancy, and to help others similarly placed he wrote a thesis on stammering and its treatment. His reputation stood high among his fellow specialists, and he was made vice-president of the Section of Otology of the Royal Society of Medicine.

In his earlier life Worthington's chief recreations were music and hunting, but during the last twenty years he developed his native skill with the brush and devoted much of his leisure to water-colour. It was said that he never undertook a professional or recreational journey without his painting materials, never knowing what subject might catch his observant eye. He was not only a painter, but a discerning critic and collector, an expert on the work of the English school of water-colour. At a time when it was thought that Exeter was safe from air raids he stored in the basement of his house in Southernhay many valuable pictures, the property of his London friends. In May, 1942, Exeter was the target of a "Baedeker raid" and Worthington's house was set on fire by incendiary bombs. He made superhuman and successful efforts to remove to a place of safety the treasures of which he was in charge, but his house was destroyed, and with it perished most of his personal collection and his own work. He never quite recovered from the shock of that experience, and during the last eighteen months his health caused serious concern to his many friends. He died at Honiton after an attack of cerebral haemorrhage.

Worthington married Miss Evelyn Bankart, sister of Mr. A. S. Blundell Bankart, the London orthopaedic surgeon. She survives him, with one daughter.

C. E. M. JONES, M.B., B.CH.

The news of Dr. C. E. M. Jones's death on Aug. 3 at Alton, Hants, was received by his many friends with great sorrow.

Charles Edward Mellersh Jones was born on May 9, 1881. He was educated at Eggars Grammar School, Clifton College, and King's College, Cambridge, and received his medical training at Guy's Hospital, graduating M.B., B.Ch.Cantab. in 1908. He started his medical career at Alton with his father, the late Dr. G. M. Jones, and at the outbreak of the 1914 war was M.O. of the 4th Battalion of the Hampshire Regiment. In October, 1914, he was sent with his battalion to India, and in the following March went to Mesopotamia. After serving through all the operations of that campaign he was taken prisoner on the fall of Kut. He was kept a prisoner in the hands of the Turks in the Taurus Mountains, and gained his freedom only after the cessation of hostilities.

On his return to England he joined the resident medical staff of the Lord Mayor Treloar Hospital, and as chief assistant to the late Sir Henry Gauvain a loyal partnership and deep friendship was formed between the two men who did so much for the hospital and for its patients. This happy partnership lasted well over 20 years, and was ended only this year by the death of Sir Henry Gauvain, to whom Dr. Jones was the natural successor as medical superintendent. Sir Henry repeatedly acknowledged the debt he owed to his old friend and the part he played in all the activities of the hospital. His knowledge of surgical tuberculosis in children and adolescents in particular was profound, but, with so many chronic cases in the wards, a cheerful and optimistic atmosphere is almost as important as medical skill, and in creating and preserving this atmosphere these two men were supreme. He was a gifted teacher, as many a student, taken by his chief in a party to visit the hospital, has gratefully testified.

Jones was deeply loved by all, both patients and staff. On innumerable occasions a whispered word and a fatherly caress from him brought smiles instead of tears to the face of a little patient. Jones was invariably cast for Father Christmas, a part his enthusiasm for amateur theatricals enabled him to fill with unusual success.

The young doctors on joining the staff, without exception, rapidly acquired a deep respect and affection for "Jonah." His unfailing courtesy to all whose duty took them to the hospital, his love of good company, and his fund of good stories made him everybody's friend. He was an excellent boxer in his younger days, and as a fast bowler assisted the Alton XI on many occasions. As a batsman it was either six or nothing. He will be sadly missed by his dogs as well as his host of friends.

H. A. T. F.

Medical Notes in Parliament

New Government's Programme

The King's Speech, read to both Houses of Parliament on Aug. 15, promised increase by all practicable means of the number of houses available in town and country. It announced that Parliament would be asked to approve measures to provide a comprehensive scheme of insurance against industrial injuries, to extend and improve the existing scheme of social insurance, and to establish a national health service. A promise was given that Ministers would keep in being and extend the new food services for the workers and for mothers and children which had been established during the war. Education reforms already approved would be brought into practical effect at the earliest possible date.

Speaking in the Debate on the Address on Aug. 16 Mr. ATTLEE said there was a world shortage of meat, fats, and sugar, which could not be overtaken because the food was not there. It would be unwise to expect that the end of the war with Japan would materially affect the position for some months. Nothing the Government could do in new housing construction would substantially alleviate the serious position which would arise this winter. For the present, direction of the housing campaign would rest with the Minister of Health in England and Wales, and in Scotland with the Secretary of State. The Government intended to introduce legislation providing a comprehensive scheme of industrial insurance, and to expedite the setting up of a national health service.

Negotiations with Medical Profession

When the debate was resumed on Aug. 17 Mr. GREENWOOD said the Government's duty was to proceed with the National Insurance Scheme and follow that with the health plan. That course was forced on the Government by the terrible muddle in which the health plan had been left by the late Minister of Health (Mr. Willink). The White Paper on the Health Services had not gone as far as the Labour Party would have liked, but had been generally accepted by the House. Yet after undue delay the fact had become known that Mr. Willink, behind the backs of everyone else, had opened discussions with the British Medical Association.

Mr. WILLINK pointed out that Mr. Tom Johnston, a member of the Labour Party, had been associated with him in these discussions.

Mr. GREENWOOD said that when the secret discussions closed the late Government had not been committed in any way. The present Government would not start where these negotiations had finished. It must go back to the White Paper, and its task would be more difficult because of the unnecessary concessions which Mr. Willink had made. Mr. Greenwood added that Mr. James Griffiths, the Minister of National Insurance, was pressing on with further details of the social insurance measure. This looked like becoming one of the longest Bills ever seen in the House of Commons, but should be in the hands of Members when they resumed next year.

In the House of Lords on May 16 Viscount ADDISON, speaking as Leader of the House in the Debate on the Address, said the health and social insurance proposals were based in the main on those which recently had been produced and agreed to. There would have to be, on the health side, departures from decisions which Mr. Willink seemed to have reached *in camera* with various parties but which had not been disclosed. He left it at that.

Universities and Colleges

UNIVERSITY OF GLASGOW

It is announced that in response to the invitation of leading representatives of the University Liberal, Scottish Nationalist, and Socialist groups, and also of leading Independents, Sir John Boyd Orr, M.D., F.R.S., who returned to Parliament after the General Election, has accepted nomination as Independent Progressive candidate for the Lord Rectorship of Glasgow University.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

POSTGRADUATE SURGICAL TEACHING

The Royal College of Surgeons maintains a Library, Museum, and Laboratories for the use of medical graduates from all parts of the world. These facilities are available to Fellows and Members of the College by right, but they have also been made open, on suitable introduction, to graduates of medicine who are not Fellows and Members. They are also open to undergraduates, and a large number of students have used the Library during the war, though unfortunately the museum specimens have not been available. It is hoped that specimens will be on exhibition again at an early date.

In addition to the above facilities short courses of instruction have been held each year on the contents of the Museum—the Arnott Demonstrations in Anatomy by Prof. Cave, and the Erasmus Wilson Demonstrations in Pathology by pathologists and surgeons appointed each year. These classes have been attended by large numbers of graduates and undergraduates. In addition, the Arris and Gale and the Hunterian Lectures provide opportunities for the presentation of original work in anatomy, physiology, pathology, and surgery.

In recent years the Professors of the College have given an increasing number of lectures, and it has now been decided that two regular courses shall be given each year on anatomy, pathology, and applied physiology—by Professors Wood Jones, A. J. E. Cave, J. Beattie, and R. A. Willis. These courses will deal with the subjects of the Primary examination for the Fellowship. They are not designed, however, to provide complete and comprehensive instruction in these subjects but to deal with such fundamental aspects as shall be selected from time to time. They must not be regarded as classes specially arranged for the examination; but they are so planned as to be helpful to candidates, and also to practising surgeons, by dealing with recent advances in these subjects and their practical application. At present these courses are open to all medical graduates without fees, but later on fees may be charged to those who are not Fellows or Members of the College.

The Council has also decided to provide instruction in surgery by arranging courses of lectures each year, designed to assist those who are engaged in specialist work, and those who are preparing themselves for the Final examination for the Fellowship of the College. The lecturers will be chosen each year from a panel of teachers, and the subjects dealt with will cover a large range of general and specialist surgical work. The lectures will be arranged in two courses, one in the spring and one in the autumn. Lectures will be given at 5 p.m. on several days a week, but there will always be one of special interest on Thursdays. The lectures will be free to Fellows and Members, but others desiring to attend the courses will be required to pay a small fee.

In addition to the facilities provided and the lectures and demonstrations outlined the College awards several prizes for meritorious work as well as many Fellowships for those who desire to engage in practical work in the Museum and Laboratories or to devote some time to research. The awards open are:

1. *For Undergraduates.*—Begley Prize in anatomy and physiology, £16 10s. *Jenks Scholarship, £27 p.a. for five years. Macloghlin Scholarship, £90 p.a. for five years.

2. *For Graduates.*—Hunterian Professorships, 12 each year, £10 10s. Arris and Gale Lectureships, three each year, £10 10s. Charles Tomes Lectures, two each year, £10 10s. Every four years alternately with Liverpool University and the Liverpool Medical Institution—Robert Jones Travelling Fellowship, £250. Leverhulme Scholarships—two of £500, usually for three years. Bland-Sutton Research Scholarship, £300. Prophit Research Studentships, two of £500. *Streatfeild Research Fellowship, usually £250 for three years. *Mackenzie Mackinnon Research Fellowship, three of £250 or according to circumstances.

3. *Awards for Special Meritorious Work.*—Bradshaw Lecture, £27. Thomas Vicary Lecture, £10 10s. Robert Jones Lecture, £30. Moynihan Lecture, £125. Lister Medal, £500. Cartwright Prize, £100. Walker Prize, £100. Jacksonian Prize, £18 5s. John Hunter Medal and Triennial Prize, £50. John Tomes Prize £22. Hallett Prize, £5 5s.

* Jointly with the Royal College of Physicians.

The Services

Acting Surg. Lieut.-Cmdr. G. R. Nicks, R.N.V.R., has been appointed O.B.E. (Military Division) for excellent service in the maintenance of law and order in Greece during the period of the Civil War, 1944–5.

Temp. Surg. Lieut. M. Sherrard, R.N.V.R., has been mentioned in dispatches for distinguished service, efficiency, and zeal while serving in one of H.M. ships in the clearance of the Aegean and the relief of Greece during the period 1944–5.

Major W. H. Cavan and Major (Acting) J. I. Matas, R.C.A.M.C., have been mentioned in dispatches in recognition of gallant and distinguished services in Burma.

Medical News

A meeting of the Medical Society of the L.C.C. Service will be held at the County Hall, Westminster Bridge, S.E., on Wednesday, Sept. 5, at 4.30 p.m., when a discussion on subarachnoid haemorrhage will be opened by Dr. Barling, Dr. Bratton, Dr. Jacobs, and Dr. Simmons.

The 104th annual meeting of the Royal Medico-Psychological Association will be held at 11, Chandos Street, London, W.; on Wednesday and Thursday, Sept. 5 and 6, beginning at 10.30 a.m. each day. On Sept. 5 there will be a discussion on "Ageing and Senility," with contributions by Dr. Aubrey Lewis on a major problem of psychiatry; by Miss H. Goldschmidt on social aspects and Mrs. Margaret Eysenck on psychological aspects of ageing and senility; and by Dr. Derek Richter on some biochemical changes in senility. The annual dinner will be held at the Savoy Hotel at 7.30 p.m. On Sept. 6 the president, Lieut.-Col. A. A. W. Petrie, R.A.M.C., will open a discussion on "The Future Organization of the Psychiatric Services," and this will be followed by a discussion on the revision of the constitution and by-laws of the Association.

On and after Aug. 27 the permanent address of the Tavistock Clinic will be Nos. 2–4, Beaumont Street, London, W.1 (formerly the Duchess Nursing Home), although it will be closed to patients until Sept. 10. The Clinic's pre-war premises at Malet Place, W.C.1, were completely destroyed by enemy action in 1941, and it has been functioning since then in a wing of Westfield College.

Among the eight Chinese representatives of different professions who are visiting this country just now as guests of the British Council is Dr. Wang Ging-Hsi, the physiologist and director of the Institute of Psychology of the Academia Sinica. He will be here for three months.

A provincial meeting of the Tuberculosis Association will be held at Bristol on Thursday, Friday, and Saturday, Sept. 6, 7, and 8. The programme is as follows: Sept. 6, 12.30 p.m., council meeting; 2.15 p.m., opening address by Prof. R. H. Parry; 3 p.m., paper by Dr. William Stobie, "Tuberculosis and the Eye"; 5 p.m., annual general meeting. Sept. 7, 9.30 a.m., paper by Dr. P. E. W. Edwards, "Treatment of Primary Tuberculosis in Adults"; 10.30 a.m., discussion, "Chemotherapeusis in Empyema," to be opened by Mr. J. E. H. Roberts and Prof. R. S. Pilcher; 2.30 p.m., visit to Ham Green Sanatorium, where there will be demonstrations by Dr. J. Campbell Faill and Mr. R. Belsey; 7 p.m., annual dinner. Sept. 8, 9.30 a.m., paper by Lieut.-Col. W. H. B. Bull, N.Z.A.M.C., "Tuberculosis in Allied Prisoners of War"; 10.30 a.m., papers on tuberculosis in Europe during the war, (1) Prof. E. Rist, "Tuberculosis in France," (2) Dr. Henri Durieu, "Tuberculosis in Belgium," (3) Dr. Van Den Berg, "Tuberculosis in Holland." All the meetings will be held at Wills Hall, Bristol, with the exception of that at Ham Green Sanatorium.

The Sheffield Radium Centre has received a gift of £10,000 from Mr. James Morrison for research in radiotherapy of cancer. The fund, which is to be named after the donor's brother David, will be used to establish a radiotherapy research department at the Centre for investigation of new methods of irradiation, for which supervoltage *x*-ray equipment and a radium beam unit will be installed. The trustees of the fund, nominated by Mr. Morrison, are Dr. Sydney Atkin, Mr. G. W. Blomfield, medical director of the Centre, and Mr. P. M. Osborn, deputy chairman, Royal Sheffield Infirmary and Hospital.

The Board of Management of the Marie Curie Hospital for Cancer and Allied Diseases (Fitzjohn's Avenue, London, N.W.3) has received a gift of £2,000 from Lord Nuffield towards the Re-establishment Fund, to endow a bed. £250,000 is required for the rebuilding of the hospital, which was destroyed through enemy action early last year.

The Sterilized Catgut Manufacturers' Association has been formed to protect and to advance the interests of the members, and to negotiate with Government Departments and others on all relevant matters.

The Council of the Royal Society of Medicine has decided to continue, as part of the Society's normal services, the Visitors' Reading Room, which for the past seven months has provided non-Fellows with accommodation and library facilities.

Dr. M. Rana has been appointed a Nominated Indian Unofficial Member of the Legislative Council of Kenya Colony.

Dr. George Riddoch has been appointed honorary consulting neurologist to the Ministry of Pensions.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* there were 391 fewer notifications of measles than last week, but 98 more of dysentery.

Although the total notifications of whooping-cough remained practically constant, there were considerable local fluctuations, the largest being an increase of 54 in Warwickshire. The notifications of diphtheria were 10 fewer than last week's record low level. Monmouthshire, with a rise of 82, was the only exception to the general drop in the incidence of measles.

Dysentery was more prevalent than for the past six weeks. No fresh outbreaks of any size were reported, but there were large increases in Oxfordshire, from 8 to 27, and in Lincolnshire, from 11 to 62 (Scunthorpe M.B. 50). The other high totals were Lancashire 37, London 30, Middlesex 21, Surrey 20, Yorks West Riding 13, Warwickshire 13, Buckinghamshire 10.

In *Scotland* notifications of scarlet fever rose by 26, there being 43 more cases in the western area than in the preceding week; in all other areas the incidence fell. There were 21 fewer notifications of dysentery, the largest return being Glasgow C.B. 17.

In *Eire* the incidence of infantile diarrhoea and enteritis, falling by 52, was the lowest recorded for three months: 17 deaths were registered from this cause in Dublin C.B. A record low level of diphtheria, 50 cases, resulted from the fall of 22 in the notifications. Whooping-cough reverted to the level of the preceding weeks, with 23 fewer notifications.

In *Northern Ireland* notifications of scarlet fever rose by 8. The incidence of other infectious diseases tended to fall.

Week Ending August 11

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 937, whooping-cough 936, diphtheria 346, measles 1,681, acute pneumonia 251; cerebrospinal fever 33, acute poliomyelitis 16, dysentery 300.

No. 31

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 4.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Purpura

Q.—*A woman of 64 noticed that she was bruising easily. Some 3 weeks after, purpuric spots began to appear in skin and mucous membranes, followed by epistaxis. Blood transfusions and splenectomy were carried out successfully, one moderate and two small attacks of epistaxis occurring at regular intervals post-operatively (7–10 days). Transfusion (fresh blood) was given after each epistaxis. Approximately 3 months after splenectomy purpuric spots are reappearing in skin and mucous membrane. The most recent blood count shows platelets 150,000 per c.mm. Is capillary weakness a factor as well as a low platelet count? Are further, regular attacks of purpura to be expected? Are blood transfusions necessary? If so, on what indication? Has focal infection any connexion, and, if so, where? What is the general prognosis? Which books are the best for reference?*

A.—It is unusual for essential thrombocytopenia to occur at this age. Of a series of 271 cases collected by Wintrobe and co-workers (*J. Amer. med. Ass.*, 1937, **109**, 1170) only 10 were over 50 and none apparently over 60 years of age. The data given are inadequate for a differential diagnosis, but the possibility should be considered that the thrombocytopenia is secondary to some other malady, such as aplastic anaemia or leucopenic leukaemia. In essential thrombocytopenia capillary weakness is a factor, and the capillaries do not retract normally on injury. This has been demonstrated by R. G. Macfarlane (*Quart. J. Med.*, 1941, **10**, 1). Improvement follows splenectomy in about 80% of cases. It is not always complete and immediate, and there would still be a prospect of further improvement in the present case if the diagnosis is correct. Nor is recovery always permanent, relapses occurring in perhaps 10% of cases. When the disease is chronic, blood transfusions are really only of value for the anaemia, and there is no specific remedy. Focal infection is rarely of importance, but an allergic reaction, particularly to the drug sedormid, is always worthy of inquiry. The over-all mortality of essential thrombocytopenia in females after puberty has been given as 40% (Evans and Perry, *Lancet*, 1943, **2**, 410). Further reference may be made to the following books: *The Hemorrhagic Diseases*, by A. J. Quick, Springfield, Ill., 1942; and *Clinical Hematology*, by M. W. Wintrobe, Philadelphia, 1942.

Apex Beat of Heart

Q.—*Can the apex beat of the heart of normal size be felt in the mid-axillary line when the patient is lying fully on his left side, the apex beat not being palpable in the erect or dorsal position?*

A.—The normal apex can be felt in the left axilla when the patient lies on the left side—perhaps not quite so far as the mid-axillary line. The apex is then well against the chest wall; whereas in the upright position obesity or emphysema might obscure it, or the vertical heart might have an apex beat near the mid-line.

Bilateral Bronchiectasis

Q.—*A woman of 30, who had a bad bronchial catarrh initiated by noxious fumes in a poison-gas factory some time ago, has been left with a number of very small bronchiectases scattered about the bases of both lungs. Is there anything to be done about it?*

A.—Bilateral bronchiectasis is not necessarily unsuitable for surgical treatment; indeed, bilateral lobectomies have been done with excellent results. The operations are, however, most likely to be successful in children and young adults. In the case of a woman of 30 bilateral intervention would be justified only if the symptoms were very grave or the amount and character of the sputum rendered life intolerable. Operation on one side only is liable to be disappointing. Quite apart from this, it is doubtful if the type of disease present in this patient is suitable for operation. The causal agent and the description of "a number of very small bronchiectases scattered about the bases of both lungs" suggest the probability of an associated chronic bronchitis and emphysema, which would definitely be unfavourable.

Treatment should consist of postural drainage and breathing exercises, expiratory as well as inspiratory; if much infection is present, penicillin given by inhalation should be considered.

Drug Treatment of Cancer

Q.—*Can you recommend any form of drug treatment likely to benefit a man of 54 with inoperable carcinoma of the colon and secondary deposits in the peritoneum? Liver normal. Colostomy has been performed to relieve the obstruction. At the moment his general health is good.*

A.—It is certainly not possible to "recommend" any form of drug treatment here, in the sense that one is justified in expecting benefit as a reasonably frequent sequel; there is at present no such justification. On the other hand, the question raises an issue of general interest, and is probably dealt with best from this wider point of view. Until comparatively recently the attention of most students of cancer was quite rightly held by the cancer cell's autonomy and independence, and by its refractoriness to environmental changes of many kinds, including those which can be brought about by the action of drugs. On this basis there developed a confirmed scepticism—still only too well merited so far as cancer in general is concerned—as to the feasibility of affecting malignant growth by chemical agents which do not at the same time seriously interfere with the normal processes of growth and repair. Within the last few years, however, this rather extreme viewpoint has become modified, through the knowledge that both the growth characteristics and the histological structure of many tumours can be materially influenced by hormonal agents, and especially by oestrogenic compounds, both natural and synthetic—a practical example being the useful control of prostatic cancer which has been achieved in this way. Carcinoma of the prostate is probably as exceptional an example as it is a favourable one, but it is a curious and still unexplained fact that in a small proportion of other types of cancer—for example, a low percentage of cases of carcinoma of the breast, and random examples of other cancers which one would not classify as possessing any special hormonal susceptibility of this kind—oestrogen therapy does in fact have some effect: e.g., local alterations in the tumour, accompanied by symptomatic improvement and gain in body weight. There is no means of predicting the outcome in these cases, and oestrogen trial alone would be justified only when all other possibilities of treatment had been exhausted, on the understanding that the prospect of any substantial degree of improvement is remote, and that where it occurs it is almost certain to be impermanent and even fleeting. Although there is no evidence that one oestrogen differs essentially from another so far as this action in cancer is concerned, a suggested regimen would be to administer dienoestrol by mouth in doses of 0.3 mg. thrice daily, to increase the dose fairly rapidly to, say, 5.0 mg. three or four times daily, and to maintain treatment for a period of three months before withdrawing the drug completely; the course could then be repeated after an interval of several weeks.

It will be seen that much of the difficulty in reply to such a query arises from the circumstance that while we cannot affirm the application of oestrogens to the treatment of cancer other than that occurring in the prostate, neither can we completely exclude the possibility of benefit in individual cases of types arising elsewhere. Much patient work is required before the situation can be clarified, and those most closely concerned are the first to insist upon the need for present caution. As to other drugs or substances which have been sufficiently investigated, one cannot yet speak with confidence of any which hold out even this slight prospect of usefulness.

Multiple Warts

Q.—*A schoolboy, apparently in perfect health, has a mass of warts on his hands and knees, and they are now appearing on his lips and face. This is a distressing condition, and I shall be grateful for advice. Cauterizing the warts individually would be an impossible task.*

A.—Apart from the plantar variety, which are often extremely painful, warts require consideration only because of their slightly disfiguring and slightly contagious qualities. They may be cured by suggestion or clear up spontaneously, which explains the curative effect of many nostrums and perhaps some published methods of treatment. Individual warts can be destroyed by caustics or the cautery, if skilfully used, and provided other and more urgent matters allow of the time required. *X* rays and radium are the prerogative of the specially trained expert. As none of these methods, even when skilfully and properly used, is free from the risk of producing permanent changes in the skin, each of us will consider whether the patient's condition justifies the expenditure of time and skill on lesions which may at any moment vanish without trace.

Immunity after B.C.G. Vaccination

Q.—*How long does immunity to tuberculosis take to develop after vaccination with B.C.G., and how long does it last?*

A.—Calmette himself advised that infants given B.C.G. vaccine should be removed from contact with infection for 2 months thereafter, and re-vaccinated after 3, 7, and 15 years. There is evidence that some resistance to infection develops within about 2 months in the fact that the treated individual usually becomes tuberculin-sensitive within that time. In those particularly exposed to infection, such as household contacts and hospital nurses, natural infection may be expected to reinforce the immunity originally conferred by B.C.G.

Lice and the G.P.

Q.—*Could you advise me on the best method of protecting myself and my family from becoming infested with pediculosis corporis as a result of picking up odd specimens in certain parts of the practice?*

A.—Short of wearing protective clothing, or of the regular use of insecticides over the external clothing, the risk of picking up occasional lice cannot be avoided in some medical duties. But the risk of a sustained infestation (i.e., lice breeding in the clothing) from such rare specimens is extremely slight if the underclothing is laundered regularly. We know of colleagues who, in the course of research, have worked exclusively on pediculosis corporis, with several hours daily in a clinic of verminous persons, without finding more than one or two lice in their own clothing in the course of many months.

When the new insecticide D.D.T. becomes generally available it will be possible to make quite certain of protection by dusting the underwear weekly with an ounce of 10% D.D.T. powder.

Modern Methods of Blood Examination

Q.—*The various new procedures used this last five years or so in the recording of R.B.C.'s, M.C.V., etc., are rather confusing. Could we have an explanatory paragraph, mentioning the additional knowledge obtained over previous methods?*

A.—In the Wintrobe system for examining venous blood, which is now commonly used, a portion of the oxalated or heparinized blood is placed in a Wintrobe haematocrit tube, which is allowed to stand for one hour for the estimation of the sedimentation rate. The tube is then centrifuged at high speed and the percentage volume of cells read from the graduations on the tube. If the red cell count and haemoglobin are now determined in the ordinary way, the following indices can be calculated:

The mean corpuscular volume (M.C.V.) is determined by dividing the haematocrit percentage (× 10) by the number of red blood corpuscles in millions per c.mm., the result being expressed as cu. μ. For example, if the haematocrit percentage is 45 and the red blood corpuscles 5 millions per c.mm., the mean corpuscular volume is 90 cu. μ.

The mean corpuscular haemoglobin (M.C.H.) is determined by dividing the grammes of haemoglobin per 100 c.cm. of blood (× 10) by the number of red blood corpuscles in millions per c.mm., the result being expressed in micro-microgrammes, symbolized by the letters $\gamma\gamma$. For example, if the haemoglobin per 100 c.cm. is 15 grammes and the red blood corpuscles 5 millions per c.mm., the mean corpuscular haemoglobin is 30.0 $\gamma\gamma$.

The mean corpuscular haemoglobin concentration (M.C.H.C.) is determined by dividing the grammes of haemoglobin per 100 c.cm. (× 100) by the haematocrit percentage, the result being expressed in per cent. For example, if the haemoglobin per 100 c.cm. is 15 grammes and the haematocrit percentage 45, the mean corpuscular haemoglobin concentration is 33.3%.

Other constants, less frequently determined owing to the time-consuming nature of the techniques, are: (1) *the mean corpuscular diameter* and *coefficient of variation* of the red cells, which are measured by the Price-Jones technique; and (2) *the mean corpuscular fragility*, which is determined by measuring the percentage of haemolysis in graded strengths of hypotonic saline solutions.

The advantages of these measurements over the simple calculation of the colour index are numerous. There is a growing tendency to report haemoglobin values in terms of grammes of haemoglobin per 100 c.cm. of blood, instead of percentages of an arbitrary scale. The idea that 100% Haldane is the "normal" value has in fact led to very grave confusion, but once we abandon percentage scales of haemoglobin it is anomalous to try to preserve the colour index. Secondly, the haematocrit percentage is a valuable check on the haemoglobin level. Thirdly, it is possible for corpuscular volume and corpuscular haemoglobin to vary independently. In tropical anaemias, in particular, the cell volume may increase at the same time as the haemoglobin concentration falls, owing to a dual deficiency of P.A. factor and iron. This would not be revealed by the colour index. Fourthly, if we know the cell volume and the cell diameter we have an approximate idea of the shape of the cell and can calculate the cell thickness. In familial acholuric jaundice the cells are small and plump (spherocytosis), whereas in Mediterranean anaemia (Cooley) they are broad and thin (leptocytosis). In practice, then, the new procedures have proved of considerable value in the diagnosis and classification of anaemias.

INCOME TAX

Retirement from Colonial Service

G. A. is retiring from the Colonial Medical Service and becomes entitled to a gratuity and to a return of contributions to a pension fund plus 2½% interest. Are these sums liable to income tax?

⁂ In our opinion—no.

Dispensers' Salaries

W. H. is one of three partners in a practice. Each partner has a dispenser-secretary paid by himself, and the expense is treated as deductible from each partner's share of the firm's profits. The inspector of taxes insists that the three employees should be shown on one return to be made as for the practice as a whole.

⁂ Clause (2) of the Statutory Regulations governing P.A.Y.E. defines an "employer" as meaning "any person paying emoluments on his own account or on behalf of another person." Clearly each partner is the "employer" for the purpose of these Regulations, and we consider that they are entitled to make separate returns if they desire to do so.

LETTERS, NOTES, ETC.

Artificial Respiration

Dr. J. L. WHITWORTH (Melbourne) writes: The chief secretary of the Royal Life-Saving Society (March 17, p. 387) stresses the absence of proof of the arching of the diaphragm in the cessation of breathing, in defence of the Schäfer method of resuscitation against the rocking method outlined by Dr. F. C. Eve. But is this arching of the diaphragm really important? The response to treatment is surely more to the point; and Eve's method has proved its "response to treatment" reputation, especially at sea. As a matter of fact, the points of contention and their explanations and proof in the matter of cessation of breathing could be named and proved; but it is necessary to "kneel before one may rise" and admit the merits of Eve's method of resuscitation.

Treatment of Post-traumatic Headache

Mr. N. GARBER, F.R.C.S. (Johannesburg), writes: With reference to the question and answer on headache after fractured skull (April 14, p. 543), when all else has failed the following will be found of service: (1) oral administration of prostigmin hydrobromide 15 mg. three times daily for six to eight weeks, together with (2) intramuscular injection of 1 c.cm. of a solution of prostigmin methylsulphate 1 in 2,000 twice weekly for six to eight weeks, and (3) restricted fluid intake. Prostigmin potentiates the action of acetylcholine, which is a powerful vasodilator, and thus abolishes vasoconstriction of meningeal and labyrinthine arteries, which vasoconstriction is presumably the underlying cause of persistent post-traumatic headaches. For greater detail the original paper of Malone (*J. Amer. med. Ass.*, 1942, **119**, 861) should be consulted. This mode of therapy has yielded most encouraging results at the General Hospital, Johannesburg.

Women in Labour

Dr. CHARLES J. HILL AITKEN (Rotherham) writes: Is it not time the physiologists gave us in the *Journal* an account of the physiological mechanism behind labour, so that the expectant mother can be trained to cultivate the conditioned reflex essential for easy, and possibly painless, labour?

Hygiene in Sanatoria

Mr. H. P. HOLLOWAY (Hounslow, Middlesex) writes: One reads frequent references in the *Journal* and other medical papers (one in your last issue) to the hygiene which is taught in sanatoria to tuberculous patients. I have been a patient in several sanatoria in this country and have never heard a single word of such instruction given. The only advice I can remember was a printed notice hanging on a wall requesting patients not to clean their teeth in the ordinary wash-basins but to use the special basin provided. My own observations proved that even this advice was often ignored. It would surely not be asking too much to require all patients, before discharge, to attend one or more lectures on this very important subject.

Correction

Through an accident in the course of printing our annotation on "Folic Acid" (July 21, p. 91), vitamin B_c appeared as vitamin B in the 14th line.

THE RESULTS OF ROUTINE INVESTIGATION FOR Rh FACTOR AT THE N.W. LONDON DEPOT*

BY

G. PLAUT, M.D. M. LEITCH BARROW

AND

J. M. ABBOTT

Since Oct., 1942, this laboratory has undertaken to supply Rh-negative blood for transfusion purposes and to determine the Rh group of samples submitted for test. In the course of such routine investigations information has been accumulated on the incidence and clinical importance of the Rh factor. This is analysed below under the following headings: (I) The incidence of the Rh factor in Group O donors. (II) Results of examination of samples submitted from families giving a history suggestive of haemolytic disease of the newborn. (III) Routine serological investigation of unselected women attending an ante-natal clinic. (IV) Serological investigation of reactions following transfusion reported to the laboratory.

Methods

Test for Rh Factor in Red Cells.—Both cells and serum from samples submitted for test for Rh factor were first examined for their ABO group, using the tile technique (M.R.C. War Memorandum No. 9). The test for Rh factor was carried out in small test-tubes, 2 in. by 1/4 in., using one drop of anti-Rh serum of suitable ABO group or serum neutralized by saliva, and one drop of a weak cell suspension. The tubes were then covered with small glass caps and left in the incubator at 37° C. for two hours. After looking at the cell sediment one drop was carefully removed from the bottom of each tube and spread on a clean side. If no agglutination could be seen macroscopically, microscopical examination followed. Controls with two known Rh-positive bloods and one known Rh-negative blood were included in each test. From Oct., 1942, until Jan., 1944, the cell suspensions were put up against three different potent anti-Rh sera of appropriate ABO group. The cell suspensions were called Rh-positive if they were agglutinated by one or more of the test sera. After Jan., 1944, the cell suspensions were tested with one known potent anti-Rh serum only. Those which showed no agglutination with this serum were then tested with one known potent anti-Rh′ and anti-Rh″ serum.

Tests for Anti-Rh Agglutinins in Serum.—Tests for anti-Rh agglutinins were carried out by putting up the patient's serum in dilutions of from 1 : 1 to 1 : 512 against two suspensions of known Rh-positive Group O red cells (Rh_1Rh_2 and Rh_2Rh_2 (or Rh_2rh)), one suspension of known Rh-negative Group O red cells, and a suspension of the patient's own cells. In maternity cases the patient's serum was also tested against the baby's red blood cells if these were available and of compatible ABO group. Serum from cord blood was tested for anti-Rh agglutinins whenever possible. Tests for blocking antibodies (Wiener, 1944) or incomplete antibodies (Race, 1944; Race and Taylor, 1944) have been carried out only recently on sera of Rh-negative patients which contained either weak anti-Rh agglutinins or no anti-Rh aggultinins.

I. Incidence of Rh Factor in Group O Donors

In order to obtain a regular supply of Rh− blood for routine transfusion purposes and to build up a panel of known Rh− donors 5,837 unselected Group O donors have been tested. In the case of the first 2,944 donors tested only anti-Rh serum was used. In this series 2,472 (84%) were Rh+ and 472 (16%) were Rh−. The later 2,893 donors were tested with anti-Rh, anti-Rh′, and anti-Rh″ serum: 2,411 (83.3%) were Rh+, 432 (14.9%) were Rh−, 30 (1%) were Rh′, and 20 (0.7%) were Rh″. The sera from donors were not tested for anti-Rh agglutinins.

II. Examination of Samples submitted from Families giving a History suggestive of Haemolytic Disease of the Newborn or in whom Anti-Rh Agglutinins were found

Specimens of blood were received from 624 women with a history suggestive of haemolytic disease of the newborn or with a history of repeated stillbirths or miscarriages. In 133 instances the history suggested haemolytic disease of the newborn, as evidenced by the statement that the present or previous infants had anaemia, icterus gravis, hydrops foetalis, erythroblastosis foetalis, kernicterus, haemolytic disease, or early jaundice. In 3 women with a history of repeated miscarriages or stillbirths anti-Rh agglutinins were found; they are therefore included in the following analysis. The complete serological investigation of the remaining 488 specimens will form the subject of a further communication.

The term "Rh-negative" in the following paragraphs includes Rh′ and Rh″ subgroups, as the majority of the cases were investigated before the subgroups were recognized. The subgroups have been mentioned in the last column of Table I whenever they have been tested for.

An analysis of the table shows that 120 (88.2%) of the 136 women with either a history or serological findings suggesting haemolytic anaemia in an infant were Rh-negative and 16 (11.8%) Rh-positive. The Rh-negative mothers belonged to the following blood groups: Group O, 46 (38.3%); Group A, 60 (50.0%); Group B, 8 (6.7%); Group AB, 6 (5.0%). It proved possible to test only 85 husbands of the above 120 Rh-negative women; all but one were Rh-positive. The latter father could not be re-tested to determine if he belonged to one of the Rh subgroups. The 84 Rh-positive husbands belonged to the following blood groups: Group O, 50 (59.5%); Group A, 27 (32.1%); Group B, 4 (4.8%); Group AB, 1 (1.2%); unknown, 2 (2.4%). The red cells of only 55 affected babies with Rh-negative mothers were available for examination; 53 were Rh-positive, and 2 belonged to subgroup Rh′ (Table I, Cases 59 and 79).

---

* A report to the Medical Research Council.

Undefined	0	3	2	4	2 cases of anaemia 1 unknown	1 case of septicaemia 1 case of operation: *no* anti-Rh present	All women: *no* anti-Rh present

Anti-Rh agglutinins were found in the serum of 94 (79.6%) of the 120 Rh-negative women. In one of them (Table I, Case 61) the anti-Rh agglutinins may possibly have resulted from the transfusion of Rh-positive blood, as the woman's last baby was Rh-negative. After its birth she had received a transfusion of blood of unknown Rh group. Her first child died of haemolytic anaemia.

Anti-Rh agglutinins could not be found in 26 (21.7%) of the Rh-negative cases. In these the tests were carried out under varying circumstances: (*a*) after pregnancy with Rh-negative children (4); (*b*) only during pregnancy (4); (*c*) only during the first week after delivery (5); (*d*) during pregnancy and the first week after delivery (1); (*e*) only during the second week after delivery (2); (*f*) during the first and second weeks after delivery (1); (*g*) only during the third week after delivery (2); (*h*) 1 to 12 months after delivery (3); (*i*) over one year after delivery (2); (*j*) serum was not available (2).

Eight sera were tested for incomplete antibodies. Two had a higher titre of incomplete antibodies than of anti-Rh agglutinins; one had the same titre for both; five sera without anti-Rh agglutinins also had no incomplete antibodies. The cord serum of the affected babies was tested in 10 instances: no abnormal agglutinins were found in seven; anti-Rh agglutinins were present in two; one agglutinated the baby's own red cells.

The first pregnancy of the 120 Rh-negative mothers ended with a child normal at birth and during infancy in 80 instances. In 27 cases the child was suffering from haemolytic disease or was stillborn; in 5 the pregnancy ended in a miscarriage; and in 8 cases the child died from unknown causes or from causes other than with haemolytic disease of the newborn. Of the 80 normal first children 33 were Rh-positive, 5 Rh-negative, and 42 were not tested. There were eight Rh-negative normal children in families who had previously had children suffering from haemolytic disease of the newborn (Table I, Cases 9, 13, 20, 22, 23, 48, 53, 61).

The table includes 16 Rh-positive women. Eight of their husbands (5 Rh-positive, 3 Rh-negative) and eight of the affected children (5 Rh-positive, 3 Rh-negative) were tested. The serum of only one of the 16 Rh-positive mothers was put up against the baby's red cells; these were not agglutinated. The serum of one of these women could not be tested; in none of the other 15 were abnormal agglutinins detected.

III. Routine Serological Investigation of Unselected Women Attending an Ante-natal Clinic

Between Jan. 3 and June 5 and between Nov. 1 and Dec. 30, 1944, routine Rh tests were carried out on 433 women attending an ante-natal clinic. These women were unselected except that a large number had been sent to the ante-natal clinic at University College Hospital by outside doctors on account of a difficult obstetric history. This possibly explains the comparatively large number of 96 (22.2%) with histories of miscarriages and/or stillbirths.

339 women (78.3%) were Rh-positive, 79 (18.2%) Rh-negative, 11 (2.6%) Rh′, 2 (0.5%) Rh″, and 2 (0.5%) were Rh-negative tested with anti-Rh serum only. Out of 96 women who gave a history of miscarriages and/or stillbirths, 77 (80.2%) were Rh-positive and 19 (19.8%) were Rh-negative, Rh′, and Rh″ respectively. The Rh-negative, Rh′, and Rh″ women belonged to the following blood groups: Group O, 41 (43.6%); Group A, 44 (46.8%); Group B, 8 (8.5%); Group AB, 1 (1.1%). Of these women 60 had had no children and 34 were multigravidae.

The sera of the 94 women who were Rh-negative, Rh′, or Rh″ were tested for anti-Rh agglutinins. Of these women 53 (36 nulliparae, 17 multigravidae) were tested only during the first 6 months of pregnancy; 22 (13 nulliparae, 9 multigravidae) only between the 3rd and 9th months of pregnancy; 10 women who had had no previous pregnancies were tested some time during pregnancy, but further information was impossible to obtain. The 9 remaining women (1 nullipara, 8 multigravidae) were tested during and after pregnancy. Seven babies of this last group were tested; 6 were Rh-positive and 1 Rh-negative. One of the Rh-positive babies died of icterus gravis neonatorum; the other 6 were apparently normal. No information could be obtained about the remaining two. The mother of the baby who developed icterus gravis had been tested very early in pregnancy and no anti-Rh agglutinins were found then. Her serum contained anti-Rh agglutinins after delivery. Her husband and older child were both Rh-positive. Of the 94 who were Rh−, Rh′, or Rh″ this woman was the only one in whose serum anti-Rh agglutinins were detected. The sera of 20 of the Rh-negative women were tested for incomplete antibodies, but none could be found. No abnormal agglutinins were discovered in the serum of the seven babies tested.

Only 33 husbands of the 94 Rh-negative, Rh′, or Rh″ women were tested: 31 were Rh-positive; two were Rh-negative.

IV. Serological Investigation of Reactions following Transfusion

Reactions in 48 patients after transfusion of blood of compatible ABO group were reported to the depot director for further investigation: 28 reactions occurred in Rh-positive and 20 in Rh-negative patients. These reactions were not necessarily severe (see Table II). Of the 28 Rh-positive patients who had transfusion reactions six had received Rh-negative blood. No abnormal agglutinins were detected in their serum. A transfusion had been given previously to 10 of these Rh-positive patients. Of the 20 Rh-negative patients included in this series, two had had previous transfusions with known Rh-positive blood without any reactions. A second transfusion—in one case with Rh-positive blood and in the other with blood of unknown Rh factor—was followed by a reaction. Both patients had anti-Rh agglutinins in their serum.

Seven patients had previously been transfused with blood of unknown Rh group without reaction; 3 of them had a further transfusion with Rh-positive blood and with blood of unknown Rh group. The later transfusions were all followed by a reaction. Anti-Rh agglutinins were detected in the sera of two patients known to have had Rh-positive blood and in two who had had blood of unknown Rh group.

In 11 cases the first transfusion was followed by a reaction. One was a young child suffering from haemolytic anaemia and 10 were women, 5 of whom had only recently been delivered. Three of the maternity cases were those of women whose babies suffered from progressive anaemia or jaundice. One had anti-Rh agglutinins in her serum before transfusion, and these increased after the transfusion of Rh-positive blood (Case 23, Table I); the other two women were tested only after the transfusion with blood of unknown Rh group. One had anti-Rh agglutinins in her serum (Case 31, Table I); none could be detected in the serum of the third woman, who was not tested until 20 months after delivery (Case 44, Table I). The two remaining maternity cases were those of women who had been delivered of normal children; one received Rh″ blood, and no abnormal agglutinins could be detected in her serum; the second woman received blood of unknown Rh group after the delivery of a normal Rh-negative child. Her serum contained anti-Rh agglutinins. She had probably been previously sensitized during a pregnancy ending in the birth of a baby who died of haemolytic anaemia (Case 61, Table I).

The remaining 5 reactions occurring after the first transfusion were in patients not connected with maternity cases. One of these had Rh-positive blood and 4 had blood of unknown Rh group. Anti-Rh agglutinins could be detected in the serum of two of these women. No anti-Rh agglutinins were detected in the serum of the child suffering from haemolytic anaemia. Of these 20 Rh-negative patients 16 received one or more further transfusions with Rh-negative blood without any reaction. Five cases of this series are included in Table I (Nos. 1, 23, 31, 44, 61); anti-Rh agglutinins were found in the serum of each of these patients.

Discussion and Conclusions

The total number of Group O donors tested (5,837) was made up of two series: in the first, 84.0% were Rh-positive; in the second, 83.3% were Rh-positive. These figures are in close agreement with the other large series published in this country (Cappell, 1944).

The series of cases suggestive of haemolytic disease of the newborn has not been selected on as stringent a basis as some previously published series (Levine, 1941; Levine *et al.*, 1941; Potter *et al.*, 1943; Race *et al.*, 1943; Boorman *et al.*, 1944; Cappell, 1944), since it proved difficult to obtain by correspondence complete reports stating the clinical and pathological findings. The wide area served made personal contact impossible. Nevertheless, 88.2% of the total of 136 cases proved to be Rh-negative, and 79.6% of these had anti-Rh agglutinins in their serum.

The 433 ante-natal cases tested showed 78.3% to be Rh-positive—i.e., a lower proportion than occurred in the unselected donors and in other series published from ante-natal clinics (Cappell, 1944; Murray, 1944). There is at present no explanation of this low figure. The relatively high incidence, however, of Rh-negative mothers suggests the importance of routine Rh-testing in ante-natal clinics.

The number of transfusion reactions investigated was not large. The findings, nevertheless, suggest that the transfusion of Rh-negative individuals with Rh-positive blood is a not uncommon cause of relatively mild reactions and may result in more severe reactions. Of the 48 cases examined 20 (41.7%) proved to be Rh-negative, and 11 of these patients had anti-Rh agglutinins in their serum. Nine of the 20 Rh-negative patients had had previous transfusions without reactions, five with Rh-positive blood. It may be of interest that the remaining 11 patients who had a reaction after the first transfusion were all women. Diamond (1942) and Vogel *et al.* (1943) have published 10 cases each of reactions in Rh-negative patients following the transfusion of Rh-positive blood.

We are grateful to Prof. F. J. Browne for his collaboration in sending samples from his ante-natal clinics at University College Hospital.

Continuing its campaign for children's nurseries as a permanent feature of our national life, the London Women's Parliament (24, High Holborn, W.C.1) has issued a circular for distribution to mothers telling them how they can help to achieve this end. In an accompanying letter this organization welcomes the Government's recent decision to introduce a national nursery certificate for trained workers, but points out that some other assurance is needed that the nurseries are to remain—such as the continuance of the 100% grant to local authorities, the reopening of the "wartime" training schemes (closed last January), and the opening of the nurseries themselves to all who need them.

ACUTE INVERSION OF THE UTERUS

BY

J. V. O'SULLIVAN, M.D., M.A.O., F.R.C.O.G., F.R.C.S.

Obstetric Surgeon, City of London Maternity, Queen Mary's, and Bearsted Memorial Hospitals; Obstetric and Gynaecological Surgeon, Kingston County Hospital

The object of this paper is to draw attention to a simple method of replacement of the acutely inverted uterus which my colleagues and I have not heard of to date—to wit, intravaginal hydraulic pressure attained in a very simple manner. This succeeded in the following two cases.

Case I

Mrs. A., aged 31; first pregnancy, 1938—normal labour and puerperium; infant 6 lb. 8 oz. The second pregnancy was normal; the expected date was given as early February. On Feb. 15, 1945, surgical induction by Drew Smythe catheter was performed. Spontaneous delivery of a living child weighing 6 lb. 12 oz. occurred 12 hours later. The first and second stages of labour together lasted three hours. There was moderate haemorrhage, so Credé's expression was practised, and immediately the uterus became completely inverted, the separated placenta being delivered at the same time. The uterus was replaced in the vagina at once, but further manipulation was considered inadvisable in view of the patient's shocked condition. I saw her 1 hour and 10 minutes after the inversion. She was pale and sweating; B.P. 80/50 and pulse 140. On palpating the abdomen no fundus uteri could be felt, and on parting the labia the red fundus uteri could be seen with the placental site on the fundus. Treatment for shock included three pints of blood. Three hours later the patient's general condition had greatly improved, so open ether was given and replacement by taxis was attempted. This manœuvre caused a rapid deterioration in her condition, so I decided to give a douche preparatory to a later attempt. In carrying out the douche the tip of the nozzle, guarded by my fingers, was passed towards the posterior fornix; my forearm happened to block the vaginal orifice and the vagina ballooned out, and to my surprise and pleasure the uterus promptly returned to its correct position, the signs of shock rapidly disappeared, and the patient made an uninterrupted recovery.

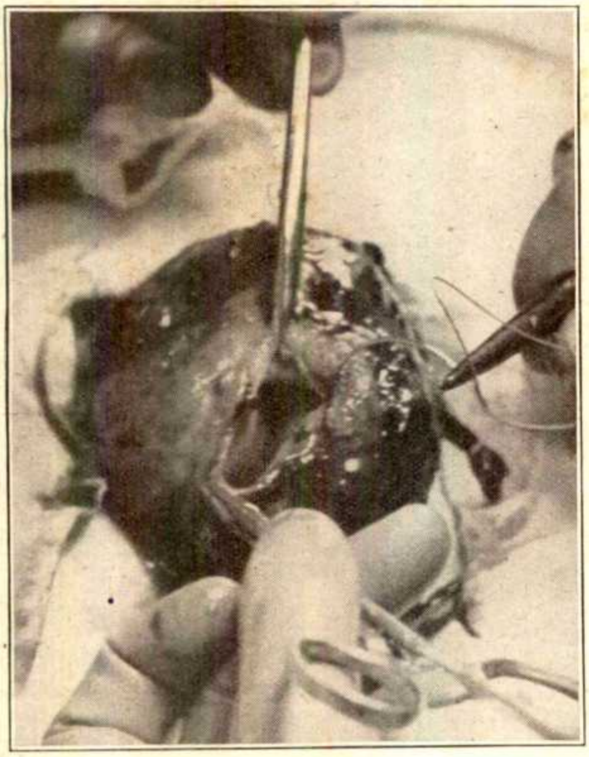

FIG. 1.—Case II. Inverted uterus, showing complete rupture.

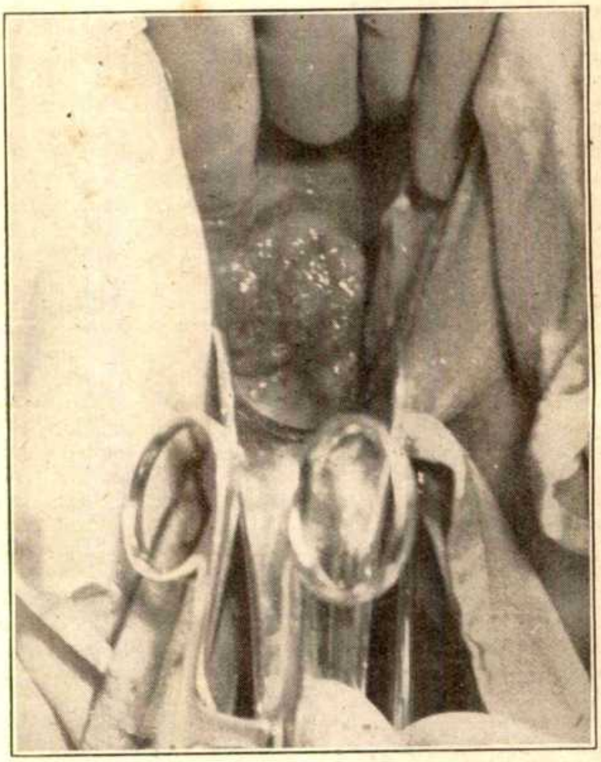

FIG. 2.—Case II. Cervix after replacement of inverted uterus by ballooning vagina, etc., by sterile douche.

Case II

Mrs. B., aged 24; an especially interesting case, as she had had acute inversion with her second confinement. In 1941 the first pregnancy and labour were normal apart from mild toxaemia towards the end of pregnancy. In 1942, with her second, she had a normal ante-natal history. On Oct. 4, 1942, after a surgical induction on the same day, she had an easy spontaneous delivery of a female child weighing 7 lb. 3 oz. There was an adherent placenta, and after blood-grouping she was given a general anaesthetic, when the placenta was found to be adherent to an inverted uterus. The placenta was peeled off. The patient at the end of this operation was so shocked that no attempt could be made at replacement of the uterus. She was given a blood transfusion and gradually improved. The next day her haemoglobin was only 52%. She was given sulphonamides prophylactically. On Nov. 8 an Aveling's repositor was introduced and the uterus slowly and successfully replaced.

In her third pregnancy Mrs. B. attended at 36 weeks with the breech presenting; external version failed to correct the presentation. The pregnancy remained normal and the patient went into spontaneous labour on April 23, 1945, and had an easy breech delivery of a female child weighing 7 lb. 2 oz., alive and well. When the placenta was thought to have separated from the uterus an attempt was made to express it by fundal pressure and traction on the cord. Inversion of the uterus followed at once. As the patient was bleeding, an attempt to strip off the placenta was made, and this resulted in two large tears—one near the fundus, 2 in. long, through all three layers; the second on the left side, 1¼ in. long, also complete. At this stage the patient was desperately ill, with B.P. 70/40 and pulse 160. The placenta was finally stripped—bleeding being controlled by ergometrine and hot packs—the uterus dusted with sulphanilamide powder, and replaced in the vagina. Blood drip, 2 pints, was given, then reconstituted human serum, 2 pints. I saw this patient about 9 hours after the inversion, when she complained of backache and severe pain in her left shoulder. Her condition had improved sufficiently to warrant further treatment, though no major surgery could yet be attempted, her B.P. being 110/75 and pulse 120. Light open ether anaesthesia was given. The uterus was gently delivered through the vagina. The adjacent peritoneal cavity tubes and ovaries were inspected through the tears and found normal. The two large tears were sewn up in two layers—continuous catgut for the peritoneum and interrupted catgut for the muscle layer, which was found to be thin over the lateral tear.

The uterus was douched with proflavine and dettol, then dusted with sulphanilamide powder and again replaced in the vagina. Gentle taxis failed to replace the uterus and increased the pulse from 120 to 150; the B.P. also began to fall. At this stage, in spite of the ruptured uterus, which had been firmly sutured, it was decided to make an attempt to replace with hydraulic pressure as in the previous case. The vagina was distended to capacity by means of a dettol-and-proflavine douche, retained by blocking the vaginal outlet with my forearm, aided by my assistant's (Dr. England's) hands. The uterus went back promptly and smoothly, the douche-can being held two to three feet above the vagina. The accompanying photographs, taken at the time, show (Fig. 1) the inverted uterus, with one of the complete tears; (Fig. 2) the cervix after replacement.

At the end of the operation there was no clinical evidence of any free fluid in the peritoneal cavity and the patient's condition was fair. Her puerperium was febrile for two weeks, but ultimately she made a complete recovery under first sulphanilamide then penicillin treatment.

Synopsis of the Complication

Acute inversion of the uterus means a rapid turning of the uterus inside out *per vias naturales*. This serious complication usually occurs during the third stage, though sometimes it may begin towards the end of the second stage by the pull on a short cord, or soon after the separation of the placenta. Various authors put the incidence at between 1 in 200,000 and 1 in 17,000 deliveries. It usually occurs after a full-term labour, but has been reported in a five-months miscarriage.

The condition may be divided into (*a*) incomplete—including all degrees from a placental dimple to inversion into the vagina; (*b*) complete—where the fundus is outside the vagina. The common cause is mismanagement of the third stage of labour by: (1) pulling on the cord when the uterus is relaxed; (2) pushing on the fundus of a relaxed uterus; (3) a combination of these two. In the two cases just described one or both were caused by one of these three ways. The catastrophe is most likely to occur if the placenta is attached to the fundus. Careful records of this point would be of great help. Well-authenticated cases of spontaneous inversion have been reported.

The symptoms are usually very severe shock, out of all proportion to the amount of blood lost; a tendency to bearing down after the placenta has been delivered; and, later in the puerperium, a persistent red haemorrhage or oft-repeated small haemorrhages, with obvious signs of anaemia and difficulty in micturition.

The signs are as follows. A complete inversion is self-evident. An incomplete inversion may be mistaken for a large fibroid polyp, but if the bladder is empty an abdominal examination will reveal the absence of the fundus uteri in the abdomen, and in its place a saucer-shaped depression where the fundus has been invaginated into the uterine cavity. Examination reveals a large rounded polypoid mass with a broad pedicle in the vagina. This, with the abdominal findings, renders the diagnosis obvious.

The prognosis is always very grave, the mortality varying between 23 and 80% in different series. If left alone, sloughing and/or sepsis may occur. In some cases spontaneous reinversion in a matter of hours, in others even during the passage of years, has been reported.

Treatment.—(1) Immediate replacement as soon as the inversion occurs, and before shock develops, without attempting to strip the placenta if it is still attached. (2) If the patient is very shocked, first clean the uterus and change the complete inversion into an incomplete by gently replacing the inverted uterus in the vagina, then raise the foot of the bed, put a sterile pad on the vulva, and carry out treatment for shock. (3) When shock is controlled replace the uterus as described above by hydraulic pressure.

My grateful thanks are due to Dr. H. R. England and Dr. H. Mayer for their great help in the second case, and to Dr. L. B. Bourne for the excellent photographs.

Writing on vision and selection of personnel in industry in the July/August number of *Industrial Welfare and Personnel Management* Mr. Joseph Minton, F.R.C.S., expresses concern at the haphazard methods of vision testing in industry, many firms insisting on visual standards which are too high, others having no standards at all. As he says, men and women with all grades of vision can be employed in industry to-day, and he gives a chart for use as a general guide when selecting workers. In the same issue is an account by Col. S. D. Large of the planned exercises, mental and physical, at an Army convalescent depot which enables 85% of the men to leave fit. From his experience 70,000 cases Col. Large concludes that the principles practised at this depot could be applied with gain in civil centres. Dr. J. B. L. Tombleson describes a scheme operating in Bedford which provides a medical service to 10 firms employing about 7,000 workers.

ADMINISTRATION OF PENICILLIN BY INTRAMUSCULAR INFUSION

BY

E. C. TURTON,* M.B., B.S.

(The Radcliffe Penicillin Unit of the Medical Research Council)

This account deals solely with the clinical aspects of the administration of penicillin by intramuscular infusion as described by Morgan, Christie, and Roxburgh (1944). Experience with 30 patients is summarized and attention is principally focused on three points: (i) whether this method was preferred by the patient to intermittent intramuscular injection; (ii) whether it was convenient for the medical officer; (iii) whether there was any ill effect from its use.

Technique

The instrument used was the Eudrip 2 (see Fig.), briefly referred to by McAdam, Duguid, and Challinor (1944). It is similar in principle to Eudrip 3, which they describe in detail, but instead of the 4-oz. "medical flat" bottle for reservoir there was a 100-c.cm. burette with 24 graduations. In the top of the burette there is a rubber bung with two holes for the glass tubes. To the tube which passes to the bottom of the burette is attached the capillary air intake, to the other a piece of rubber tubing and a clip for release during filling. This is done by filling the side arm and elevating it. The side arm and other connexions are similar to those of Eudrip 3.

Eudrip apparatus No. 2 in use.

Three types of needle were used: the ordinary needle in an M.R.C. pattern blood-transfusion set; one similar to this but with two side perforations; a needle of the Middlesex pattern.

---

*In receipt of a grant from the Medical Research Council.

Cetavlon was used for skin-cleansing. The needles were inserted without local analgesia.

The penicillin used for the first three or four cases was made by Pfizer, the remainder by Eli Lilly. A drip was not set up on a patient unless it seemed likely that it would be required for at least three days and unless he had had a course of injections previously. All the patients were in a 30-bed ward reserved for men from B.L.A. who had been specially selected as having severe compound fractures—of the leg in most cases. The majority of the drips were started within a week of wounding while the condition of the men was still acute. The usual site of the drip was the antero-lateral aspect of the thigh or the pectoral region, but on occasion both the calf and the trapezius muscle were used satisfactorily.

A drip was set up in 7 to 15 minutes by a medical officer, who checked its speed after an interval of approximately 1 to 3 hours. After that the nursing staff was responsible for its watching and refilling, the medical officer checking it only once or sometimes twice a day. The needles were changed either when there was an indication or every third or fourth day, although at first they were changed more frequently. The later tendency was to leave the needles *in situ* for longer periods—at the most 7 days.

The intermittent injections were administered by the nursing staff. No nurse was allowed to give the injections until she had been instructed by the medical officer and had been seen by him to do this satisfactorily. A subcutaneous needle of the size of a "Record" fitting No. 18 was used. Care was taken to see that the needles were sharp. 16,600 units of penicillin in 2 c.cm. of saline were given three-hourly—always slowly. For 24 hours one thigh was used for the injections, then a buttock for the next 24 hours, and similarly on the other side.

Patients' Preference

Out of 30 patients, 24 were quite emphatic that they preferred Eudrip 2 to injections. The commonest cause of drip preference was that sleep was undisturbed. Only two preferred the drip because of the actual pain experienced from the injections; but many had a considerable dislike of the needle-pricks, while two stated that their "nerves went to pieces" with the injections. Incidentally, these two were severely ill patients who required rest, and both took drips excellently.

In 4 cases in which both pectoral and thigh regions were used the thigh was strongly preferred, but patients disliked frequent changes of site, owing to the sensation on introduction of the needle. Drips were therefore started, where possible, while the patient was still under the influence of general anaesthesia following operation. Hence the indications from the patients' point of view for drip therapy were: (i) inability to sleep while having injections; (ii) fear of injections, which is easily transmissible round the ward; and (iii) pain from injections.

Six patients preferred injections, the chief reason being that these were quickly over and almost painless, while with a drip the needle was always present, which if not actually painful could be felt. That movement was hampered was also a source of complaint. Two had a strong dislike of the drip. Neither of these could give any obvious reason, and one, who was intelligent and bore severe pain without complaint, had such a horror of the drip that it had to be discontinued after a day.

Convenience of Use

The main difficulty in using the drip was the maintenance of a slow and steady supply of penicillin. The common cause of an irregular flow was a leak at the air capillary owing to the rubber splitting or a bung which did not fit perfectly. These resulted in too great a flow to the leg, with pain, to relieve which the delivery tube was sometimes clipped off, with subsequent blockage of the needle. The latter became a serious danger after half an hour's cessation of flow, although it occasionally happened sooner. Out of a total of 11 blocked needles, 8 had some antecedent technical difficulty with the drip. In four cases the blockage was probably avoidable and due to inexperience. A striking feature was that if there were no technical difficulties a drip would run to time almost exactly, with the minimum of interference. The number of drips going at a time varied, but it was found possible for one medical officer to have seven running simultaneously without interfering with his other duties.

A typical history of such a drip is as follows:

Day 1, 14.00 hrs.: Drip set up. Needle, left thigh. 100,000 units penicillin in 100 c.cm. saline
Day 2, 14.30 hrs.: Refilled. 100,000 units penicillin in 100 c.cm. saline
Day 3, 13.45 hrs.: Refilled. 100,000 units penicillin in 100 c.cm. saline
Day 4, 13.30 hrs.: Refilled. 100,000 units penicillin in 100 c.cm. saline
Day 5, 14.30 hrs.: Discontinued. End of course. No redness or swelling at needle site. Minimal tenderness on firm pressure on site

The following is an account of a not so satisfactory drip, such as was encountered occasionally.

Day 1, 22.00 hrs.: Drip set up. Middlesex needle, right thigh. 100,000 units penicillin in 100 c.cm. saline
Day 2, 09.00 hrs.: Drip too fast all night and had required frequent readjustment. Small leak round bung. Needle blocked. Stylet passed and needle reinserted near by
" 16.30 hrs.: New set put up, as old one still leaked round bung
Day 3, 18.30 hrs.: Refilled; new set running regularly (100 c.cm.)
Day 4, 09.30 hrs.: Slight tenderness at drip site
" 19.30 hrs.: Refilled (100 c.cm.)
Day 5, 20.30 hrs.: Discontinued. Very slight tenderness at drip site

Ill Effects

Fifteen patients admitted to some tenderness on firm palpation over the needle site after withdrawal, but pain was not a feature of the drips in any instance. In three cases very slight skin redness and in one case a moderate area of reddening were noticed. In eight cases there was a trace of localized oedema, which would probably not have been observed unless specially looked for. Subsequent stiffness of a limb with delayed return to full function was not found in any case, nor was there any abscess formation or pus in the needle track. The effectiveness of the treatment was demonstrated by measurement of blood penicillin levels, by the disappearance of Gram-positive pyogens from wounds, and the steady progress made by patients towards recovery—local and general.

The general impression at the end of the series was that, in a hospital where there are a practised operator and several nurses well acquainted with the technique of continuous intramuscular infusion, it is the method of choice for the patient and no more laborious for the staff than intermittent injection. In some cases in which injections are tolerated badly, it is of great value. When it can be alternated with a course of injections it is especially acceptable to those who have to submit to a lengthy course of penicillin therapy. Some time, however, must elapse before a staff becomes proficient in using the apparatus, and, for this, instruction and practice are necessary.

Summary

Out of 30 patients 24 preferred Eudrip 2 to intermittent intramuscular injections.

Local reactions were slight or *nil*. No abscesses occurred.

With an experienced staff the time taken for supervising the accurate running of the apparatus is not considered greater than that required for repeated intramuscular injections.

The brands of penicillin used for both methods of administration were the same.

A further 10 drips have been set up in the same ward with less experienced staff, and they bear out the conclusions drawn in this paper—that it is a practicable form of treatment in a busy ward provided the staff has some instruction and practice.

I wish to thank Lady Florey and Prof. Christie for their great help in the preparation of this paper; and also Drs. McAdam, Duguid, and Challinor for permission to reproduce their illustration of Eudrip 2.

It is announced from Leeds that Yorkshire has—apart from the Army Blood Transfusion Service itself—contributed more blood and blood products to the armed Forces than all the other regional services put together. Between January, 1941, and May of this year 25,028 bottles of whole blood and 128,523 bottles of dried serum or plasma were supplied. The number of donors presenting themselves is now falling off, and a warning was issued by the Public Relations Officer that general, maternity, and military hospitals have still to be supplied, and that consignments of plasma are being shipped to the Far East.

USE OF BENZEDRINE SULPHATE BY PSYCHOPATHS

THE PROBLEM OF ADDICTION

BY

H. J. SHORVON, M.B., B.S., D.A., D.P.M.

Psychiatrist, E.M.S.; Chief Assistant, Psychological Medicine Dept., St. Thomas's Hospital

Benzedrine (amphetamine) sulphate was first introduced in America in 1935 by Prinzmetal and Bloomberg for the treatment of narcolepsy. Guttmann in 1936 reported its use in this country in cases of depression, and in collaboration with Sargant described its psychological effects in 1937. Since then an enormous literature has accumulated on its pharmacological and physiological action and its therapeutic application in narcolepsy, post-encephalitic Parkinsonism, alcoholism, epilepsy, obesity, etc. Its use in psychopathic states and behaviour disorders, both in adults and in children, has been described by Cutts and Jasper (1939), Bradley and Bowen (1941), and Korey (1944), and, on a larger scale in connexion with electro-encephalographic studies, by Denis Hill (personal communication). The beneficial effects of benzedrine in certain types of psychopathy have been observed in numerous instances by my colleagues at the Sutton Emergency Hospital. Hill, as quoted by Sargant and Slater (1944), has noted that certain psychopaths can tolerate benzedrine in enormous doses and benefit from the therapy, as opposed to normal persons, who are intolerant of high doses. The case here recorded illustrates this point.

Case Report

A man aged 35 was admitted to Sutton Emergency Hospital on Jan. 26, 1945, complaining of depression, insomnia, and bad nerves. There is a family history of psychopathy. The patient has been a nail-biter all his life, had periodical attacks of stammering, had nightmares, was enuretic up to the age of 12, and at school was a poor mixer. After normal schooling he trained for commercial art at Cardiff Technical College and had a succession of jobs in Wales and later in London. He had been married 17 years and had two children, but his wife left him in 1940 after they had had some "differences."

He is described as a persistently unhappy reserved man with few friends, stubborn, anxious, highly strung, sensitive, and easily depressed. Since 1939 he was a fire fighter in the N.F.S. and went through the London "blitzes," but had to "steel himself" to do so. He expected every bomb would be his last, but did not report sick. In March, 1944, during a raid, he received a slight injury to his arm and leg, and the "sudden realization that he had been hit at last produced shock." He fainted repeatedly, and remembers little after that until he found himself in hospital, where he remained some weeks. Sulphonamides with which he was treated made him depressed. After returning to duty he experienced some nasty flying-bomb incidents, and was tense and sleepless. His condition deteriorated, and he was sent to a Fire Force in North Wales for a month, but felt worse on return, yet continued on duty. His relatives were all evacuated and he had to look after himself. Finally he reported sick and was sent into Sutton Emergency Hospital. On admission he was tense and depressed, stammered, and stated that he had lost interest and had some thoughts of suicide, but was anxious to get well. He had bad dreams and felt that people were talking about him. There was a slight loss in weight. He insisted that he did not want to leave the N.F.S., because it gave him some measure of financial security.

Physical examination showed him to be a thin, asthenic individual. There were small scars on his right leg and the ulnar border of his right forearm. His pupils were dilated and B.P. was 120/95. There was no physical abnormality.

At the time of admission he gave no indication that he had been taking benzedrine. After five days of moderate sedation he was restless and agitated, and was put on continuous narcosis with sodium amytal and paraldehyde. The restlessness and agitation persisted for some days and he complained of vivid dreams of his experiences. His appetite was ravenous. When taken off narcosis he was treated with daily intravenous 33% glucose and with large doses of nicotinic acid, thiamine, and riboflavin. There was rapid physical and mental improvement, and he was no longer confused and agitated, was able to carry on a reasonable conversation, and slept well on small doses of paraldehyde.

He admitted he had been taking large doses of benzedrine early on during the narcosis, and later stated that he first began to do so during the 1940 raids. At that time he took it when he needed it, and was scared of its potency; but soon he took daily six tablets of 5 mg. each. He found no ill effects—it seemed to banish all tiredness and fatigue, and gave him a strong feeling of well-being—and by increasing the dose he experienced "unlimited energy." Soon he was taking nine to ten tablets, and in the latter part of the 1940 raids 30 tablets daily. This larger dose produced a tendency to some "subtle" depression a few hours afterwards: "nothing very suicidal, but at the same time a distinct sense of depression, irritability, and an increase of perspiration." The effect of well-being was increased by strong tea: "benzedrine with a strong cup of tea was better than a good meal." His average dose was nine tablets three times a day; this produced no sense of intoxication, but merely increased his energy and allowed him to do a better job. "It stimulated my sense of perception, imagination, and formulation of ideas." After many months he cut down his benzedrine consumption to eight tablets a day when the air raids ceased, but increased the dose whenever he was called upon to do extra work or go without sleep. His injury in 1944 suddenly deprived him of benzedrine for a month when in hospital, and, he states, "I can't say that I missed it a great deal, and although I could not sleep well I felt no craving for it"; but he resumed taking 25 to 30 tablets daily during the flying-bomb era. When on maximum doses he had to take 30 gr. of barbitone to help him sleep, but found that the uplift of benzedrine was carried over until the next morning. A fortnight after admission to Sutton Emergency Hospital he said he had no craving for benzedrine: "It rather interests me, as I expected to feel a craving for it when I came into hospital, but I did not." He rapidly improved, put on 8 lb. in weight, and lost his tenseness, but throughout maintained that although he did not want any benzedrine, he "felt it had been a good thing for me."

Discussion

The *Journal of the American Medical Association*, in an editorial in 1938, issued a warning on the dangers of the use of benzedrine for obesity, for which it was commonly being employed in America. That journal stated: "Its use over long periods is certainly not without danger, particularly to the circulatory system." Lesses and Myerson (1938) replied to this: "As to addiction, the drugs to which human beings become addicted are the narcotics. There is no evidence in the entire literature of medicine that stimulants become habit-forming. One of us (Myerson) has had clinical experience with benzedrine sulphate for more than two years in a very large number of cases and has not seen a single case of addiction in the sense that a person, otherwise well, now feels it necessary to take the drug habitually and in ascending doses to produce the desired effect." Waud (1938) stated that a definite tolerance for amphetamine is slowly built up, and that increasing doses are necessary to produce the original effects, but he indicated that the question of addiction was not settled at the time. Despite the many hundred papers published in connexion with benzedrine very few describe possible cases of addiction. Friedenberg (1940) quotes a case in which a patient in a period of six months took five 10-mg. tablets twice daily for obesity; reduction of the doses was followed by fatigue and depression and a demand for larger doses. Hahne (1940) described a case in which the patient had been taking benzedrine sulphate for nearly two years, averaging twelve 10-mg. tablets daily, and on many occasions double this amount. He was an alcohol addict before starting benzedrine, and, experimentally, was prescribed two benzedrine tablets daily. He returned many months later, and Hahne states: "He came looking fine. He had gained weight, and claimed that the taking of the drug had completely banished his craving for alcohol. He said, however, that if he missed taking the benzedrine he would get a terrific craving. He claimed that he could not carry out the daily routine without it. Withdrawal caused nervousness, exhaustive fatigue, an inability to think straight, and sleeplessness. In spite of the fact that he had been a lifelong drunkard he had not touched a drop since he began taking the tablets. Aged 49, his B.P. was 115/90." The last fact is interesting because one of the points raised against the regular use of benzedrine is said to be its hypertensive effect (Morse, 1936; Beyer, 1939). It will be noted that the blood pressure of my patient was normal. Cases of so-called addiction have therefore only rarely been recorded. Guttmann and Sargant (1942) stated that they had not met with cases of addiction to benzedrine—the only queries were a few instances in patients with abnormal tolerance. They say: "The fact that patients cling to a drug from which they derive physiological benefit cannot be regarded as liability to addiction. The same could be said of insulin or cough mixtures." In my patient there was little sign of "craving" when suddenly deprived of benzedrine in hospital in March, 1944. He says he did not miss it, and for five days in hospital before I put him on to continuous narcosis he took no benzedrine and showed no change in symptoms apart from some restlessness and sleeplessness. He was able to carry on in the N.F.S. for some years with large doses of benzedrine, and would almost certainly have broken down without it. Like a diabetic, he was efficient with his drug and inefficient without it. There were no serious physical changes as a result of its long use. Some cases of idiosyncrasy and collapse after the use of even small doses of benzedrine have been described in the literature, but they are rare. Bloomberg (1940), on the other hand, recorded his studies of three patients with narcolepsy who had been taking at least 70 mg. of amphetamine every day—for two years and eight months in two cases and for one year and eight months in another. In spite of the massive doses over a long period no significant abnormality was found in exhaustive regular tests: there was no rise in the basal metabolic rate, no rise in blood pressure, no evidence of organic damage to organs or blood, etc., and no evidence of addiction or habit-formation was found. We must conclude, therefore, that there is no evidence of physiological damage from benzedrine even in prolonged and massive dosage.

Summary

A case is reported of a patient taking large doses of benzedrine (amphetamine) sulphate for over four years, the daily consumption being from twenty-five to thirty 5-mg. tablets for many months periodically.

The only apparent withdrawal symptoms were increased restlessness and sleeplessness. There were no apparent physical ill effects. The blood count was normal. After stopping the benzedrine the patient had a marked hunger, which confirms the fact that benzedrine reduces the appetite.

Although the use of benzedrine was abruptly stopped when the patient entered hospital, he made no request for it.

Sleeplessness induced by benzedrine was well compensated by barbitone.

This paper discusses the question of "benzedrine addiction" and notes the clinical experience that certain types of psychopath can well tolerate and benefit by large doses of benzedrine.

I wish to thank Dr. L. Minski, medical superintendent of Sutton Emergency Hospital, for permission to publish this case, and to Drs. Slater, Sargant, and Hill for their help and advice.

A circular from the Ministry of Health states that a substantial extension of mass radiography will not be practicable until normal production of the highly specialized apparatus required becomes possible and reduced demands on medical man-power release the skilled staff essential to the proper use of the apparatus. In view, however, of the general desire for an extension of mass radiography as soon as conditions permit, the Minister reminds tuberculosis authorities (other than the few who already have mass radiography units in operation) that the M.R.C. Committee on Tuberculosis in Wartime in its report issued in September, 1942, advised that a high standard of quality of miniature radiography is necessary for correct interpretation and that the use of compromise apparatus is to be condemned. Experience has since confirmed the soundness of this advice. The Minister suggests, therefore, that, when the present difficulties begin to relax, authorities wishing to undertake mass radiography should first seek the advice of his expert consultants, who will give every help and guidance.

ERYTHEMA NODOSUM AND TUBERCULOSIS

BY

WILLIAM D. GRAY, M.B., Ch.B.

Temporary Assistant Tuberculosis Officer, Durham County Council

Recent articles in the medical press have stressed the common association between erythema nodosum and tuberculosis. The rheumatic theory of its origin, however, is still too prevalent among general practitioners, and often blinds them to the necessity for referring these cases to the tuberculosis officer for investigation. Perry (1944) states that in 72% of cases among school-children erythema nodosum marks the onset of primary tuberculosis. Daniels (1944) records 5 cases out of 284 tuberculin-negative nurses who became tuberculin-positive after an attack of erythema nodosum. The Norwegian authority Ustvedt claims that the condition is practically always a tuberculous one. The following cases have been seen at a tuberculosis dispensary in the past 18 months.

Case 1.—Boy, 13 years; referred to dispensary with erythema nodosum in June, 1943. Fading nodules on both shins, but nothing heard in chest. Failed to return to dispensary for two months. Cough then present, with pain in the chest. Temperature 99.6° F. Pleural effusion found at left base. No heart murmur. Patient admitted to sanatorium, and Mantoux test found positive to 1 in 10,000 dilution. Effusion cleared normally, and chest film a year later showed calcified hilar glands. Attack of acute nephritis while in sanatorium. Now well, and working. Family history: mother's uncle had tuberculosis and brother has tuberculous cervical glands.

Case 2.—Boy, 12 years. Developed erythema nodosum in Aug., 1944, and was treated in bed by the family doctor. When allowed up, started a cold and complained of periodic attacks of pain in the right side of chest. On Oct. 12 examination revealed right pleural effusion. Tuberculin patch test gave a slightly positive human reaction and a strongly positive bovine one. Treated in bed for a further eight weeks. A chest film on Dec. 9 showed absorption of fluid and a large right root shadow, suggesting a primary complex. He now feels well and is gaining weight. Family history: nothing of tuberculosis. Mother had a cough, but chest film was negative.

Case 3.—Youth, 16 years. Developed some pain in the right side in June, 1944, followed by erythema nodosum on the left leg. Referred to dispensary; a chest film showed opacity in and above the right horizontal fissure. Developed a slight cough, and admitted to sanatorium on Jan. 2, 1945. Film then showed a large root shadow with some infiltration in the right lower zone. There were two calcified shadows in the left root. No family history of tuberculosis.

Case 4.—Girl, 10 years. Referred with a history of erythema nodosum two months before, in June, 1943, and as a contact of her elder sister with active pulmonary tuberculosis and a positive sputum. A chest film showed some shadowing in the right midzone. Has been kept under observation for the past 18 months; complained of pleurisy pain in June, 1944. A chest film in August suggests that bronchiectasis may be developing at the right base. Her weight and appetite are good.

Case 5.—Girl, 16 years; referred with pain in the left shoulder-blade, cough, and sputum. Was just recovering from an attack of erythema nodosum. A chest film showed a fan-shaped shadow contiguous with the left root shadow. A few crepitations were heard in the left subclavicular region. Sputum was negative for T.B. Admitted to a sanatorium for treatment. Her father has a chronic cough, but refuses to be examined.

Case 6.—Girl, 6 years; referred with erythema nodosum and history of frequent colds and "styes" on eyelids. Bluish nodules on both shins. Tuberculin patch test gave a slightly positive human reaction and a strongly positive bovine one. Left tonsillar gland slightly enlarged. A chest film showed large left root shadow; suggesting a primary complex. Two or three weeks later she developed phlyctenular conjunctivitis and corneal ulcers, followed by a recurrence of erythema nodosum. As her general condition was poor, sanatorium treatment was advised. Family history: aunt attends dispensary with old mainly calcified disease and a negative sputum. Mother's chest film negative. Father has had chest trouble for years, but refuses examination.

Case 7.—Boy, 9 years; referred on account of a cervical abscess. Swollen glands first appeared after an attack of erythema nodosum in Jan., 1944, which had been described as surface rheumatism by the family doctor. The glands subsided after rest in bed, but recurred in October with abscess formation. The abscess was opened by the doctor and discharged intermittently. He was admitted to a sanatorium for treatment, and the Mantoux test was found positive in 1 in 25,000 dilution. A chest film was normal. There was no definite family history; but the child frequently visited a house where somebody had a bad cough and swollen glands in the neck.

Case 8.—Boy, 6 years; referred because a lodger in the house had been found suffering from pulmonary tuberculosis with a positive sputum. The left tonsillar gland was enlarged, and a tuberculin patch test was found positive for human and bovine tests. A chest film showed a primary complex on the left side. He had had an attack of erythema nodosum in Jan., 1944, diagnosed as rheumatism.

Case 9.—Boy, 7 years; referred with erythema nodosum, corneal ulcers, and phlyctenular conjunctivitis. Tuberculin patch test positive for both human and bovine tests. A chest film showed an enlarged right hilar gland, suggesting a primary complex. Rhonchi were heard in the right lung, and there has been loss of weight. He visits a house where one of the family died of tuberculosis.

Summary and Conclusions

Nine cases of erythema nodosum are described. Seven were of school age; two were young adults. Six are males, three are females. Three are contacts of known cases of pulmonary tuberculosis, and another has a family history of tuberculosis. Two have been visitors to a tuberculous household, and two more have relatives suffering from chronic cough who refuse to be examined. Only two gave no history of suspicious contact. All the children gave a positive tuberculin reaction. The tuberculous lesions met with were pleural effusion, pulmonary tuberculosis, phlyctenular conjunctivitis with corneal ulcers, tuberculous cervical glands, enlarged or calcified hilar glands, and a simple primary complex. No history of rheumatism was given by any of the patients.

Erythema nodosum is often associated with tuberculous lesions, and is a manifestation of tuberculous infection. All cases should be referred to the tuberculosis officer for investigation and follow-up. Every case of erythema nodosum should be regarded as a newly infected case of tuberculosis, and therefore search should be made among family and friends for the unknown source of infection. While the cases may develop nothing serious, the occurrence of ill-health and minor tuberculous lesions is frequent enough to warrant attendance at a tuberculosis dispensary in every case.

My thanks are due to Dr. D. F. Macrae, chief clinical tuberculosis officer to Durham County Council, for permission to publish these records, and to Dr. J. W. Gray, medical superintendent, Holywood Hall Sanatorium, for allowing me to see Case 3, a patient in the sanatorium.

Medical Memoranda

A Freakish Occurrence

A patient suffering from pulmonary tuberculosis with an apical cavity was found to need the division of certain adhesions which were preventing the establishment of a satisfactory pneumothorax. Through the thoracoscope (a single-instrument pattern) multiple adhesions suitable for division were displayed. They were cut with the electrocautery in the usual way until one only remained. This was a rather fleshy posterior adhesion which it was judged would require novocain infiltration of its parietal attachment over a rib. For the uninitiated it may be explained that such injections are made through a long metal tube to the end of which a small needle, about ⅞ in. long, of the Schimmelbusch type is screwed, the whole being introduced to the site of injection through the thoracoscope. While this injection was being made a sudden movement of the instrument caused the little needle to snap off. It was subsequently found that the needles of this batch were unduly brittle owing to a slight defect in the tempering. A search of all parts of the pleural cavity visible in the field of the telescope was made, but the small portion of needle, about ¾ in. long and the thickness of a hypodermic needle, could not be seen. It was believed that it had fallen into the posterior sulcus and, as the patient was in a semi-upright position, probably lay just above the diaphragm. It seemed unlikely that a small portion of sterile needle in this position would cause any trouble and, in any case, radiographic location was essential before further steps, if any, were taken. The patient was therefore returned to the ward.

The instrument was now taken to pieces, cleaned, and re-sterilized by boiling. The next case also had multiple adhesions, which were divided. Before withdrawing the instrument a final look round revealed a thin straight reddish object lying on the upper surface of the lower pulmonary lobe. It was about the size and shape of the missing part of needle, but as this line of thought seemed too fantastic to be seriously pursued the suggestion was made that the object was possibly a blood-cast expelled from an artificial pneumothorax needle used at one of the previous refills. Satisfied with this explanation I withdrew the instrument.

The *x*-ray photographs taken on the following day, however, showed beyond doubt that the small piece of needle broken off in Case 1 was now in the chest of Case 2, and that it was the blood-stained portion of needle which had been viewed through the thoracoscope. How the transference occurred is not known with certainty, but it was found just possible to insert a portion of a small needle between the telescope and the outer sheath where a slight groove is produced by the electrical lead to the lamp.

The needle after breaking off must have passed directly backwards into the instrument and there become attached by a little blood clot, the fixation being aided probably by the heating effect of a cautery both upon the blood and the film of lubricant (K-Y jelly) employed. In this position it withstood the ordinary method of cleaning followed by boiling for several minutes, but was pushed out by the insertion of the telescope when the sheath of the thoracoscope was already in the thorax of the second case.

The chances of such a series of events occurring must be very small; my non-mathematical friends all speak in terms of millions.

NORMAN C. LAKE, M.S., F.R.C.S.

Congenital Discoid Internal Cartilage

Congenital abnormalities of the external cartilage in the form of either a complete or a partial disk are relatively common, and are most often encountered in adolescence, when they first cause trouble. We have been unable to find any reference to a similar condition affecting the internal cartilage, and so great an authority as Prof. McMurray remarks that he has never encountered a complete disk on the inner side. A fairly careful perusal of the literature makes us feel that the following case merits recording.

Photograph of the specimen. The black glass rod is in the tear on the superior surface of the cartilage.

This patient, a soldier aged 29, passed A1 for the Army 4½ years ago, and was admitted to Alder Hey Emergency Hospital on Oct. 20, 1944. His knee-joint had never troubled him until five weeks before admission. He was walking out of the Naafi when his left knee gave way with a loud crack, causing him to stumble. This happened several times on the way back to his billet, and finally the knee-joint became fixed in a semi-flexed position. His M.O. applied a back splint, which was kept in place for four weeks, and after its removal he was allowed up, but still found walking very painful and difficult.

On admission to Alder Hey there was a definite effusion in the knee-joint, and extension was limited by a few degrees. A bucket-handle tear of the internal cartilage was diagnosed. At the operation it was found that the upper articular surface of the tibia was completely covered by a somewhat irregular fibro-cartilaginous disk. With some difficulty this disk was completely removed. Post-operative examination of the specimen revealed that it was a complete disk with a split extending from the back end to the front of the cartilage, and in addition on its deep surface a horizontal split was discovered.

Progress was uneventful, and on discharge 10 weeks later he had a full painless range of movement with no effusion, and had reached the "heavy" class in physical training.

This case is published with the kind permission of the medical superintendent, Dr. W. E. Crosbie.

Reviews

A NEW TEXT OF GALEN

Galen on Medical Experience. First edition of the Arabic Version with English Translation and Notes. By R. Walzer. Published for the Trustees of the late Sir Henry Wellcome. (Pp. 164. 12s. 6d.) London: Oxford University Press.

The discovery of a new text of Galen is something of a literary event, and the source in this case particularly interesting, if not wholly unexpected. The works of Galen were well known to the Nestorian writers of the ninth century, who translated them into Syriac. In the next century they were turned from Syriac into Arabic. In Greek they were largely neglected. Thus certain of them were lost in the language in which they were written, but of these some have survived in Arabic versions. The best known of these Arabic survivals is the great treatise on dissection, *De anatomicis administrandis,* the last part of which is known only in that language. When this was published some forty years ago hopes rose high of further discoveries of like kind. The present work is thus a fulfilment of those hopes. The manuscript on which it is based was discovered in the library at St. Sophia in Constantinople in 1931, and the work is now available to English readers.

Galen was a complex character. He was at once an able experimenter, a courtly physician, and a contentious disputator. This work shows him in the last role. It was written in A.D. 150 before he was 21, and was intended to reproduce a disputation held in Smyrna between Galen's master, the dogmatist Pelops, and the empiricist Philippos. We know very little of the empiricist school, and this work extends our knowledge considerably. It is peculiarly valuable for this purpose, since Galen expressly refrains from putting his own views into the mouth of the empiricist. There are very few texts of Galen available in English. This new one, clearly set forth and admirably printed, provides a side of Galen that has not hitherto been presented in our language. We are grateful to Dr. Walzer for this literary service.

THE ADVANCE OF MEDICINE

The March of Medicine. The New York Academy of Medicine Lectures to the Laity, 1944. (Pp. 121. 11s. 6d.) New York: Columbia University Press; London: Oxford University Press. 1945.

The New York Academy of Medicine continues its laudable custom of annually inviting the lay public to its comfortable and acoustically perfect theatre to hear lectures on the advance of medicine. It is noteworthy that for the first time the format of the book containing these accords with the war economy standards of this country instead of its previous more elaborate style. Particularly striking is Prof. C. M. Macleod's lecture on chemotherapy, the best non-technical account of the subject we have read. He reminds us that even in 1881 von Behring believed that the killing of bacteria within the body was for ever impossible without also killing the host. He also has the gift of metaphor; discussing the role of para-aminobenzoic acid in bacteriostasis, he compares the sulphonamides to the flies used by fishermen, which the trout mistakes for something (i.e., para-aminobenzoic acid in this case) he has been accustomed to devour with relish, and so is hooked. Moreover, some drug-fast bacteria seem to have acquired the property of excluding the sulphonamides from the cell—like the wise old trout who detects the baited hook. But the whole lecture repays careful reading. Dr. Glen King gives a lucid and straightforward account of food in relation to civilization, and adds a useful warning. Remembering how wholly ignorant we were thirty years ago concerning vitamins, it is absurd to conclude that our knowledge of such things is now complete, and in view of past mistakes "every new development in the art of processing, storing, or preparing food must be scrutinized in the light of the accumulated knowledge of nutrition." It was a gracious thought to invite our Minister at Washington, Sir Gerald Campbell, to lecture on the effects of science on human beings. He considers that "the two main departments in which we have of late allowed ourselves to benefit from the gifts of science are personal comfort and war," with disastrous results. "The scientist cannot wholly isolate himself from the rest of human affairs and remain indifferent to the wider implications of his discoveries . . . if civilization is to advance into that spacious era which science is laying open to us." Lieut.-Col. T. T. Mackie gives a vivid historical account of the influence of epidemics on the outcome of wars and indeed on the fate of nations. The Crimean War, with its gross medical defects, nevertheless led to a new era in medicine itself. It is evident that the medical problems of armies and navies at war, and the need for maintaining their establishments in peace, have indirectly contributed to the progress of medicine and to the control of epidemic disease: "The great general of the future must have a great physician on his staff."

DIGESTIBILITY OF DIFFERENT FOODSTUFFS

Les Régimes des Hépatiques. By Étienne Chabrol. (Pp. 61. No price given.) Paris: Librairie J.-B. Baillière et Fils. 1941.

Les Régimes des Gastropathes. By Paul Carnot. (Pp. 128. No price given.) Paris: Librairie J.-B. Baillière et Fils. 1943.

Arctic explorers and shipwrecked mariners dream continuall of food, and similar circumstances probably explain the appearance of these two monographs printed in France during th occupation. They are typically French in their accounts o the digestibility and characteristics of different foodstuffs. Th same might not unfairly be said of their reliance on traditio and theoretical deduction rather than controlled experimen and observation. It is difficult, for example, to get a clea picture of what is meant by "the liver in hyperactivity (hypertrophic cirrhosis and sundry nutritive and dyspeptic conditions)." Biochemical observations on patients with larg livers indicate that the functional activity of the liver is reduced In fact, much of these books will appeal more to the layma than to the physician, as, for example, the suggestion tha dyspepsia is commonly produced by excess of protein, carbohydrate, or fat in the diet and is to be corrected by a carefu balance of these ingredients. These prescriptions will be mor useful for the treatment of wealthy hypochondriacs than fo the handling of patients in ordinary general or hospital practice. Ascites and oedema are treated by giving 1,500 c.cm. milk every day for three or four weeks. Vitamins C and and 50 grammes of liver a day are added, but no other foo or drink. There seems no rational basis for reducing protei and calories in this way when the patient is already in a sta of hypoproteinaemia, and we should need successful recor of controlled trials before recommending such a regime.

PSYCHOLOGY IN GENERAL PRACTICE

Psychology in General Practice. Edited by Alan Moncrieff, M.D., F.R.C.P. The Practitioner Handbooks. (Pp. 199. 12s. 6d.) Published on behalf of the *Practitioner* by Eyre and Spottiswoode. 1945.

This collection of essays will be extremely useful to the fami doctor, and the non-psychiatric specialist will find that a stud of them will help him to understand the "overtones" of h specialty, which are constantly present when he deals wi the human being who is his patient. On the whole the vario authors give the reader essentials which he ought to kno without burdening him with technicalities or the elabora devices of special treatment.

The first four chapters deal with generalities of approac classification, diagnosis, and treatment; the next four wi the more specific mental illnesses; then comes a most valuab chapter by Dr. Rogerson on visceral neuroses, which should carefully studied by all doctors. Dr. Halliday's chapter psychosomatic medicine and the rheumatism problem is stim lating, but leaves the impression that this is a subject whi needs much more exact and carefully controlled study by t conjoined work of the rheumatologist and psychiatrist. Wi one statement, however, we can cordially agree—that "fibr sitis" is a label far too loosely and frequently applied. D Maberly's and Dr. MacCalman's chapters on problems childhood deserve careful study, for it is here that the chan of preventing mental illness and maladjustment lies, not on for children themselves but for the parents as well. D MacCalman's chapter on minor degrees of mental defect very valuable.

The work of Service psychiatrists among their personnel h shown how important is backwardness in preventing pro adjustment and how useful the backward can be if their tas are fitted to their capacity, and the same lessons have to learnt in relation to civil life. Dr. Curran warns his readers against a too ready acceptance of the cliché that all crime is disease, and points out the use and the limitations of psychotherapy in the treatment of delinquency. Mrs. Edkins's chapter on psychiatric social work shows how useful an auxiliary the well-trained psychiatric social worker can be. Dr. Griffith pleads for greater knowledge of sex problems by the family doctor, who ought to be the adviser of his patients on these matters, but who often fails lamentably. This is too big a subject to be dealt with in a small space, but indications are given of where fuller information may be obtained. Finally Dr. Tattersall gives a detailed summary of how to get a patient into and out of a mental hospital, which should be of great service to the practitioner.

This little book deserves a wide public, and whoever acquires it will not find that much professional time passes before he has found a use for it.

Notes on Books

An interesting book, *Annals of the University of Otago Medical School, 1875–1939*, by Professor D. W. CARMALT JONES, has reached us from A. H. and A. W. Reed, 182, Wakefield Street, Wellington, New Zealand. The inception of this school in the South Island was in 1870, when the New Zealand University Act, by which degrees in medicine could be granted, became law. Tedious birth pains set in, and it was only in 1875 that the Faculty of Medicine was opened. The first doctor to practise in Otago Province was Dr. Joseph Crocone, who arrived in 1836. Gradually other wandering doctors arrived, but it was not till 1861 that Alfred Eccles, F.R.C.S., of St. Bartholomew's Hospital, went out from Britain and made himself the moving spirit in a series of undertakings which contained the germ of the Otago Medical School. At that time there was a big increase in immigration, following the discovery of gold in Otago, which attracted 200,000 diggers to Dunedin. The book opens with an account of the nature and history of the New Zealand country, its zoological and botanical peculiarities. Succeeding chapters are devoted to the establishment, development, and present status of the Medical School. The settlement was made on a considered plan, which placed Otago far ahead of all other New Zealand cities in the matter of higher education. Great pains were taken in the choice of professors, and men of " quite exceptional quality " were secured. Otago was the first British University to grant degrees to women. Biographical notices are given of the medical leaders associated with the fortunes of the College. Prof. Carmalt-Jones in compiling his history has given us a model for the establishment of Colonial colleges on a sound basis. He takes his readers through all the stages of development of a fully constituted university.

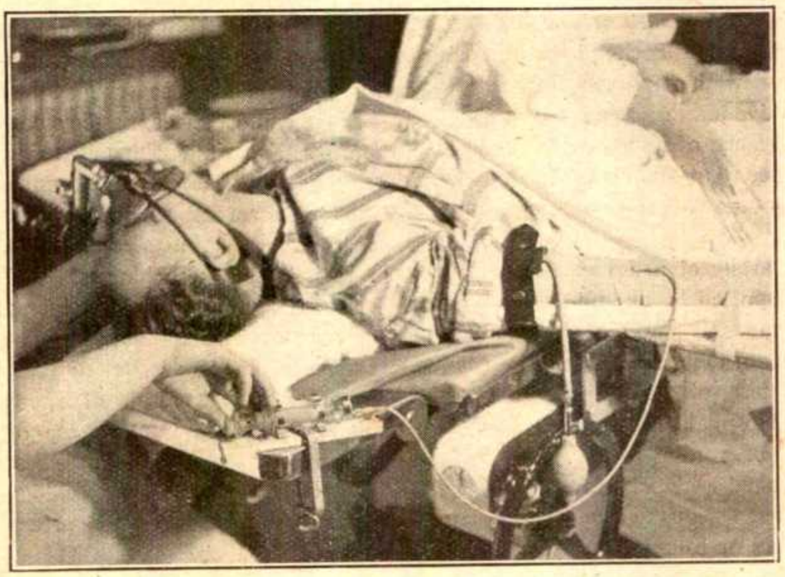
Mechanical Dentistry, by EDWARD SAMSON (The Technical Press, Ltd., Gloucester Road, Kingston Hill, Surrey; 15s.) is an excellent textbook for dental mechanics, and describes in detail the basic principles of their craft. So much advance, however, has been made recently in the use of plastics in dentistry that a new chapter must be added to bring the volume up to date.

Preparations and Appliances

A SIMPLE APPARATUS FOR CONTINUOUS PENTOTHAL

Dr. H. MARCUS BIRD, D.A., honorary anaesthetist, West Suffolk General Hospital, writes:

During the past few years a large number of devices for administering continuous pentothal have been described. The great majority of them share the faults of being cumbersome and difficult to sterilize except in a fully equipped theatre.



The ingenious bicycle-valve apparatus described by Cochrane in the *Journal* of Aug. 26, 1944, has neither of these disadvantages, but, in its original form, detaches the anaesthetist from the patient's head. This can be overcome by increasing the length of the rubber tube to about 2 feet, when the syringe can be clamped to the head of the table and controlled with one hand, leaving the other hand free for the patient or the anaesthetic trolley, as can be seen in the photograph. This set-up is not ideal, for the longer tube not only spoils the excellent vein-seeking properties of the apparatus, but in addition any accidental compression of the tube or constriction of the arm causes back-flow of blood into the needle with blockage from clot. This can be prevented by using two bicycle valves, one close to the needle and the other attached to the syringe, but this arrangement offers so much resistance to injection of the solution that it is difficult to give the very small amounts required during the more prolonged administrations.

The most satisfactory combination is a glass needle mount attached to a female syringe fitting by a 2-foot length of rubber tubing with an ordinary bicycle valve interposed 2 inches from the glass viewer. This gives a considerable amount of backlash in the syringe, but by compressing the plunger sharply by 1/2 c.cm. and releasing it immediately about 1/10 c.cm. of solution will pass the valve and needle, quite sufficient to keep the needle clear.

The internal bore of the rubber tubing is very critical. It must fit the valve snugly enough to prevent backflow, but not so tightly as to necessitate the use of any force in the syringe, or the adapter may be blown off it. (A bayonet catch here might be an advantage.) If different strengths of solution are used, it is wise to use them always in different patterns of syringe to avoid any possible confusion—for example, an all-glass syringe containing 5% solution for induction and a Record containing 2½% for maintenance. The syringe can be clamped to any convenient object in a carrier constructed from two spring tool-clips screwed to a strip of wood. A third, very small, clip holds the mount while the syringe is changed or refilled.

In use it is advisable to inject a few drops of solution at least once every ten minutes (though the needle will often remain clear for very much longer than this), and for this reason the 2½% solution is preferable for maintenance, especially as surprisingly small amounts of pentothal are required when supplementary nitrous-oxide–oxygen or cyclopropane is employed.

The capacity of the apparatus is about 4 c.cm., and this must be allowed for if changing from one strength of solution to another, as the first 4 c.cm. injected will be of the strength formerly in use.

Sterilization is simplicity itself, as the whole apparatus can be either boiled or carried in a spirit-proof container ready for immediate use. This, together with its portability and ease of construction from local sources, should commend its use under active service conditions.

CHANGES IN THE KNEE-JOINT AT VARIOUS AGES

Osteo-arthritis is a disease which is found in all vertebrates and is known to have occurred in man since the earliest times. The Neanderthal man of La Chapelle (40,000 B.C.) had hypertrophic spondylitis of the fifth to seventh cervical and first to third thoracic vertebrae,[1] and Timbrell Fisher[2] has found that prehistoric animals in the British Museum show evidence of advanced degenerative joint disease. The aetiology of osteo-arthritis has, however, always remained a matter for dispute. Many modern writers think chronic vascular disease resulting in local anaemia is the important causative factor, while others suggest that dysfunction of one or more of the endocrine glands is responsible. While a few authors incriminate a specific metabolic disorder, a larger group regard extra-articular infections with streptococci or other organisms as a major aetiological factor; some of these look upon degenerative joint disease and rheumatoid arthritis as variant manifestations of the same arthropathy; yet others consider the absorption of toxins from malfunctioning intestines as a cause. Axhausen and Pels[3] put forward the thesis that arthritis deformans is caused by a septic necrosis of cartilage or bone, and saw a close relation between this disease and the various epiphysial necroses, including osteochondritis dissecans; and some writers[4] even view the hyperplastic changes so characteristic of degenerative joint disease as a regenerative phenomenon. The importance of an inherited predisposition to the disease has been stressed, but most observers have regarded it as a process closely connected with the ageing of articular tissues.

In view of this great variety of aetiological hypotheses, many of which are unsupported by anatomical or laboratory evidence, Walter Bauer, when the Commonwealth Fund placed him in charge of the Robert W. Lovett Memorial Foundation for the study of crippling diseases at the Massachusetts General Hospital, resolved to study the anatomy and physiology of normal joints. Now he and his colleagues have published a classic monograph on the changes in the knee-joint at various ages.[5] They obtained knee-joints from necropsies or following amputation from 63 individuals ranging in age from one month to 90 years, who, so far as was known, had no history or clinical evidence of articular disease. All the joints were removed unopened, while care was taken to secure the nutrient arteries; they were all *x*-rayed before further examination. They were then opened and studied both macroscopically and microscopically. The results of these investigations are beautifully recorded with no fewer than 28 plates in their monograph. It was found that all the joints obtained from individuals beyond the age of 15 exhibited changes like those observed in hypertrophic arthritis. The findings indicated that joints remained unimpaired for a very short time after complete development. The material, therefore, not only allowed the authors to achieve their original purpose of establishing the normal conditions of the knee-joint at each age decade but enabled them to describe in detail the development of degenerative joint disease.

This condition first becomes manifest in the superficial layer of the articular cartilage in the second and third decennia. This tissue—smooth, glistening, translucent, resilient, and bluish-white in normal growing subjects—acquires a yellowish opaque colour and firmer texture indicating a progressive loss of elasticity, while at the same time the surface layers exhibit small blisters, linear grooves, and pits in those areas where weight-bearing is concentrated. Microscopically there are slight irregularities in the surface from which fibrillated shreds of tissue have been detached; here the cells of the uppermost stratum are more numerous and form a dense layer with their long axes parallel to the joint lumen. The subjacent matrix has comparatively fewer cells, and the intercellular substance is swollen. Individual cells are voluminous and heaped in small clusters. Alterations in the calcified zone of cartilage may be an early or late accompaniment of changes taking place in the overlying hyaline layers. Early swelling, altered staining reaction, and, finally, loss of cartilaginous matrix accompanied by cellular necrosis and the absence of any evidence of inflammation show the process to be one of primary degeneration. Though the first changes appear in articular cartilage, parallel developments appear in other parts of the joint. Those occurring at the articular margin are perhaps the most evident; they consist first of proliferating fibrous tissue, but with advancing years metaplastic fibrocartilage, hyaline cartilage, and bone develop. The cartilage-bone border, subchondral trabeculae, and cancellous spaces of the joints studied showed manifold but no constant pathological changes. In individuals over 40 the calcified layer of cartilage increased in thickness due to calcium deposits in the hyaline zone, and when these were extensive the end-plate of the subchondral bone was irregular as the result of spotty ossification stimulated by and advancing into areas of abnormal calcification. Changes in the synovial membrane occurred late, usually after the sixth decade; villous structures hanging as threads from the synovial surfaces were the most obvious abnormality.

Bauer and his colleagues point out that there are two fundamental causes which are probably the predisposing factors in every example of degenerative joint disease. One is the paucity of the cellular constituents of articular cartilage, its remoteness from blood supply, low respiratory rate, and extremely limited faculty for autogenous repair. The other is the effect of mechanical stress and strain resulting from joint function upon a tissue whose specific means of resistance to such use has been depleted. The most constantly observed concomitant to the so-called primary degenerative joint disease is increasing age.

ANTI-VIVISECTION SOCIETIES AND INCOME TAX

For the past fifty years anti-vivisection societies have been granted exemption from income tax on interest on their very large investments, as the result of a finding in the case *In re* Foveaux (1895, 2 Chancery, 501) by Mr. Justice Chitty on the ground that "the intention is to benefit the community; whether, if they achieved their object, the community would, in fact, be benefited is a question on which, I think, the Court is not required to express an opinion." *In re* Grove-Grady, Plowden *v.* Lawrence (1929, 1 Chancery, 557) a very large bequest, to be administered solely by anti-vivisectionists for the benefit of animals, was successfully disputed on the ground that it would not benefit the public. In his judgment on that case Mr. Justice Russell (now Lord Russell of Killowen) threw doubt on the above decision when he said: "For instance, anti-vivisection societies, which were found to be charities by Mr. Justice Chitty, and were described by him as near the border-line, might possibly, in the light of later knowledge in regard to the benefits accruing to mankind from vivisection, be held not to be charities."

On the outbreak of war in September, 1939, Dr. G. P. Crowden, who had taken up the Grove-Grady Will case, proceeded on active service, and Sir Leonard Rogers took over his work as hon. secretary of the Research Defence Society in addition to his duties as hon. treasurer. In 1942 Sir Leonard drew up a memorandum on "Are Anti-vivisection Societies Good Charities?" This was much on the lines of his paper in the *St. Bartholomew's Hospital Journal* in 1941 entitled "The Case Against the Anti-vivisectionists: Their Anti-Public Health and Anti-War Efforts and their Cruelty to Animals." The committee of the Research Defence Society directed this memorandum to be sent to the Treasury, with the request that the grounds on which anti-vivisection societies were exempted from income tax as "charities" should be reconsidered in the light of the immense advances in curative and preventive medicine due to animal experiments during the last half-century. After a question on the subject had been put down in the House of Commons by Prof. A. V. Hill, Secretary to the Royal Society, the Inland Revenue authorities asked for evidence in support of the statements in the memorandum, and on receipt of this from nine medical and veterinary scientists a test case was heard in December, 1943, by the Special Commissioners of Income Tax. The commissioners spent three days in taking the evidence of the director and treasurer of the National Anti-Vivisection Society on one side, and of the following scientists on the other side: Major-Gen. L. T. Poole, Director of Pathology at the War Office; Sir Edward Mellanby, F.R.S., Secretary to the Medical Research Council; Dr. R. D. Lawrence; Dr. J. W. Trevan, Director of the Wellcome Physiological Research Laboratories; Sir John Ledingham, F.R.S.; Sir William Savage, President Society of Medical Officers of Health; Dr. J. H. Burn, F.R.S., Professor of Pharmacology in the University of Oxford; Prof. G. H. Wooldridge, Past-President of the Royal College of Veterinary Surgeons; and Sir Leonard Rogers, F.R.S., whose book *The Truth about Vivisection* was put in as evidence regarding the great advances in human and veterinary medicine subsequent to the verdict for the scientists in the final report of the Royal Commission published in 1912.

The findings of the Special Commissioners of Income Tax became public only when they were read in the course of an appeal in the King's Bench Division of the High Court before Mr. Justice Macnaghten, who gave his decision on July 27 of this year.[1] Owing to the General Election results having just appeared, the case received very scanty notice in the Press. The following are the essential points in the two findings. The Special Commissioners found (contrary to the contentions of the National Anti-Vivisection Society) that: "We are satisfied that the main object of the Society is the total abolition of vivisection, including in that term all experiments on living animals whether calculated to inflict pain or not, and (for that purpose) the repeal of the Cruelty to Animals Act, 1876, and the substitution of a new enactment prohibiting vivisection altogether." They also found that the evidence of "a number of very distinguished men called as witnesses for the Crown" proved conclusively that "(*a*) a large amount of present-day medical and scientific knowledge is due to experiments on living animals; (*b*) many valuable cures for and preventives of disease have been discovered and perfected by means of experiments on living animals, and much suffering both to human beings and to animals has been either prevented or alleviated thereby. We are satisfied that if experiments on living animals were to be forbidden (i.e., if vivisection were abolished) a very serious obstacle would be placed in the way of obtaining further medical and scientific knowledge calculated to be of benefit to the public. We were very impressed by the evidence of Major-Gen. Poole, Director of Pathology at the War Office, as to the great value of experiments on living animals in connexion with the successful carrying on of the present war by the maintenance of the health of the troops and the avoidance or minimizing of many diseases to which soldiers in the field are particularly liable."

The Special Commissioners concluded that if it was their function to weigh the assumed benefit from the Society's efforts in the "advancement of morals and education among men" (no express evidence in support of which has been given) such benefit "was far outweighed by the detriment to medical science and research and consequently to the public health which would result if the Society succeeded in achieving its object, and that, on balance, the object of the Society, so far from being for the public benefit, was gravely injurious thereto, with the result that the Society could not be regarded as a charity. . . . But, upon the authorities, we regard ourselves as precluded from so holding." The Special Commissioners therefore felt bound to allow the Society's claim. Mr. Justice Macnaghten, after hearing legal arguments for two days, reversed that decision by the following judgment: "In view of these authorities [quoted in the earlier part of his judgment] it was for the Society to prove affirmatively that it was a society established for charitable purposes only." Not only did the Society fail to prove that fact, but the evidence called for the opposition to the Society's claim proved that the main object of the Society was the total abolition of vivisection, and that the attainment of that object, so far from being beneficial, would be gravely injurious to the community. In these circumstances it was the duty of the Special Commissioners to reject the Society's claim for exemption from income tax. "In my opinion, therefore, this appeal must be allowed, and the order granting the exemption must be revoked." Costs were allowed against the Society.

NEUROLOGICAL TRAINING OF THE FUTURE

Clinical neurology has for a century been one of the cynosures of British medicine. But time marches on, and hospital and medical services and undergraduate education are now the subject of close scrutiny. It is not surprising, therefore, that neurology, like psychiatry and paediatrics, should come up for review. Recent trends in general medicine and orthopaedics, as well as in neurosurgery and psychiatry, have tended to invade a domain long regarded as a neurological Tom Tiddler's ground. The recent report of the Royal College of Physicians Committee on Neurology is therefore of topical interest. The committee was elected to consider (1) the training of specialists in neurology, (2) the conditions of recognition as a consultant or specialist in neurology, and (3) the relation of neurology to general medicine and to psychiatry, with special reference to hospital and consultant services. The committee's report may not be wholly approved by all physicians, or even by all neurologists. Nevertheless it would be difficult to better it. It is arguable that neurology—like other specialties—should be left to develop in its own way and in its own time, without the help or hindrance of outside influences. So neurology has evolved in the past, and no one can decry its accomplishments. But circumstances are now proving too much for natural growth and development, and the radical changes which are likely to occur in medical education and in national hospital and health services cannot be ignored even by the most complacent or conservative.

The function of the neurologist in one way differs from that of the practitioners of some other aspects of medicine—e.g., psychiatry, tuberculosis—for the neurologist is a consultant rather than a specialist; he is a judge who sums up and advises as to the nature, origins, outcome of an illness, and the disposal of a sick person, and he is not the purveyor of a particular line of treatment. Hence neurologists have been comparatively few in number, self-selected, highly trained and experienced. If schedules of training should become necessary—and such may of course be deplored—then they must be exacting, eclectic, and extensive. Such epithets may be applied by some in criticism of the suggested programme of the neurological committee, which includes as minima: 18 months' whole-time study of general medicine after registration; the M.R.C.P.Lond. or its accepted equivalent; six months in the whole-time study of pathology, physiology, and anatomy of the nervous system, together with normal psychology; a year's devotion to psychiatry (including six months' hospital residence); and 18 months' study of clinical neurology (including a year's hospital residence). This means that the neurologist will be around 27 or 28 years of age before he leaves the embryo stage. At the end of that time he is advised to embark upon a period of foreign travel or of research. A hard apprenticeship indeed, but one that is necessary if the prestige of consulting neurology is to be maintained in international medicine. No discipline has yet suffered from the austerities of its regime, and the best types of anchorite will not be deterred by exacting conditions of entry or pupilage.

The committee in its report has not attempted to grasp the nettle of the future relationships with neurosurgery, though a period of six months as a whole-time house officer in a neurosurgical department will be accepted as part of the 18 months' compulsory service in clinical neurology. It does not favour a statutory register in present circumstances. Neither does it approve the creation of a special diploma in neurology, the consultant status of the neurologist being secured, it is felt, by a higher qualification in medicine. That financial assistance may well be required from official sources to maintain the neurological apprentice is fully appreciated by the College committee.

DELAYING EXCRETION OF PENICILLIN

One of the great handicaps of treatment with penicillin is its rapid excretion, which necessitates frequent injections and uses up much material. Various ways of circumventing this have been described, especially methods for delaying absorption from a subcutaneous site by mixing the penicillin with oil or by causing local vasoconstriction by adrenaline or by ice. Recently it has been reported by Beyer and his colleagues[1] that the action of penicillin can be prolonged by delaying its excretion through the kidney by the simultaneous administration of *p*-aminohippuric acid. Dogs were given a continuous intravenous infusion of 2.25% solution of aminohippurate at the rate of 3 c.cm. a minute, and a single intravenous injection of 10,000 units of penicillin. The concentration of *p*-aminohippuric acid in the plasma was 30 to 50 mg. per 100 c.cm. By this means the duration of detectable penicillin in the blood was almost doubled (4 hours instead of 2½ hours), the level was materially raised, and the amount excreted in the urine was correspondingly diminished. In later experiments[2] a mixture containing 5 units of penicillin per c.cm. and 1.5% sodium *p*-aminohippurate was given by continuous intravenous infusion for over 48 hours. The plasma concentration of penicillin was 2½ to 4 times as great as it would have been in the absence of aminohippurate. Beyer and his co-workers believe that penicillin is actively excreted by the tubule cells of the kidney and that this excretion is partly inhibited by aminohippurate. *P*-aminohippuric acid is said to be comparatively innocuous, and large amounts can be given without producing toxic symptoms.

Clinical trials of this procedure have been reported by Loewe and others.[3] They were treating patients with penicillin by continuous intravenous drip, and *p*-aminohippurate was given by the same means in doses up to 100 g. a day for periods of eight days. In most of the 50 patients this dose of aminohippurate produced only a low concentration of the compound in the blood (less than 10 mg. per 100 c.cm.) and there was no effect upon the blood concentration of penicillin. But in eight patients the blood concentration was greater than 10 mg. per 100 c.cm.; and in these the blood concentration of penicillin was increased three- to six-fold. Thus Loewe and his colleagues confirm in man the results obtained by Beyer and his colleagues in dogs; but at the same time they point out the difficulties in the way of successful clinical application. To maintain an adequate blood concentration of aminohippurate—e.g., 30 to 45 mg. per 100 c.cm.—it would be necessary to give 245 g. intravenously in 24 hours. No toxic effects were observed in any of the patients; nevertheless these amounts seem very large for a treatment which is only supplementary to another treatment.

The various devices for overcoming the rapid excretion of penicillin are ingenious, but they all introduce furthe complications into the treatment of the patient. The ideal solution of the problem is either to improve the supply of penicillin until it is plentiful and cheap enough to give by mouth regardless of waste, or to discover some derivative of penicillin with the same antibacterial action combined with more satisfactory pharmacological properties.

CYSTOMETRY

Cystometry is a comparatively new procedure, but one which is proving to be of increasing value as its application is more widely understood. Cystometry is much more than the mere measurement of bladder capacity, as the word seems rather to suggest; its usefulness lies in the practicability of making simultaneous measurements of capacity and intravesical pressure. From a study of these much can be learnt about normal bladder function and micturition—a subject which in man is still imperfectly understood. Moreover, nervous disorders affecting the bladder can be investigated with a completeness which has hitherto been notably lacking. In a recent article David Band,[1] after summarizing the accepted views on normal bladder innervation and micturition, describes the results obtained by cystometric studies in a series of cases of nerve disorders, including partial lesions such as transverse myelitis, and complete lesions where there is destruction either of the spinal cord or of the conus or corda equina. He shows how such examinations may not merely add to our knowledge of bladder function, but may also help the patient to live more comfortably. Of perhaps more general interest are the cases described of frequent or urgent micturition and enuresis typically met with in young patients who display no other neurological imperfections. Many officers, both medical and non-medical, have met with examples of this disorder during the war among young soldiers anxious to fight and psychologically normal. Cystometric investigations show that these patients have not got normal bladders. Clearly they deserve much sympathy and careful attempts to cure. The malingerer can quickly be detected. Band shows that ephedrine, by stimulating the sympathetic nerves of the hypogastric plexus, damps down the overactive detrusor muscle, and therefore may cure enuresis in selected cases.

The apparatus for cystometry is somewhat cumbrous and complicated, and, if unnecessary risks to the patient are to be avoided, should be used only by an expert.

NUTRITIVE VALUE OF FOODS

Nutritive Values of Wartime Foods (tables compiled for the Accessory Food Factors Committee) has been issued by the Medical Research Council as War Memorandum No. 14 (H.M.S.O., 1945, 1s.). Practically all of the 298 foods of these tables are peacetime as well as wartime foods, and it is highly desirable that the few exceptions such as "cod-liver oil, Ministry of Food" and "orange juice, Ministry of Food" should long be available as products of known and reliable potency. Thus the memorandum will be useful for long after the end of the war to all who desire to assess the values of the meals they eat or provide. For each food the average contents of water, protein, fat, carbohydrate, calories, calcium, iron, vitamin A (i.u.), vitamin B_1 (μg.), vitamin C (mg.), and wastage (%), are given per 100 g. of the edible portion. Individual samples may vary widely from these figures. Vitamin D (i.u.) and riboflavin (μg.) values per 100 g. of edible portion are given for certain foods. Probably all the likely sources of vitamin D have been examined, but it is fairly certain that many good sources of riboflavin will yet be discovered. Additional tables give the composition of foods "as purchased" per 100 g. and per oz., which will save the busy housewife some weighing in her own kitchen and also some arithmetic, but it will give her a less accurate estimate of the value of her meals. The memorandum is well printed, but the paper cover will withstand very little handling in either office or kitchen.

THE EXCEPTIONAL CHILD

Six papers are published in a report of the tenth conference on the exceptional child held in Baltimore by the Child Research Clinic of the Woods Schools, Langhorne, Pennsylvania. Those engaged in psychotherapy must remember that the mental health of a person cannot be gauged except in relation to the people round him; that a child never remains static, for both he and his behaviour are constantly changing; nor can mental health be divorced from physical health, and vice versa. "Psychotherapy should aim at making it possible for a particular patient to live within the limits of his equipment with other people, maybe with all other people, maybe with just a few other people, happily and without making a nuisance of himself." Most important in the child's environment is the mother, and she often needs treatment, not only advice, just as much as the child does. Until both are treated she will not enjoy the security which she can pass on to the child. Play is the normal method of expression for the child, and this can be used in elucidating his problems. A special technique is described called "the play-interview," in which the child is encouraged to carry on conversations between two or more dolls, thus revealing to himself and to the doctor the nature of his difficulties.

The educationist can take a hand in the problem of delinquency. The setting regarded as desirable to enable this to be done to the full is described, as are the methods whereby the retarded can take their place in the social complex. It is remarkable how often the parents of retarded children harbour a sense of grievance and guilt, and for their own sake and that of the child it is very necessary that such feelings should be removed by appropriate treatment. It ought to be remembered, however, that the vast majority of the people in the world are average and normal. A child's character and behaviour are largely influenced by the habits and convictions of the parents, but these in turn are determined by the attitudes of society; and it is most encouraging to know how quickly and completely social attitudes and habits can change. The true deviate alone cannot be influenced, and these abnormal personalities should be recognized. Sometimes the child is the deviate, and no treatment improves him, but sometimes a child who is really average, and therefore malleable, is brought for treatment by a parent who is a deviate and who cannot and will not allow the child to develop normally.

Two articles on the mite-borne disease commonly called scrub typhus—tsutsugamushi disease—appeared in the *Journal* of July 28: one on scrub typhus as a war disease by Major-Gen. Sir John Megaw, and the other a clinical study by Lieut.-Col. M. C. Menon and Capt. Colin Ibbotson. At that time the war with Japan had not come to an end, and it was forbidden on security grounds to mention that a successful prophylactic vaccine had been discovered and that at the request of the War Office the Ministry of Supply had undertaken to organize the production of this vaccine on a large scale for inoculating our troops in the Far East before the worst season of the year was upon them.

DOMICILIARY MIDWIFERY AND THE FAMILY DOCTOR

BY

DAVID DALE LOGAN, D.S.O., O.B.E., M.D., F.R.S.Ed., F.R.F.P.S.G., D.P.H.

B.M.A. Representative on the Central Midwives Board for Scotland

AND

ENEAS K. MacKENZIE, M.D., J.P.

Late Examiner, Central Midwives Board for Scotland

Doctors all over the country are perturbed by the recent report of the Royal College of Obstetricians and Gynaecologists, whose findings obviously point to the establishment of a specialist midwifery service in which the general practitioner would be excluded from midwifery practice unless his qualifications conformed to conditions, not laid down by the General Medical Council, but by the Council of the College. They ignore an issue which has not so far been effectively put before the medical profession—namely, the proper position of domiciliary midwifery in the proposed National Health Service.

The whole position of domiciliary midwifery has in recent years been obscured by the housing shortage. The increased hospitalization of expectant mothers within this period is regarded by most obstetrical specialists as due to an increasing desire on the part of pregnant women for hospital care during their confinement and post-natal period; whereas a very large proportion of the women who have had experience of both hospital and domiciliary care would prefer the latter had they proper homes to live in. Much done in medicine to-day ignores the patient as an individual and the vital importance of his or her environment. Those ignorant of general practice fail to realize the reactions of the latter upon the individual and upon the family. The following article has been written in support of the doctors in the country who are doing domiciliary midwifery, and who wish not only that they themselves should continue but that their successors should continue what they regard as the most important part of general practice. We have also tried to show that many of the adverse criticisms of our work as practical obstetricians has not the support of recent investigation.

For a number of years, owing to the rapid development of the public health service, local authorities and many specialists have come to think only in terms of institutions and clinics and have failed to appreciate the basic fact that a successful health service must centre round an efficient general medical service. In no department of medicine is this latter fact more evident than in the practice of midwifery, where, with the general practitioner as a centre, you have on the one side the midwife, the district nurse, and the health visitor, and on the other the specialist and the maternity hospital; the combination of all, as illustrated in the terms of the Maternity Services (Scotland) Act, 1937, produces the ideal maternity service.

The provision of better trained and more efficient nurses, the facility of transport, and the prevention of complications by more careful ante-natal examination, have in recent years diminished the dangers and sufferings of pregnancy and labour, and, while reducing the anxiety of the midwife, family doctor, and specialist, have increased their capacity not only to deal with normal maternity cases but to anticipate complications, and overcome difficulties to the ultimate advantage of mother and baby. Under the Maternity Services Act the family doctor has already realized that the more careful and skilful his ante-natal examination is the less trouble he has at the confinement.

Maternity practice is the very root of general practice; it produces the bond which unites the home with the family doctor, and the knowledge gained by the practitioner as family doctor not only compels him to see a maternity case in its true perspective, but is one of the main guides in ante-natal diagnosis towards a realization of his own capacity and his own limitations. To the obstetrical specialist the maternity patient is often little more than a case; he fails to realize that successful midwifery can be based only upon a co-operation between every factor which has for its ultimate aim the safety of mother and child. No clinic can take the place of the family doctor.

Exaggerated Fears

The dangers and difficulties of midwifery practice have of late years been magnified out of all proportion by specialists and public health officials. We contend that successful midwifery depends upon a sense of confidence and an absence of fear in the mind of the prospective mother. In the Scottish Report on Maternal Morbidity and Mortality, page 24, it is written: "There has been an unfortunate tendency of late to over-emphasize the dangers of child-bearing, and it is desired to take this opportunity to stress publicly the facts that pregnancy and parturition are natural physiological processes, and that departures from the normal occur only in a small proportion of cases. It is difficult to assess the reactions caused in women by fears unnecessarily aroused by indiscreet public emphasis upon accidents of child-bearing. There is no suggestion that scientific inquiry should be discouraged, but it is believed that disproportionate publicity of untoward results may itself aggravate a problem already sufficently difficult." A resolution in practically identical terms received the approval of one Representative Meeting of the B.M.A.

The case against the general practitioner's ability to practise midwifery successfully was based on evidence much of which has been proved wrong. The old belief that he is the main agent in spreading infection was long in dying; indeed there are still medical officers of health who have little knowledge of midwifery who hold this view. No reliable evidence is now put forward to support their case against us. In the large majority of domiciliary midwifery cases puerperal sepsis is infrequent, in spite of the fact that the family doctor is daily in contact with all manner of infectious diseases. On the other hand, such diseases as mastitis, phlegmasia alba dolens, etc.—diseases contracted as a result of labour or early in the puerperium, but which come to light some eight to ten days after the confinement—are much more common in hospital practice than in general practice. Want of an efficient system of follow-up prevents this fact being brought home to hospital staffs.

Use and Abuse of Forceps

It is, unfortunately true that in the early years of the twentieth century there was too much "meddlesome midwifery." All are agreed that forceps were frequently used when they should not have been. As a result of a campaign against this evil, in which the general practitioner received much abuse from certain specialists, many go to the opposite extreme and fail to use forceps when their use would save suffering and even the loss of infant life. No experienced general practitioner would permit a prolonged second stage of labour when the suffering, supervention of shock, and trauma of the mother, perhaps her life, and the life of the infant could be saved by a few minutes' skilful use of forceps. Not long ago a general practitioner objected to the use of the word "interference," writing that "skilled conduct of midwifery is the ability to use skilled scientific methods when required." The experienced general practitioner has to tackle many cases which are beyond the capacity of the midwife, outside the sphere of the specialist, but which he is quite capable of dealing with successfully. Some time ago Dr. W. H. M. Wilson pointed out in these columns that the impaction of the head in the middle of the birth passages was a common cause of delay in labour, and that if this were realized "the conservative use of forceps would be an everyday matter and not a cause of horror, as it seems to be." He further wrote that "the country practitioner is now, as he had always been by force of circumstances, the acknowledged expert in cases which, without being abnormal, are really difficult."

Until quite recently injuries, particularly tears of the cervix, were put down to "meddlesome midwifery and hastily conducted labours," and, of course, the general practitioner had to shoulder most of the blame. Investigation has now proved that a very large proportion of tears of the cervix are the result of the forces of an uncontrolled Nature. Many of these tears are due to neglect to give analgesics when the os is dilating. In England, under the Midwives Acts, this is very common, but it is less common in Scotland where the doctor is in control of the case. A drug such as pethidine will help to relax a cervix early in labour and thus prevent its injury;

an anaesthetic with manual or instrumental help will save many a perineum. Midwives in Scotland under the Maternity Services Act are much more likely to send for the doctor to repair a torn perineum than are midwives in England; where the ridiculously low figures recently published for perineal tears in cases conducted by midwives make it clear that the latter are not sending for the doctor when they should. Under the Scottish Act the services of an anaesthetist are provided; this guarantees that in extensive tears repair will be more efficiently done.

Ante-natal Care

A big percentage of doctors were doing a large amount of ante-natal work long before this was undertaken by special clinics. Under the Maternity Services Act all medical practitioners are expected to carry out a minimum of three ante-natal examinations in every case they book. The public are becoming much more alive to the importance of ante-natal examination, and within two years of the inception of the Act the medical officer of health of Lanarkshire was able to report that 95.3% of mothers within his area had received ante-natal care.

The ideal place for ante-natal examination is the home of the patient or the surgery of the general practitioner. There is a real danger in the ante-natal clinic. In many cases the patients are scared by their waiting-room companions before they enter the clinic proper; when there, the listening to discussions between physicians, nurses, and students often adds an alarming element of dread to the thought of the coming confinement. It is wrong to discuss ante-natal findings and their possible treatment before prospective mothers, especially primiparae. Ante-natal examination calls for experience and skill, and, as one writer put it, "patients must be individualized in regard to diagnosis and treatment . . . there should be no such thing as mass production."

The purposes of ante-natal examination are to determine the fitness of the patient to carry on with her pregnancy, to educate and reassure her, to diagnose the relationship between her and her infant, and, within the bounds of possibility, to foresee the nature of the confinement and determine whether the case can be dealt with at home or should go to hospital. As in the case of all beneficent advances in medicine, ante-natal care carries with it certain dangers. It has been proved that among a considerable number of the younger, inexperienced obstetrical specialists the ultimate effect of various findings tends to be exaggerated, patients are alarmed, the power of Nature to overcome difficulties is forgotten, and measures are taken which may result, and have resulted, in the loss of maternal and infant lives where, had the case been left to Nature or in the hands of a general practitioner, all would have been well.

For some years the widespread and unnecessary use of Caesarean section or of induction of labour for difficulties which Nature herself, or the general practitioner in the quiet of the patient's own home, could overcome led to protests from influential quarters. Dr. Bright Bannister (1935) wrote "that the operation of Caesarean section occupies an unjustifiable position in obstetric practice to-day, that the incidence of the operation is far too high, and that it is attended by a mortality which makes it suspect among measures that should have for their aim the diminution of maternal mortality." Prof. F. J. Browne (1934) was equally emphatic when he wrote that "no one will deny that much of this intervention is unnecessary" and added, "I believe I am justified in saying that ante-natal care has often simply transferred mortality from one column to another."

Whether we have to deal with a case of toxaemia, disproportion, hyperemesis gravidarum, heart disease, or any of the other complications of pregnancy, no one is so fitted as the family doctor, knowing as he does the personal and family history of the patient and the patient's home conditions, to determine whether the case should be dealt with by himself and in the patient's own home or transferred to hospital. The most careful and experienced, be he general practitioner or specialist, can make an error of judgment in midwifery practice. This does not happen in the commoner difficulties, but in sudden and unforeseen emergencies; and even in the big majority of these cases the specialist can be called to the home of the patient and, with the assistance of the family doctor and nurse, deal successfully with the case.

It is possible that much of the present urge for institutional treatment is a passing phase and depends in large measure on the wretched housing of the majority of our working people. Hospitals we must have, but the ideal midwifery of the future must be based upon the principles which form the foundation of the Maternity Services (Scotland) Act, 1937—that is, close co-operation between general practitioner, midwife, specialist, and hospital.

Relief of Pain

The relief of pain in labour is of supreme importance to a large percentage of parturient women. It is the psychological build of a woman which determines her appreciation of pain, and from this point of view the family doctor, with his previous intimate knowledge of the woman, is in the best position to decide when an anaesthetic should be administered. In Scotland and England under the Midwives Acts midwives were discouraged from sending too often for the doctor. The Maternity Services (Scotland) Act recognizes the importance of relieving pain; the services of an anaesthetist, if necessary, are provided. In England specialists are advocating that midwives should have permission to administer anaesthetics; in Scotland we hold—and we are supported by the B.M.A.—that no midwife should be allowed to administer an anaesthetic without a general practitioner being present. It is very gratifying to note that in England, where in the past the relief of pain in labour was less considered than in Scotland, the insistence of the patient on obtaining relief of pain is resulting in more frequent calls by the midwife on the doctor.

There is no one in a better position to give valuable information regarding maternity nursing than the G.P. His opinion is never sought. It would be well were the Council of the Royal College of Obstetricians and Gynaecologists to appreciate the fact that a registered medical practitioner is a practitioner, and a registered nurse is a nurse, and apply this knowledge to the practice of domiciliary midwifery.

Queen's nurses have for many years, under the direction of the family doctor, conducted midwifery in the most satisfactory way, with efficiency, tact, and discretion. The outstanding feature of their service is the traditional co-operation between nurse and doctor. The midwife who has had a general nursing training has also these qualifications. In the training of midwives there is great need for instruction in ethics in order to impress upon them the importance of avoiding idle talk and discussing the condition of their patients with them. A patient must have perfect confidence in her nurse as in her physician. The longer a midwife remains in a district the better, for she gets to know her patients and they come to have confidence and trust in her. Local authorities tend to think too much in terms of institutions and too little in terms of the mothers' own homes, with the result that the changes of nurses are too frequent.

In maternity practice midwives do not seek medical aid sufficiently early and often. A nurse should realize, especially in cases of primiparae, the importance of sending for a doctor early in labour. When the os is dilating the doctor is able to lessen the patient's pain without injury to the foetus, and also to lessen the chance of injury to the cervix; he is able to allay the fears of the patient and her relatives and to guide and encourage the midwife.

The Teaching of Midwifery

Howat in the *Lancet* (1938), in discussing the many conflicting theories in well-known textbooks, remarked: "With teaching so copious, so various, so conflicting, confusing, and mistaken, choice is wide and perplexity almost inevitable. In fact, it is not so much the fault of the general practitioner that his obstetrical skill is under a cloud as the fault of his teachers. . . . Their published writings go to show that British teachers of midwifery to-day, almost without exception, hold and teach not that normal parturition is a normal function to be naturally performed so long as it progresses normally, but that it is a process calling for active interference." We might add that in many teaching centres students are strongly advised, in cases where there is the slightest deviation from the normal, either to call in a specialist or to send the patient to hospital. Such is the modern training.

General practitioners who, during the past ten years, have read articles upon midwifery, followed discussions upon ante-natal care, etc., and appreciated the conflicting views expressed are not surprised to find that some obstetricians are uneasy about their ability to teach midwifery successfully to their students. Happily physicians have not the same feeling about their teachers of medicine and surgery, and yet, after all, a much greater part of their surgery work requires reference to a specialist. The obstetrical specialist and the G.P. always approach the subject from a different angle. General practitioners as a body are very conservative, and this has been their salvation, or rather the salvation of their patients, when faced with the ever-changing teaching of the specialists.

According to some obstetrical specialists the perineum is a danger spot which must not be touched during the course of labour; vaginal examination is almost an obstetric crime. We general practitioners examine our patients per vaginam as often as we think necessary, and it is comforting to be told by a well-known obstetrician that he has still to be convinced that digital vaginal examination is a danger to a woman in labour, and that "he was prepared to argue that anyone who has not sufficient knowledge to make an examination in a surgically clean manner has no business to attend a confinement." Within recent years no new era has dawned upon hospital and specialist obstetric practice, the outstanding factors in the reduction of maternal mortality being sulphanilamide therapy and blood transfusion.

By far the best method of learning midwifery practice for both doctors and nurses is the direct one—that is, to sit at the bedside of a woman in labour. Attendance at many normal labours is of the greatest help when it comes to tackling the difficult and abnormal case, and it would assist the hospital specialist and hospital practice if the specialist gave more attention than he does to the normal and itched less to interfere with the course of Nature. We would like to point out to those obstetricians who have been so prominent in belittling the general practitioner's ability to practise midwifery successfully that they would have gained considerably in manipulative skill, and also gained a real knowledge of the parturient woman, if, before they had specialized, they had spent a few years in general practice. Then they might have appreciated the many difficulties the family doctor encounters in his daily work.

Conclusion

We would assure Mr. Eardley Holland (vide *Practitioner*, January, 1945) that the team-work upon which, he contends, the successful practice of modern midwifery depends will be found in Scotland where the Maternity Services (Scotland) Act, 1937, is in operation, and that there is no tail. This Act has changed the whole future of maternity practice in Scotland, and England would be wise to follow our lead. It is hardly necessary to add that in the proposed National Health Service the maternity services would not be under the direction of the local authority. The psychological effect of the presence of friendly and sympathetic people in familiar surroundings upon a woman in labour cannot be overestimated. Domiciliary midwifery, with the woman in the hands of a doctor and nurse in whom she has confidence, is safer for mother and infant, in all but a small minority of cases, than institutional midwifery. When the housing shortage has been remedied there will be a great increase in domiciliary midwifery to the advantage of the whole country.

Finally let us quote two outstanding medical women. Dame Janet Campbell writes: "No woman ought to lack, on account of poverty, anything she needs during childbirth. The great thing is to make midwifery in the poorer houses sufficiently attractive for the family doctor to take it up and study it more closely." This has been done in Scotland. Dame Louise McIlroy writes: "There were those who considered that the mothers of the country would be best served by a whole-time midwifery service, and the general practitioner would have to go, but it seemed a pity, for the general practitioner provided a human element lacking in a different service. Take prevention, which was the slogan of legislators; there was no one more capable of instituting preventive measures than the family doctor. He was the first line of defence, knowing the family and its circumstances, treating the little ailments of the prospective mother, and forestalling complications."

AGENDA FOR PLANNING LONDON HOSPITALS

KING EDWARD'S FUND PROPOSALS

Yet another report on London hospitals, this time the work of a joint committee of King Edward's Hospital Fund for London and the Voluntary Hospitals Committee, makes its contribution to the solving of the largest if not the most difficult of hospital planning problems. It runs parallel with the recent survey of hospital services by Dr. A. M. H. Gray and Dr. A. Topping (reviewed in the *British Medical Journal* of July 14, p. 56) and reaches substantially the same conclusions.

It is now generally recognized that the hospital services of London cannot be planned without taking into account the extent to which the Home Counties look to London for hospital facilities. Before the war about 40% of the patients treated in the voluntary hospitals of London came from outside the County of London boundaries. There is a continuing tendency for the London population—its industries as well as its homes—to move outwards; means of transport between the centre and the periphery have improved out of all knowledge; but hospital provision has not shared this tendency to any great extent. Even if, in future, large additional hospitals are put up in the outer areas the great hospitals of Central London will still be looked to for highly specialized services.

The area of London and the Home Counties must, therefore, be planned as a whole. It can be divided roughly into three zones: the central area with a heavy concentration of beds and a declining residential population, the industrial and dormitory area with a shortage of beds and a rapidly increasing population, and the more rural areas centred on local towns. The hospitals in this great region vary much in size and function. The local authorities have a number of large, up-to-date, and well-equipped hospitals side by side with old-fashioned and unhygienic institutions still administered under the Poor Law. On the voluntary side there are hospitals ranging from the very largest to small ones of 60 beds or so, which, however, have been classed as general rather than as cottage hospitals.

Hospitals in Transition

The report discusses the transition from the cottage to the general hospital. Such a transition implies that the general hospital will lay itself out to deal with the whole range of "acute" work likely to arise in its locality. It must provide a consultant staff with clinical responsibility for the patients under their care, a resident medical staff, a nursing staff of the required competence, all proper ancillary services, out-patient clinics, and the commoner special in-patient departments, such as ear, nose, and throat. Efficiency demands a bed complement somewhere in the neighbourhood of 150, and a hospital with 150 beds should afford sufficient work to warrant the employment of at least three resident medical officers, in addition to one or more registrars.

> "It would . . . make for progress if it were recognized that a hospital with less than 150 beds—other, of course, than a cottage hospital staffed by general practitioners—is unlikely to be able to provide a complete service; and should therefore be regarded as in a state of transition, and as not yet having fully attained to the status and responsibilities of a general hospital."

It is common ground that it is not yet practicable to propose that all the members of staffs of the smaller general hospitals, and even of some larger hospitals in the Home Counties, should be consultants, giving their whole time to general medicine or surgery or to a specialty; but it is desirable, say the authors of this report, that in future such appointments should be restricted to practitioners who have served for a period of not less than two years in a hospital or unit devoted to the special work they propose to undertake.

Is there an economic size for the larger general hospital? Would it be wise to encourage the ultimate development of voluntary general hospitals to a size approaching that of the average local authority hospital? There has grown up in recent years a belief that a large hospital, say of 700 or 800 beds, is *per se* more efficient than a small hospital. Undoubtedly that is true in some respects, but the authors of this report are of opinion that the argument in favour of the large hospital may be carried too far, and that the case for the small general hospital rests on much firmer ground than appears at first sight. By "small" anything under 700 beds is meant.

A Plea for the "Small" Hospital

The smaller hospital has certain advantages over the large unit: it serves a more local population; it is well known to its patients; and it can more easily ensure a friendly and personal atmosphere, which means much to the sick person.

> "We do not believe that the voluntary hospital is called upon to compete with the local authority hospital in size, and we think there would be a real danger of voluntary effort failing to make its special contribution in terms of quality of service if too ambitious a programme were undertaken with the help of public monies."

In the Central London area it is considered that there is little justification for general hospitals of fewer than 100 beds. These hospitals might well join forces with each other or with a larger neighbour, with the ultimate object of a physical amalgamation; but in industrial and dormitory areas the elimination of the smaller hospital would be a serious loss to the life of the communities. Perhaps in time these hospitals might develop into large hospitals providing a comprehensive service.

In the outermost zone of the London and Home Counties region the hospitals are mainly located in towns of medium size, and they serve rural areas. The majority of the voluntary hospitals are of the cottage type. It is urged that there should be a full acceptance of the difference between a general and a cottage hospital, the upgrading of all those units where circumstances justify the development into a general hospital, and an overhaul of consultant medical staff in such a way as to bring a regular system of visiting of cottage hospitals by consultants into the realm of practical politics. It is considered that a working arrangement between the voluntary and the local authority hospitals would be greatly facilitated if they shared to a certain extent the same consultant staff. Moreover, the appointment of the same consultant to two or more hospitals in the same area would probably provide him with sufficient work to make it worth his while to live in the neighbourhood.

For cottage hospitals the report lays it down that any such hospital with 50 or more beds should have a resident medical officer. Beds at a cottage hospital should be available to all general practitioners in the neighbourhood, subject always to the approval of the committee of management. Other recommendations concern special hospitals, which play an important part in postgraduate education and in research; the provision of accommodation for the chronic sick; and the establishment of out-patient departments and an ambulance service.

The authors of the report are critical of the proposal of a central bureau for controlling admissions. Such a plan would be contrary to the principle of free choice of hospital. The more important step would be to raise the standard of medical and nursing care in those hospitals in which it is unsatisfactory, so that they would attract more cases, and the unwieldy waiting-lists attaching to some hospitals would be diminished.

The report is printed and published by Geo. Barber and Son, Ltd., Furnival Street, London, E.C.4, price 1s. post free.

COURSES IN HOSPITAL CATERING

The Nuffield Provincial Hospitals Trust has taken the lead in initiating, as an experiment, refresher courses in catering at three Provincial centres. These courses are to be held at Birmingham, Leeds, and Wolverhampton, where the Boards of Management of the Birmingham United Hospital (Queen Elizabeth Hospital), the General Infirmary at Leeds, and the Royal Hospital, Wolverhampton, readily agreed to co-operate and are making available all the necessary facilities and the staff required for the conduct of the courses.

This development in the Provinces follows the successful results of the course at the London Hospital arranged by King Edward's Hospital Fund for London. The syllabus for the courses includes lectures and demonstrations, classification of foods, administration of food and catering departments, buying and ordering, special diets, menu planning, cooking and serving of foods, rationing, and allowances. The planning of the courses has been undertaken by the responsible officers at each of the hospitals, and they have had the advice and assistance of Miss Rose Simmonds, chairman of the British Dietetic Association.

The courses, each consisting of six sessions, are open to administrators, matrons and assistant matrons, dietitians and catering officers, stewards, housekeeping sisters, and cooks of hospitals in the areas adjacent to each of the three hospitals mentioned above, and no fee is required of those attending. The Wolverhampton and Birmingham courses begin on Sept. 11 and 15 respectively; the one at Leeds opened on Aug. 14.

TYPHUS FEVER PANEL

In February, 1942, reference was made in these pages to the establishment by the Ministry of Health of a Typhus Panel. The lack of opportunity for the medical profession in this country to become familiar with typhus fever has not infrequently resulted in a mistaken diagnosis. In the circumstances, a panel of 8 to 10 consultants established in different parts of the country was formed. Gaps have now appeared in this panel, and the Chief Medical Officer of the Ministry of Health would be grateful to hear from medical men who have had the necessary clinical experience and who are willing on occasion to assist in the diagnosis of typhus in the districts in which they live. A fee of 5 guineas and out-of-pocket expenses will be paid by the Minister if and when a member of the panel is called upon to act. The consultant is required to provide the Minister with a written report on each case seen.

APPOINTMENT OF REGISTRAR-GENERAL

The King has approved the appointment of Mr. G. C. North, *M.C.*, LL.B., a Principal Assistant Secretary in the Ministry of Health, to be Registrar-General upon the retirement, at the age of 65, of Sir Sylvanus P. Vivian, C.B., on Sept. 30, 1945. Sir Sylvanus Vivian has been Registrar-General since 1921. He began his career in the Inland Revenue Department in 1903. In 1913 he was Assistant Secretary to the National Health Insurance Commission, and during the last war served in both the Ministry of Food and the Ministry of National Service. Mr. G. C. North joined the Ministry of Health in 1921, and has had wide experience of health and housing administration, including international health matters. He served as private secretary to Miss Susan Lawrence and Sir Edward Forber at the Ministry; Secretary, National Radium Trust, 1931-7; acted as secretary of various Departmental Committees, including the Advisory Committee on Water and the Advisory Committee on Therapeutic Substances; member of the British Delegation to the League of Nations Assembly, 1930; also worked in connexion with the International Health Office in Paris; Ministry representative on the Central Council for Health Education, and on the Executive of the National Federation of Women's Institutes.

The pamphlet, *Colonial Research 1944–5* (Cmd. 6663, H.M. Stationery Office, 6d.), includes the second annual report of the Colonial Research Committee, constituted jointly by the Secretary of State for the Colonies and the Medical Research Council, under the chairmanship of Sir Edward Mellanby, with Dr. W. H. Kauntze as vice-chairman and Dr. F. Hawking as secretary. No specific schemes for medical research involving substantial expenditure were before the committee during the year, but plans were made to continue studies on the bionomics of *Anopheles gambiae* in Sierra Leone and Nigeria, and for field trials of the insecticide D.D.T. Definitive reports on trials of D.D.T. in British Guiana during the year were not available, but preliminary accounts indicated that this material will certainly be a most important addition to the armamentarium of the malariologist, and may in fact prove to be the first really efficient means of controlling malaria in rural as well as in urban and closely settled areas. In the hands of workers in Africa, advised and guided by Prof. P. A. Buxton, it has been shown that D.D.T. is toxic to the tsetse-fly, the vector of trypanosomiasis. With regard to D.D.T. generally, the committee does not consider the promise shown by this or any other substance of like activity justifies as yet any relaxation of orthodox and tested antimalarial measures. Nor does it consider that there is any cause to relax efforts to increase supplies of quinine, which, despite the development of valuable synthetic drugs for the prevention and cure of malaria, remains of outstanding importance as the easiest and safest drug to use without close and constant supervision.

Correspondence

Ambulatory Treatment of Duodenal Ulcer in a Factory

Sir,—Towards the end of two years' enforced absence from general practice it was my good fortune to fall on a book, *Endocrinology in General Practice*, by William Wolf, M.D. On the subject of peptic ulcer he states, like most authors, that the pathogenesis of peptic ulcer is still undecided, but points to "involvement of the endocrine glands through the sympathetic nervous system." From these premisses he builds up his argument on a physiological basis as to the causation of peptic ulcer, and his conclusion seems justified. Further, he states that Metz carried out the treatment of peptic ulcer with posterior pituitary extract snuff with good results. To a sufferer of 20 years' standing, who had undergone an operation for perforation of the duodenum and who had consulted several specialists, it was a relief to know that at least there was a departure from the usual practice of treatment by rest, diet, and alkalis—a treatment which, like my fellow-practitioners, I had carried out for many years with very poor results. In my own case I had adhered rigidly to all medicines and diet prescribed, but even with that I had freedom from pain for only two or three weeks between attacks which lasted for two to three months. It was then I concluded that diet had little to do with the causation or treatment of peptic ulcer: rest I had in plenty, yet pain, sickness, and vomiting were my constant companions.

I began work again in May, 1939, and after having several severe attacks I started, in January, 1940, Metz's treatment with posterior pituitary extract snuff insufflation 50 mg. at 11 a.m. and 7 p.m.; diet was not restricted. I remained completely free from pain, sickness, and vomiting from January, 1940, to September, 1940, when I had an attack. I again commenced the "snuff," which cut short the period of two to three months to as many weeks. I remained free from attack until December, 1941. Again the remedy was taken with excellent results. In April, 1943, I was *x*-rayed and the report was "deformity of the duodenal cap." Since then I have had two attacks; in all, I have been off work for three weeks since 1939 with duodenal ulcer complaint. I trace the attacks to worry and chill and probably overwork.

From May, 1939, to May, 1944, my work consisted, in the most part, of the examination of men for His Majesty's Forces, and I had little opportunity for treating ulcer cases. In May, 1944, I took a position as medical officer to Scottish Aviation Limited, Prestwick Airport, Ayrshire, and was not surprised to find a big number of workmen suffering from duodenal ulcer and thereby losing much time. In October, 1944, I approached the directors, explained to them my own experience of duodenal ulcer, and asked for permission to treat the workmen. They were interested; not only did they grant my request but stated their willingness to bear the expense.

A number of men with duodenal ulcers proved by *x*-ray were interviewed, and it was agreed that treatment should be carried out, subject to the approval of their own doctors. Only a few withheld consent. The advantage of this ambulatory treatment is that it can be carried out while the men are at work. Each man was examined in the following manner: family history, past history, history of stomach complaint; and the effect of weather, worry, anxiety, fatigue, and fear. The different patients' systems were examined. In two cases organic disease of the lung and organic disease of the heart were found and their doctors duly notified. Treatment began on October 27, 1944. Treatment: posterior pituitary extract snuff 50 mg. at 11 a.m. and 7 p.m. by insufflation, to which I added half a grain of phenobarbitone half an hour before bedtime. The powders were given for 14 days and the pellets for 28 days. The histories were varied—the men had suffered from the condition for from 1 to 20 years, many had been discharged from the Services, many had histories of duodenal perforation, and most at one time had been in-patients. Treatment ended on April 2, 1945, and the results to the present show that, of 75 cases treated, 60 have had no pain. Two have been *x*-rayed; in one case "no duodenal ulcer was found" and in the other case there was "deformity of the duodenal cap."

It is reckoned that many hundreds of working hours have been saved by this treatment. My purpose in making this report now is that, owing to the possibility of my losing some of my patients through their return to peacetime occupations, I availed myself of my present opportunity of having their reports while they are still with Scottish Aviation Limited.—I am, etc.,

Prestwick Airport, Ayrshire. John Stevenson.

Treatment of Infective Hepatitis

Sir,—We have followed with interest the recent publications on the use of choline and methionine in the treatment of hepatitis and jaundice, and we wish to put forward certain points about the dosage. That the substances are lipotropic and that they can exert a curative effect on certain types of liver pathology is certain, at any rate so far as animals are concerned. The use of these substances in man does not appear to have met with the same success, few of the investigators suggesting more than slight statistical evidence of improvement. We suggest that these results should not lead to abandoning the use of the substances but to a more careful metabolic assessment on an increased dosage.

It may be of interest to compare the dose used in these trials on men with those which have proved effective in animals. In animals in order to prevent the appearance of a fatty liver methionine should be given in doses of 20 mg. per kilo body weight. Choline appears to be effective in the same dose (Frame, 1941). For a man of 70 kilos it would appear that 1.5 grammes per day of either substance is the minimum prophylactic dose. The point to be stressed, however, is that these are prophylactic doses: the curative dose of choline is 3 to 4 times larger—70 mg. per rat per diem according to Best and Huntsman (1935). Experimental evidence is lacking on the curative dose of methionine. If this is assumed to be either equivalent to choline as in prophylaxis, or on the basis of methyl groups three times greater, then the curative dose in man would be 20 grammes of choline a day for two or three weeks, or 20–60 grammes of methionine a day for a period as yet undetermined.

Beattie (1944) gave methionine intravenously in 10-gramme doses with some success, and we have been using similar amounts of either methionine or choline. The intravenous route was selected because oral administration may lead in some cases to sickness (Higgins *et al.*, 1945; Albanese *et al.*, 1944), and also to ensure complete absorption. Spill-over by the kidneys is only small. We have found that the total loss of unchanged methionine in the urine is only about 70 mg. per dose.

Using doses of this size leads in nearly every case to ketosis; the ketone being acetone and β-hydroxybutyric in the case of methionine, and an unidentified ketone or aldehyde in the case of choline. The presence of these ketones would suggest increased fat embolism. In patients with existing albuminuria both substances lead to its decrease or disappearance, although it should be noted that in normal men the same dosage of methionine actually leads to albuminuria.

We are reporting elsewhere the results of our experiments, but in two cases we have had results as dramatic as those reported by Beattie.

Since the results of clinical trials using small doses, statistical evaluation, and in many cases inadequate metabolic studies, have been generally inconclusive, your leading article (March 24, p. 415) suggests that the expense involved does not warrant the use of methionine in the treatment of jaundice. This conclusion might well lead to the abandonment of a life-saving measure in certain cases.—We are, etc.,

Acute Surgical Emergencies and Pulmonary Tuberculosis

SIR,—Patients having collapse therapy for pulmonary tuberculosis are, equally with others, subject to the risk of acute surgical conditions requiring laparotomy. If they are under care in a sanatorium the combined treatment can generally be achieved with adequate supervision, but in some cases where patients are admitted to a surgical ward in a general hospital it appears that treatment for the pulmonary condition is not maintained.

All sanatorium physicians have, from time to time, re-admitted patients after acute operations on the abdomen who have lost an artificial pneumothorax previously well established, with resulting reactivation of the tuberculous disease. As an example I may quote the history of a young woman with a left artificial pneumothorax, able to work, who developed an acute intussusception which was successfully operated upon in a general hospital many miles away. Unfortunately no attention was paid to the pulmonary disease; the pneumothorax was found completely obliterated on her next attendance, and the reactivated disease caused her death nine months later.

I would therefore urge that surgeons faced with such a situation should, as for an equal emergency, call at once for expert maintenance of the collapse therapy: house-surgeons are generally not competent to undertake this. The operation and the administration of an anaesthetic can cause a pneumothorax to be lost in a day, and the result may be ultimately as fatal to the patient as neglect of the surgical condition.—I am, etc.,

Clare Hall Hospital, South Mimms. F. A. H. SIMMONDS.

Treatment of Severe Paronychia

SIR,—The *Journal* of June 30 has just reached me, in which Drs. G. J. Grossmark and L. W. Plewes describe (p. 906) the treatment of hand infections with penicillin. I note that 14 out of 32 cases of paronychia had pus under the nail, and that the average time off work from the start of penicillin treatment was 12 days.

Recently at sea a rating reported with a severe paronychia about 12 hours old. Frequent hot bathing and poulticing during the next 12 hours produced a grossly swollen and painful terminal phalanx, with tense red skin all round the base of the nail and visible pus beneath it. This was clearly a case for the classical two lateral incisions and ribbon gauze under the flap, but such a procedure single-handed at sea is not always easy, and it was decided to try to drain the finger through the nail. A pointed wire 1/16 in. in diameter was heated and applied to the nail over the pus. The pressure caused some pain, but it was only necessary to heat the wire three times before pus welled up through the hole with instant relief. About six holes were thus burnt through (only the first was painful), and in all at least 1 c.cm. of pus was obtained. That night the patient slept well, and next morning the finger appeared much improved. A few of the holes were reopened and some more pus extruded; pressure on the skin proximal to the nail caused pus to appear, thus proving that the whole of the area was capable of being drained through the nail. Heat was applied during the second day, and by the third morning no more pus appeared and the finger was symptomless except for slight tenderness. By the fifth morning this rating was considered fit to return to full duty, including scrubbing out his mess, and there has been no relapse. No other form of treatment, except a sling, was used.

This most encouraging result, when successful, far surpasses any other form of treatment as regards simplicity, lack of pain and subsequent deformity, and quick return to work. This is the only case I have yet tried, and it may, of course, prove to be useless in others.—I am, etc.,

IAN G. WICKES,
At Sea. Surg. Lieut., R.N.V.R.

Penicillin for Massively Infected Tissues

SIR,—The following case of subcutaneous gangrene of buttocks complicating a horseshoe ischiorectal abscess may be of interest as a further example of the great part penicillin is playing in the treatment of overwhelming infectious conditions.

A heavily built plethoric man aged 61 was admitted to hospital on May 29, 1945, when he was rather confused, very toxic; temp. 101.6° F., pulse of poor volume, rate 110 per minute. The skin of his buttocks was green and necrotic, surrounded by a wide area of cellulitis, and foul-smelling pus oozed from two large and three smaller sinuses. Both ischiorectal fossae showed signs of abscess formation. The condition had apparently been present 14 days. Cardio-respiratory and other systems were normal for his age.

Under light gas-and-oxygen anaesthesia the ischiorectal fossae were incised and found to be involved in an enormous horseshoe abscess which had discharged under the skin of the buttocks. On incising the skin over the buttocks by joining the sinuses, great lumps of subcutaneous fat, which were green, gangrenous, and stinking, separated to expose the muscles of the buttocks. All this necrotic material was removed, the overlying skin, which was green and gangrenous, was also removed, but as much of it as possible was spared. A specimen of tissue was taken and tested for sensitivity of infecting organism to penicillin. On surveying the site of operation the buttocks presented a horrible stinking mass, glutei exposed, both ischiorectal fossae draining through large incisions, and in the middle a patulous anus. There was no fistula in ano present and the sphincter ani muscles were intact.

The patient was treated with penicillin 10,000 units three-hourly by intramuscular injection, as I did not consider the continuous intramuscular drip method suitable in this case in view of the filthy condition of his buttocks and thighs. In the meantime the causative organism was found to be a non-haemolytic streptococcus sensitive to penicillin. Four-hourly eusol dressings were applied locally, and within 48 hours the temperature was normal. The patient looked better, pulse was firmer, he began to eat, and was quite rational. From then on he never looked back. He remained incontinent of faeces for a month, but by the sixth week was discharged fit and well, the skin having grown in a most amazing manner to cover the buttocks completely.

I have previously been impressed by the remarkable power of regeneration which penicillin therapy confers on massively infected tissues. This was especially marked in the case of a woman with phagedaena vulvae treated conservatively with penicillin only by Mr. Emblin, surgeon to the General Hospital, Halifax, that patient too making a complete recovery with first-class anatomical and cosmetic result.

I wish to thank Mr. Haydon-Baillie, F.R.C.S., medical superintendent, for his advice on this case, and also Dr. Dunlop, who conducted the pathological investigations.—I am, etc.,

R. F. O'SULLIVAN,
R.S.O., County General Hospital,
Worksop, Notts.

Aspiration Test in Diagnosis of Breast Tumours

SIR,—Most of us will agree with Mr. M. D. Sheppard (Aug. 18, p. 231) that a diagnostic aspiration is a wise procedure in a doubtful breast tumour. Sometimes such a diagnostic aspiration may cure the cyst, and thus become a therapeutic aspiration. I have two patients who had cysts of the breasts aspirated two and three years ago, without recurrence up to the present time. Further, should a cyst recur after aspiration it is sometimes possible to cure it by a small injection of a sclerosing solution. One has to bear in mind, of course, that such treatment does not cure the underlying chronic mastitis.—I am, etc.,

Rotherham. ERIC COLDREY.

Emergency Treatment of Fractured Femur

SIR,—Vigorous criticism in the absence of direct observation is prone to inaccuracy. However, I was interested to read the remarks of your correspondent, Surg. Lieut. J. S. Joly (Aug. 18, p. 232), regarding an emergency treatment of fractured femur. It is equally probable that a short description will involve omission of details. As your correspondent states, it was possible to diagnose the fracture as being in the region of the greater trochanter. This was done. There was considerable shortening, and although I am not prepared to defend the ice-tong calliper as a form of extension, it is much easier to control than a Thomas splint. Conditions of lack of sepsis did not prevail. Your correspondent infers that an attempt was made to use the calliper with a Thomas splint; in fact, no such experiment was carried out.

The construction of the elevation apparatus is such that flexion of the knee is maintained until after the application of the plaster. The description of the procedure states: "As the application of the cast proceeded the skeletal traction was removed." The fracture was not displaced during the application of the plaster or at any other stage. The board extended from the patient's head to the level of the second lumbar vertebra. The perineal post is not attached to the board but to a narrow metal plate. The plaster is passed round the metal plate, which is slipped out afterwards. The whole purpose is to ensure continuity of extension so that traction shall be continued right up to and even during the first part of the time taken to apply the plaster.

As the condition of traction remains exactly the same, no displacement can occur and an anaesthetic is quite superfluous. In this case an anaesthetic was contraindicated in view of the patient's age—76 years. The plaster was applied from the level of the second lumbar vertebra to the knee on the affected side, as it was considered that the patient would wish to walk about again, and it was thought worth while to continue active and passive movements at the knee, which had been started two days after the Thomas splint had been removed and continued during the several weeks before the plaster cast was applied.—I am, etc.,

Scarborough. J. NOEL-JACKSON.

Removal of the Wrong Eye

SIR,—In the *Supplement* of Aug. 11 (p. 41) it is reported that Mr. Oswald Hempson made the following statement: "We have cases of forceps being overlooked, and occasionally cases so grave as the removal of the wrong eye. . . ." Mr. Hempson was speaking as a lawyer and his words imply that cases of removal of the "wrong eye" have occurred more than once within his own personal experience, or, at least, that he has definite knowledge of such cases. Would Mr. Hempson or any doctor who has met with a case of this kind be so good as to indicate where it has been reported in medical or legal literature? It is difficult to imagine that such a case could occur without being recorded in print.

It was always my habit when teaching to refer to the impossibility of such a mistake as one of the advantages of the use of local analgesia for the removal of an eye, but the removal of the sound eye was regarded as a hypothetical possibility rather than as an actual fact. I have never heard of a case. Has it ever happened or is it a myth? If it has not happened it is important that the public should not gain the impression from the medical press that it sometimes occurs.—I am, etc.,

Edinburgh. H. M. TRAQUAIR.

Jelly-fish Stings

SIR,—Dr. H. Muir Evans (Aug. 4, p. 165) quotes a description of a case occurring in the Tropics. Having personal experience of this unpleasant bathing incident on our own west coast, I think that a statement of my symptoms may be of interest, for since then I have held the view that many unexplained bathing fatalities in good swimmers may have been caused by this agency.

In 1902, when on holiday at Llandudno, I was beach-bathing; in those days a long diving-board on wheels enabled one to take a running dive into about six feet of water. I made a good dive, but before I had surfaced I felt an intense red-hot pain over the side of my neck and right supraclavicular region. Turning to swim in, the pain spread across my right chest and axilla and down my side and right arm, while I felt as though I were going to faint. By the time I had waded ashore, only a matter of some twenty yards or so, I felt nearly powerless with an agonizing sense of constriction in my chest, and just managed to get to my tent before my legs gave way under me. Though it was 11.30 a.m. on a hot summer morning I felt desperately cold and my teeth began to chatter. I looked so bad that my friends rushed to get brandy (procurable in those days!) and a doctor. Mercifully the former was quickly forthcoming, and its effect was to relieve to a great extent the feeling of respiratory distress, so that I was able to slip on some clothes and get the few hundred yards to my hotel, where I went to bed.

By this time the affected area of the skin was swollen and red with a few weals on my face and neck and below my deltoid, while the burning pain was intense. I experienced severe colicky pains and felt as though I were going to have diarrhoea and sickness. No doctor being forthcoming I prescribed another hot brandy and water, while my friend went to a local chemist for a lotion to soothe the skin. This was most efficacious, and the soporific effect of the unaccustomed brandy worked so that I slept till tea-time. On waking I still felt extremely weak, but could breathe without difficulty, all abdominal discomfort had disappeared, and I was quite ready for a wholesome tea with an egg. The friendly chemist, when issuing a further supply of the lotion, advised and handed out a rhubarb pill! I slept all night and woke feeling more or less fit, except for an intense irritation of the affected area of skin, which was still pink and had a few petechiae below the axilla on arm and side. This completely disappeared in two days, but I had a mild desquamation of the petechial area.

The interesting point is the extreme rapidity with which the poison produces such profound shock, for I was 18 at the time and as physically fit as it was possible to be; nevertheless I feel sure that had I been in deep water any distance from the shore I could not have made it without assistance. True, I gave myself a good dose of the poison by squeezing the jelly-fish between my arm and side, but this could happen to anyone doing an over-arm stroke. The jelly-fish was of the "frayed rope-end" type (*Medusa charybdiaedae*, I believe), and visitors to the coast, particularly in the west, will know that on some days the sea is alive with them, as they appear to drift in with certain winds on warm currents. They are bathing companions to be given a wide berth.—I am, etc.,

Amersham. H. J. HENDERSON.

Weight Reduction by Dieting

SIR,—I was interested in your correspondent "Apollonian's" starvation diet (July 28, p. 136), but feel that he might have achieved his object almost as rapidly and more advantageously without starvation. I have been able to achieve similar results while continuing to eat, in peacetime, as many full and hearty meals as I wished, and even in wartime, without starving, by the simple expedient of strictly removing all fat and all carbohydrate from the diet. No vitamins or alkalis are taken. This is a comparatively easy procedure, and still leaves a number of purely protein and cellular foods from which even nowadays quite useful and sometimes hearty meals can be prepared. I have tried it successfully on myself, and although after nearly six years in the R.A.M.C. I cannot aspire to any great interest in a view of male genitalia from whatever angle, I was nevertheless able to record a reduction in weight 85% as good as "Apollonian's" over a comparable period—with the additional satisfaction of being reasonably certain that little or none of this loss was at the expense of my muscles or other body proteins.

Considerably greater reductions were produced in grossly overweight patients, who lost in one case 14 lb. and in another 18 lb. in the first week. I have not yet failed to obtain a minimum loss of 5 lb. weekly in anyone adhering rigidly to this diet, and neither I nor my patients have suffered any ill effects from it.—I am, etc.,

London, N.W.1. A. LEWIS.

Chemically Induced Convulsion Therapy

SIR,—In convulsion therapy drugs have been very largely superseded by the electrical method of inducing the fits. This is because, as Brain and Strauss have pointed out, E.C.T. is inexpensive, simpler, and a relatively safe method. Moreover, it is quicker, easier to perform, and does not spoil the veins. Whereas for many reasons it is desirous to use the electric method of induction, we believe it would be a mistake if the special advantages to be gained by the use of the injections were neglected. In actual fact experience shows that there are differences between electrical and phrenazol fits, as seen by the type of convulsions, the associated changes, and their clinical application.

The phrenazol fit begins with a slight pallor, dilatation of the pupils, and a cough; then the fit sets in with opisthotonos followed by clonus. During the short asphyxial period the eyes are often deviated upwards and the gag is held tightly between the teeth. Then deep breathing starts, the gag is released, and recovery of consciousness occurs. Generally there is an unpleasant memory of the preconvulsive period, with the result that patients frequently dread the treatment. The course of the electrical fit is, however, a shorter one. The onset of the convulsion is instantaneous; it does not start with opisthotonos, but in 70% of a series of our cases with a flexion of both legs at the hips and knee-joints, accompanied infrequently with a flexion of the elevated arms at the elbows, the flexion of both legs going slowly over to an opisthotonos which is then followed by clonus. The asphyxial period lasts longer, the eyes often being deviated sideways, as was observed by Kino, and while consciousness is clouded there are frequently sucking movements of the lips present, even if the gag is artificially removed from the mouth.

The patient has an amnesia for the treatment and consequently the fear is less.

Guttman and Reitman showed that after cardiazol (phrenazol) convulsions the blood pressure rises quickly to above the resting level and returns very slowly. Dax found similar changes with ammonium chloride. In a series of electrical convulsions the same changes were not found, for after the blood pressure became registrable it rose, but not to the same degree as with phrenazol, and it returned more rapidly to the resting level. At first it was thought that the fear and apprehension for phrenazol convulsions played a part in the results, but this was later disproved by Cook. It seems, however, that the general tendency is to emphasize the psychological significance of the *pre*-convulsive "aura" in phrenazol and the *post*-convulsive psychomotor dramatization in E.C.T. Furthermore, in our experience lasting memory disturbances are more marked after E.C.T. than after phrenazol.

Carse and Frank emphasized that patients refusing food showed a better therapeutic response to phrenazol than to E.C.T. In accordance with these observations previous workers had noticed that patients put on weight after chemically induced convulsions, but it was suggested by others that this was the result of the mental improvement. We have also found in accordance with Carse's observations that patients refusing food respond better to phrenazol and gain in weight. In comparison similar cases receiving E.C.T. respond only slowly to the treatment and the ultimate gain of weight averages less than with phrenazol. Based on these experiences, in case of constant food refusal we administer as a routine phrenazol shocks for 3 to 4 consecutive days in preference to E.C.T. We also believe that phrenazol can be used to advantage in cases of stupor, in simple schizophrenics with vasomotor disturbances, and in breaking up a state of mania. Based on these experiences, of a total of 849 patients who received convulsion therapy in 1944 at Netherne, 69 had their convulsions produced by chemical means, the remainder receiving electrically induced fits.

The practical conclusion of these observations and investigations seems to be that while E.C.T. in most cases remains the method of choice for convulsive treatment, chemically induced fits still have a useful field of application. Further clinical research might usefully be directed towards investigating the therapeutic differences rather than the similarities of these methods of treatment.—We are, etc.,

E. CUNNINGHAM DAX.
Netherne Hospital, Couldson, Surrey. F. REITMAN.

Milk Still Unsafe

SIR,—May I be permitted to offer my congratulations on your leading article (Aug. 4, p. 160) under the above heading. The Joint Tuberculosis Council has for many months been making every endeavour to secure some improvement in the present unsatisfactory state of affairs. Resolutions have been forwarded to the Ministry of Health and other interested bodies, attempts have been made to get the medical Members of Parliament to take action; numerous interviews have been arranged, etc., but beyond being told that we were "flogging a willing horse" nothing has been achieved.

The medical profession has a grave responsibility in this matter. Until we so rouse public opinion that Parliament has no option but to pass the necessary legislation we must ourselves accept some share of the responsibility for our 2,000 deaths per annum as the result of bovine tuberculosis. We have the opportunity of stimulating public opinion by impressing upon all our patients the danger of drinking milk which has not been either pasteurized or boiled, and I would suggest that every doctor, whether in private practice or holding a public appointment, should do all he can in this respect.—I am, etc.,

Welwyn. A. P. FORD.

SIR,—I fail to find in your leading article on "Milk Still Unsafe" (Aug. 4, p. 160) any attempt to deal with the matter from a fundamental point of view. As you are aware, 50% of the milking cows give evidence of tuberculosis. You will, I take it, agree that this is the case because the vitality of the cows is so low that their cells are unable to tackle and destroy the tuberculosis in their bodies.

Why is their vitality so low? First, because of wrong food. If the land is not properly fed one cannot expect good grass to grow and contain the lime necessary for giving a satisfactory supply of this mineral. In 1934, in an address to the Carmarthen Chamber of Agriculture, I advocated a Government subsidy to farmers for buying lime, and in a short time this subsidy was forthcoming. Now that the subsidy has been stopped many lime kilns have ceased to function and the land is starved. Secondly, the calves have so bad a start in life that they fail to develop into healthy heifers. The calves are not given their adequate supply of good fresh milk, while those whose mothers give evidence of tuberculosis get milk of an inferior quality and are made all the more liable to fall a prey to tuberculosis. Thirdly, the cows are stimulated to develop abnormally huge udders in order to yield more and more milk, thereby draining them of a vitality which otherwise would keep off the attacks of the tubercle bacillus. Abnormally large udders are in themselves evidence of a departure from good normal health, and the various competitions for high registered averages are as wicked as they are insane.

You write of pasteurized milk as if it were all of the same quality, notwithstanding your reference to the American Army regulation that soldiers must have only pasteurized milk from tuberculin-tested cows. It is well for all your readers to realize fully that pasteurization of milk from Tb cows cannot possibly make that milk an A1 milk even on the first day, while the rapid deterioration of milk which has been pasteurized makes it on the second day of no value at all.—I am, etc.,

Swansea. G. ARBOUR STEPHENS.

⁂ We do not know what an A1 milk is, but we do know that a milk containing tubercle bacilli is rendered safe by pasteurization—witness Price's observations at Toronto. The deterioration in keeping quality of pasteurized milk on the second day is, of course, less than in the same milk untreated; every dairyman knows this. And if by "no value at all" the writer means nutritive value then the statement is simply untrue.—ED., *B.M.J.*

Tuberculous Persons in Prisons

SIR,—The letter of "C.438" (Aug. 18, p. 242) caught my eye and I referred back to the letter of Dr. Audrey Roberts (July 21, p. 100). Does Dr. Roberts not consider she is making libellous statements about a body of well-qualified men and women who devote their lives to improving a somewhat difficult and dissatisfied section of the community—namely, the prison medical service? Does Dr. Roberts know that each large prison carries two or more full-time medical officers, that smaller prisons carry one medical officer (full-time), and that still smaller prisons have medical officers who visit daily?

I retired from the prison medical service after long service in 1939. At my prison we had a number of special cells, facing south, with walls rendered smooth and all angles rounded off, the whole of the walls and ceiling being painted with enamel. They were provided with bedsteads, hard-wood furniture, and chairs with backs; they also had specially large windows and impervious floors. These were for prisoners (tuberculous) who did not require hospital treatment. Prisoners occupying these were employed outdoors all day at light garden work, and were examined once a week and weighed by the medical officer. The more serious cases were treated in bed in hospital rooms with large windows. In my experience tuberculosis is not common among prisoners, and I recollect only three serious cases in 30 years. One was of a man who had been treated in the Isle of Wight and was merely lodged in my prison on his way home to Yorkshire; the journey, unfortunately, proved too much for him. (This was the only patient with tuberculosis who died under my care.) The second was a case of acute pneumonic phthisis; the patient was released in a day or two to a suitable institution, where everything possible was done for him. The third was a case of tuberculous peritonitis, which was operated upon at a general hospital, and a bad prognosis given. The patient was kept on a mattress with suitable protection all the days of a long fine summer; he completely recovered and was last heard of serving a sentence of penal servitude.

Various statements in "C.438's" letter are, I believe, inaccurate—e.g., sanitary conditions are not primitive; there is ample accommodation for attending to the calls of nature in the morning. At the prison where I was, any prisoner who wished to leave his cell to empty any obnoxious matter was allowed to do so up to 10 p.m. on ringing his bell. New entrants should have a new mattress and clean blankets on admission. Prisoners were allowed one hour's exercise, not half an hour. Fruit had not been added to the menu when I left, but the food was good and more than adequate, with such variety as was obtainable (carrots, turnips, and onions were often served).—I am, etc.,

York. F. J. WILFRID SASS.

Weights and Measures

SIR,—The trickle of unsolicited papers and pamphlets describing medicinal and food preparations is already arriving, and may by-and-by become a flood. Before this happens—for we sometimes read them—may I draw attention to the exclusive preference being shown in these to the metric system of measuring dosage, with the ignoring of the Imperial system? In a number of recent instances metric figures alone have been given.

Those of us—and they constitute the great majority—who have been educated in the use chiefly of the English scale continue to believe it good enough and exact enough for all practical purposes; and we feel that English equivalents, which are being quietly dropped, ought to be reinstated as alternatives; indeed, should be given pride of first place. Why prefer the foreign system when we know our own time-honoured English scale of measurements to be reliable and perfectly serviceable in clinical use? The metric system is a recognized laboratory necessity, not to be forced upon the British prescriber or dispenser. In ordering drugs most practitioners adhere to the old English scale, and will continue to do so in spite of much argument against, and in favour of the metric system, which is too fine-drawn for bedside use and only encourages the ready-made to the detriment of prescription writing.

The Imperial scale should be rehabilitated; in default of this being done the waste-paper basket is again likely to find one of its proper uses.—I am, etc.,

Bournemouth. S. WATSON-SMITH.

Doctors and the Social Trend

SIR,—If the people of this country had not opposed the "social trend" in Europe in 1939 we would not enjoy to-day the little freedom we have preserved. Representative bodies of medical men have consistently expressed their conviction that State control of medicine would not be in the interests of the public, medical progress, or the doctors themselves. Shall we now recant against our better judgment because of an election held in an atmosphere of mass hysteria due to reactions after a long war? Many people gave me their reasons for voting Socialist: in most cases it was a blind loyalty to the Labour Party by workers and trade unionists or else a desire for a change at all costs, a result of war-weariness; some for the most illogical and absurd reasons—for example, "Churchill is a war-monger" or "The fat ration is too low." I have, however, yet to meet one person who voted Socialist because he wanted a State medical service. The public are just not interested in it and any agitation for it is purely political.

I know there are a great number of doctors like Dr. Shackleton Bailey (Aug. 18, p. 235) who think a State medical service is bound to come, and for that reason I think we should get down to brass tacks and state the minimum terms that would be acceptable, so that Mr. Bevan may have no illusions. I have gone into this question with various sections of the community, and there is a remarkable unanimity of opinion as to the terms under which a general practitioner of some years' standing might accept State service. Briefly they are: compensation for practice, salary of £1,250 per annum with travelling expenses, pension of £500 at 65, adequate holidays and time for refresher courses. Is the Government in a position to offer us these terms? I very much doubt it. Even if it is, I think we ought still to insist that any doctor who wishes to maintain his freedom and not take part in the service and any patient who wishes to contract out for his treatment should be free to do so without victimization.

The defeatism of Dr. Bailey and many other doctors is quite unwarranted. The medical profession is in an unassailable position, and with a little courage and unity need never be dictated to. Just think for a moment if the miners or the dockers were in our position how they would fight the Government! Besides, we have the heartening example of our colleagues in Australia and New Zealand.

We must expect many attacks now from a section of the Press and the politicians, but when Mr. Aneurin Bevan goes into the matter he will find, as Sir Stafford Cripps did in the case of the cotton industry, it is no easy thing to nationalize medicine. A Bill rushed through the Houses of Parliament could not produce the extra doctors or nurses, nor could it provide additional hospital accommodation—all of which are essential if chaos is to be avoided. I think Mr. Bevan will soon see that the ambitious State medical service which his party has been promoting would require at least ten or fifteen years to materialize, assuming, of course, that our depleted finances can stand it.—I am, etc.,

London, S.E.1. W. B. PEMBERTON.

SIR,—Surely Dr. Shackleton Bailey (Aug. 18, p. 235) as a good Conservative is not going to haul down his colours after one defeat. The fact is that we have a Labour Government for a longer or shorter period of office which is determined to nationalize at least, and possibly socialize, medicine. But Parliaments come and go and cease to have responsibility for that which they have done, but we, as a profession, remain, and do not cease to be responsible for the advice we give to our fellows and our juniors and for the legacy we leave to our successors. That is why a change of Government should not make any change at all in our views as to what is right for our ancient and noble profession.

Doctors are on the whole poor politicians, which seems a good thing, and our decisions are almost entirely free of political considerations and formulated on a fairly clear idea of what is right for our profession and posterity. The latter is the whole crux of the matter. Governments legislate for the immediate future; we must see that that legislation is also the right one for our successors. That responsibility is ours just as certainly as night follows day, and no thinking doctor will deny it. Dr. Shackleton Bailey states that the medical profession can no longer defy a force that has swept Mr. Churchill aside. The answer is that Mr. Churchill has not been swept very far aside, and the medical profession, if united, can defy anything of which it does not approve.

Our leaders realize that in a democracy Governments do not get all their own way. The best results are achieved by the stimulation of a healthy, energetic, and honest opposition.—I am, etc.,

Glasgow. KATE HARROWER.

SIR,—Dr. Shackleton Bailey draws attention to the trend of things with us—in fact the bloodless and silent revolution of our social structure that is being enacted at this very time. Yet, surely, most of us have been alive to these facts for years, and many of us have not ignored them in our various writings from time to time. Nevertheless Dr. Bailey, in common with many others, assumes that General Elections are apt to convey the impression to the innocent that a change of Minister means all is lost and all must be changed. True such a change has brought in new names with doubtless new energy; but it should be kept in mind that it is the workers of all grades who must avert our and their own approaching nudity. If any deluded supporters of the Left remain who imagined that Mr. Attlee when in charge was some form of modern Aladdin who has only to rub his lamp and produce the promised land of milk and honey, clothing, motor cars, and stockings at once, then they have already been warned by Mr. Attlee himself.

Mr. Churchill, "the greatest hero in the hour of his triumph over our enemies," has not been swept aside, as Dr. Bailey most wrongfully suggests. Mr. Churchill's party and policy may be temporarily out of favour as a result of its moderation and precaution in socialistic reforms, preferring to promise something it was sure it could carry out rather than commit itself to a policy of questionable politics. Mr. Churchill's achievements are already part of history. The world speaks justly his high praise, and this needs no further repetition. "The Government may have the votes in the House of Commons, but the Opposition most certainly has the voice. Its voice is that incomparable orator and debater, Winston Churchill."

On the demeanour and manner in which Mr. Aneurin Bevan, ex-miner and now Minister of Health, conducts his affairs in the future will largely depend the continuance or fall of the present Government. Our Minister of Health has uttered few words in his new official capacity, far less outlined his proposed policy for the future of the medical profession, and it does seem unfortunate that Dr. Bailey should choose this juncture to assume the role of prophet, or endeavour to interpret what he thinks Mr. Bevan is likely to propose for the profession, and goes further by suggesting we should accept something before we have even heard the details. It is just possible that Mr. Bevan—not perhaps such a "vehement critic" as he is reputed to be—may yet surprise many of us in his understanding, reasonableness, and soundness of the requests he may place before the profession.

Most of us are aware of the Labour Party's proposals for a *National Service for Health* as published over a year ago (price 2d.) and how only a full-time salaried service would appear to appease that appetite. Yet many of the proposals in this booklet strike notes of common sense, and the doctors, in my opinion, have never desired to oppose the wishes of the public, as Dr. Bailey tends to imply, but in fact have always placed the welfare of the patient in the forefront. They remember that poverty is perhaps still the greatest single cause of ill-health, and that good conditions of work, with full employment and ample opportunity for leisure and exercise, well-built and well-planned homes, plentiful supplies of milk and nourishing food, with sunlight and absence from injurious noises, are much more likely to achieve better health of the nation than good doctoring by itself.

It seems, therefore, essential that those who are entrusted by us to negotiate the future basis of employment of our profession with the elected representatives of the nation should exert all possible influences on the Government of the day to listen to the experience and advice of professional men who have spent their lives studying and advising the sick in their best interests. Our representatives should bear in mind the experience and opinions of those who have served in whole-time salaried medical services such as the Forces (*Journal*, 1944, **1**, 732), and also in the municipal medical services. Already in this country there are "2,000 public hospitals and some 1,000 so-called 'voluntary' hospitals of various types." Examine the numbers of attendances of these two groups throughout the country, and from the result it would appear that an overwhelming majority favour the voluntary hospitals' treatment. Nevertheless, the Government will doubtless ask for, in fact demand, a full-time salaried service, and those who desire it must have it. But let us also legislate for a part-time salaried service, incorporating with it the right of private practice, and so safeguard the interests of the public so that in the event of the full-time service failing (as it has to a large measure in Russia) then we have the alternative part-time National Health Service already in operation to maintain the interests and health of the nation.—I am, etc.,

London, W.1. NORMAN P. HENDERSON.

SIR,—Dr. Bailey's letter should appeal to most members of our profession. There is one point, however, which he might have mentioned. The country and the Government regrettably seem determined to regard the medical profession of the future as a "trade." All trades are protected by their respective trade unions. If we have to consider our profession from the trade point of view with the public represented by the Government as our employer, then our urgent need is for an adequate machinery to prevent our exploitation. This should exist in our British Medical Association.

The vast majority of doctors are not mercenary-minded, but it is quite reasonable for an individual who has perfected himself in a trade which demands high skill to expect both an adequate financial reward and working conditions which enable him to do himself and his patient justice. The Government now in power is reasonably determined to obtain adequate medical attention for every member of the community, but doctors would like to be assured that the means taken to achieve this creditable end are adequate and agreeable not only to the medical man but also to the patient—a process which will take many years to perfect.—I am, etc.,

Eton. JOHN WEBB.

Belsen Camp

SIR,—On my return a few days ago my attention was drawn to a letter from Major F. R. Waldron, R.A.M.C., pointing out certain omissions in my article on Belsen of June 9 (p. 814). I am very glad that he has done so and added the names of the Army units in question, and enlarged upon the work of the Field Hygiene Section of the 11th Armoured Division, who were in the camp before anybody else, when the S.S. were still actually in charge. No praise is too high for them. I am exceedingly sorry that they obtained less than their due. This, however, was not my fault. I was requested to write the article objectively as an observer. I was not in the camp as a worker until later on. I discussed the article with Lieut.-Col. Johnston, the S.M.O., and wrote it partly in his tent. At that time there was a great lack of nursing personnel and Johnston was against handing the people over to German nurses. The article was written with the object of rousing public opinion and getting the release of nurses from home. I asked Johnston to sign the article himself. He did not like to do this, and he did not want any names of individuals or units mentioned, as he felt all had worked so hard that it would be unfair to pick out individuals. An article was then composed and referred to the necessary high command. The latter had already decided on a different policy and hence cut out certain parts of the original article. At the same time they said that the work done by the Army units in the early horror days was so outstanding that they felt these units should be mentioned by name and added the list themselves.

As a matter of detail, it was not stated in my article when the camp was first entered. If Major Waldron looks at the article again he will see that the date April 17 is given by the S.M.O. as the date when *he* first entered the camp and not the date it was first entered.—I am, etc.,

Dublin. W. R. F. COLLIS.

The Training of the General Practitioner

SIR,—I should like heartily to endorse Dr. J. Macleod's letter (July 28, p. 135) on the above subject and also to agree in the main with the suggestions contained in Dr. Frank Gray's article (*Supplement*, May 27, 1944, p. 121). I well remember Dr. Harvey Cushing's remarks in his address to the International Conference in London in 1913, or thereabouts. He then gave it as his opinion that no doctor should be allowed to specialize until he had spent 10 years (I think it was) in general practice (or words to that effect), and I certainly think that that would be a good rule to go by, for the sake of both the public and the profession generally. Otherwise many specialists trained from their youth up in their one line and mostly in hospitals remain narrow in outlook and poor in diagnostic acumen.

Failing such general training a useful substitute would be for specialists to undergo refresher courses in general practice at suitable intervals. Such courses would, I feel sure, broaden their outlook, temper their judgment, and improve their relations with the G.P.s. As Dr. Macleod says, the medical schools are turning out embryo specialists, who, incidentally, seem to consider themselves already in the ranks of the adults and are very apt to "talk down" to the "ignorant G.P." If it could be arranged lectures and ward teaching in medicine and surgery by a good G.P. in every medical school would greatly help in fitting the new graduate for his life's work and getting his mind off rare cases and advanced conditions.

As regards the budding G.P., the young graduate is not only permitted to engage in independent private practice as soon as he is registered but he is also, be he ever so poorly qualified, permitted to purchase the practice of a good G.P., and may be taken on as a presumably worthy successor by a trustful clientele at whose expense he proceeds to learn his job. This is certainly a defect in our present system. Whether he intends to take up general practice or later to become a specialist, it should be obligatory on a young graduate to spend at least two or three years as assistant to an experienced G.P., and on taking up independent practice it should also be obligatory to put his qualifications on his door plate and not be allowed to masquerade as a well-qualified medical man under the simple title "Dr." to which he may not be entitled.

A high-standard diploma in general practice should raise the prestige of the G.P. *vis-à-vis* the specialist. The word "specialist" is exploited *ad nauseam* in professions and trades, and in the public mind suggests a high grade of knowledge and skill and also, unfortunately, a sort of infallibility, all of which are often lacking. It is a pity it cannot be scrapped. With the raising of the standard of general practice which such a diploma might be expected to bring about we should perhaps hear less often such remarks as, "He's only a G.P. of course," and the still more disparaging one, "But then he's only a panel doctor"! Having had some experience of both forms of medical activity I agree with Dr. Macleod in thinking that efficient general practice is of greater value to the public and more difficult to carry out than any specialism, and, incidentally, it should, in my opinion, be able to command at least as high a remuneration.—I am, etc.,

C. H. BARBER,

Thame. Lieut.-Col., I.M.S. (ret.).

Obituary

WILLIAM CRAMER, D.Sc., PH.D., M.R.C.S.

News has reached this country of the death at Denver, Colorado, on Aug. 10 of Dr. William Cramer, who was for 25 years pathologist on the staff of the Imperial Cancer Research Fund and in 1939 crossed the Atlantic to take up the posts of cancer research associate at the Barnard Skin and Cancer Hospital, St. Louis, Missouri, and research associate in the anatomy department of Washington University.

William Cramer was born on June 2, 1878, and received his education at the Universities of Munich, Berlin, and Edinburgh, and at University College Hospital, London. He graduated Ph.D. of Berlin in 1901, D.Sc. of Edinburgh in 1908, and took the English Conjoint qualifications after nine years as lecturer in chemical physiology at Edinburgh University. Before then he had worked for a short time under the Imperial Cancer Research Fund, whose scientific staff he rejoined in 1914. He was elected a Foreign Member of the German Society for the Investigation of Cancer and a member of the Leeuwenhoek Vereeniging. In 1933 he went as official delegate of the British Government to the International Cancer Congress in Madrid, and a year later attended the International Cancer Research conference in Paris as British delegate. At the Skin and Cancer Hospital at St. Louis he was promoted to be head pathologist, and in 1941 gave the Middleton Goldsmith lecture before the New York Pathological Society.

With a wide knowledge of his subject and its literature, Cramer served for some years as sectional editor of the *Cancer Review* and as editor of the *Acta* of the Union Internationale contre le Cancer. He wrote numerous papers published in the reports of the Imperial Cancer Research Fund and in scientific journals on cancer, physiology, biochemistry, and nutrition. His book for students, *Practical Course in Chemical Physiology*, reached a fourth edition in 1920 and his monograph, *Fever, Heat Regulation, Climate, and the Thyroid Adrenal Apparatus*, appeared in 1928. He was a member of the Physiological Society, the Pathological Society of Great Britain, and the Biochemical Society.

By the death on Victory Day of Dr. ALEXANDER BROWN, of Bartholomew Road, N.W., a wide circle has suffered an irreparable loss. He had been a member of the B.M.A. since 1908. He held office as honorary secretary and treasurer of the St. Pancras and Islington Division from 1910 to 1913; was vice-chairman of the Division from 1913 to 1916; chairman in 1916–17; and he represented the Division at the Liverpool Annual Meeting in 1912. Son of Andrew Brown, M.D., he was a King's College man, where in 1894 he gained the Rabbeth Scholarship and the Sambrooke Exhibition. He gained the senior medical scholarship in 1898, in which year he qualified. He practised in the house in which he was born, where the family practice was maintained for nearly 100 years, and he was only persuaded to leave when enemy action had rendered the house a total loss. By good fortune he and his family escaped from the ruins unharmed. He served as a regimental medical officer in France during the 1914–18 war, and often remarked that such is the effect of war on one's contemporaries that he went to the war as "the young doctor" but returned as "the old doctor." Alexander Brown possessed a strong personality with great personal charm—a beloved physician, a true mirror of Oliver Wendell Holmes's lines. As a family doctor he served all classes of his community, and resisted alike the rush of contract practice and the attractions of an exclusive West End clientele. In the difficult sphere of family practice he maintained to a high degree a keen scientific outlook, combined with such a kindly interest in, and consideration for, others as endeared him to all. Quick to perceive the patient's often unexpressed feelings, he easily identified himself with their problems and spared neither time nor effort in their solution. With his accurate observations carefully noted, a consultation with him was both a pleasure and an instruction. It is no faint praise to say that he was in every sense a true family doctor, rich in those qualities which cannot be taught. Medicine owes its stature to the work and example of men like this. While showing selfless devotion in his practice, as a man he shrank from publicity, or even from obtaining his rights if influence were the key. His last illness, in full knowledge of the outcome, was borne with a quiet and characteristic courage. He leaves a wife and two daughters. Many will join them in feeling a very personal loss.—K. H.

Surgeon Commander JOHN DAVIES, who died at his home on Aug. 2 at the early age of 43, was one of the best-known practitioners in Hampstead. He had a distinguished academic record at the Westminster Hospital, qualifying as M.R.C.S., L.R.C.P. in 1924 and taking the degree of M.B., B.S.Lond. in 1928, and the M.D. and M.R.C.P. in 1932. He filled the appointments of house-physician, house-surgeon, and resident medical officer at Westminster Hospital, and that of clinical assistant at the Royal Chest and Royal Ear Hospitals. He settled in practice at Hampstead in 1932 and soon became well known both in medical and in lay circles. He was one of the public vaccinators for the Metropolitan Borough of Hampstead and a member of the Hampstead Rotary Club. He joined the B.M.A. in 1926 and took an active part in the work of the Hampstead Division, being its Representative at the Annual Meeting at Plymouth in 1938 and being appointed chairman in 1939. Soon after the outbreak of war he joined the R.N.V.R., and for two years was posted to the Royal Naval Hospital at Plymouth, where he acted as neuropsychiatric specialist. He was transferred to the Middle East, serving in the same capacity at the 64th General Hospital for two years. There, however, his health deteriorated, and he returned to this country, but continued to serve at the Royal Naval Hospital, Kingseat, Aberdeen, until shortly before his death. The following tribute came from D. B. K. and H. D. L.: In the death of Surg. Cmdr. J. Davies, R.N.V.R., the Royal Naval Medical Service has lost a fine doctor, and we, his shipmates, a beloved colleague and friend. Jackie was a man of boundless energy and drive, which was often the envy of younger and more staid medical officers. Well versed in all branches of medicine, he was chiefly interested in neurology. To this work he brought a sound insight into human nature and a whimsical individual touch. It was while acting as neuropsychiatric specialist in Alexandria that he formulated his famous "Ferdinand" syndrome—applied to those patients in the Forces who, like Disney's bull, did not want to fight but preferred to sit in the fields and pick flowers. But happiest memories of him are apart from work—around the wardroom fire, or in his own charming home—a grand host and a warm-hearted and generous colleague. His many kindnesses were proverbial, but were always performed with so much tact and humour that only those who knew him most closely were aware of the deep and serious strain of compassion in his nature. Jackie never lost the "innocence of anger and surprise" when confronted with a case of injustice, and he would work quietly but fiercely and unsparingly until it was righted. Despite the fact that for months he must have realized the gravity of his illness, he insisted on carrying on until he collapsed. His passing will leave a gap in the hearts of many in the Navy all over the world. To his widow, son, and daughter we extend our deepest sympathy in their great loss.

The following well-known medical men have died abroad: Dr. LUTHER REICHELDERFER, formerly clinical professor of surgery at the Columbia University Medical Department, aged 71; Dr. MARIANO ALURRALDE, ex-professor of clinical neurology at Buenos Aires and ex-president of the Argentine Medical Association, aged 81; Dr. CARLOS BRITO FORESTI, professor of clinical medicine of the Buenos Aires Faculty of Medicine, aged 65; and Dr. MANOEL FRANCISO DE AZEVID jun., formerly president of the Society of Medicine and Surgery of Rio de Janeiro, aged 79.

Medical Notes in Parliament

Dr. Haden Guest has been appointed chairman of the Medical Personnel (Priority) Committee.

A Labour Medical Committee has been formed at the House of Commons with Mr. Somerville Hastings as chairman and Dr. Haden Guest as honorary secretary.

A meeting to discuss the re-establishment of the All-Party Parliamentary Medical Group will probably be held after Parliament has reassembled in October.

New Government and Health Service Proposals

Sir HENRY MORRIS-JONES on Aug. 23 asked the Minister of Health whether he had yet made any arrangements for discussion with the medical profession, the voluntary hospitals, and the local authorities on the Government's proposals for a National Health Service. Mr. BEVAN replied that he had not done so. The Secretary of State for Scotland and he had the whole question at present under review.

Mr. Willink's Statement

During the debate on the Address on Aug. 21 Mr. WILLINK referred to the release of doctors from the Services and hoped that now the war was over the Government would see that the supply of doctors at home was rapidly increased. Turning to the plans for the National Health Service, Mr. Willink said he was disturbed by the statement, made by Mr. Greenwood on Aug. 17, that it was necessary to go back to the position of March, 1944, and to start afresh the discussions contemplated by the White Paper. Mr. Willink said he had always contemplated that legislation should be introduced this year and that the comprehensive health scheme should come into force with or before the general insurance plan. Young doctors, particularly those returning from the Services, should know as soon as possible what forms of professional work were going to be open to them. Planning of hospital resources was urgent, but until there was legislation both voluntary and municipal hospitals would be in difficulty about their future function and development. Mr. Greenwood had made inaccurate and misleading observations about the course of events since March, 1944, and had said that Mr. Willink reopened, behind the backs of everybody else, secret discussions with the British Medical Association. Mr. Greenwood had said the result was a muddle causing great and unnecessary delay. Mr. Willink wondered whether that was put forward as an excuse for delay by the Government. He explained that, at an early date after the Parliamentary debate on the White Paper, discussions expressly contemplated by Parliament had been opened by him and Mr. Johnston. These were not primarily with the British Medical Association. They were with voluntary hospitals, local authorities, and with a body representative of the whole medical profession—the Royal Colleges, the medical officers of health, and the general practitioners. B.M.A. representatives made up about half of one of the three bodies with which Mr. Willink, in conjunction with Mr. Johnston, had discussions. There were other discussions with chemists, dentists, and other bodies. The local authorities much disliked the proposal to transfer their hospitals to Joint Boards.

Mr. BEVAN intervened and warned Mr. Willink that if he was going to tell the House of these negotiations, then Mr. Bevan at some other stage would complete the picture.

Mr. WILLINK said he was in a stronger position to describe what passed than was Mr. Bevan, who had not been present. Mr. Willink reported that both the voluntary hospitals and the medical profession claimed a fuller share in the planning of the future hospital and other services than was accorded in the White Paper. The voluntary hospitals also strongly objected to receiving direct aid from local rates. The best lay and medical opinion agreed that the White Paper scheme gave no adequate place to the influence which universities with medical schools should be able to exert on the planning and development of the hospital and health services. The voluntary hospitals and the doctors were apprehensive about local authority control of their work. The general practitioners were among many who strongly objected to the powers which the White Paper proposed should be entrusted to a Central Medical Board. All these contentions were serious matters proper for discussion. Those who came to discuss them, though critical, were most helpful. In the result by the end of May he and they had reached a stage where, without the loss of a single service contemplated by the White Paper and without a thought of abandoning a wide trial of health centres of various kinds, a structure had emerged likely to command such agreement that it was possible to begin and to make considerable progress with drafting the necessary legislation. There was no muddle whatever. He hoped the Government would not decide that the work and effort given by those most skilled in these matters should be treated as nugatory. There ought not to be an excess of Party politics in the health services of the nation.

Sir HENRY MORRIS-JONES warned the Government that if it ignored the great medical profession and its traditions of freedom they would get resolute opposition, comma by comma, and line by line, from the Opposition side of the House to any National Health Service which obliterated the principle of the private patient having access to his doctor. If the Government intended to make the profession of medicine a State-salaried Civil Service it would be up against the biggest fight it had ever tackled. He was sure he expressed the view of 95% of the medical profession. The conference of the medical profession had, last summer, voted by 93% against some of the proposals which the then Minister of Health brought before them on behalf of the Government.

Mr. HERBERT MORRISON said the Government would go ahead with an effective social security programme. There was more in the social services than feeding the hungry or bringing the doctor to the sick.

Committee on Atomic Energy

Mr. ATTLEE announced on Aug. 21 that to assist them in dealing with the questions raised by the new discoveries respecting atomic energy and its further development in this country for industrial or military purposes the Government had decided to appoint an advisory committee under the chairmanship of Sir John Anderson. On Aug. 23 Mr. Attlee added that research on the possible use of atomic energy would continue to be carried on under the Tube Alloys Directorate of the Department of Scientific and Industrial Research.

Ratio of Doctors to Civilian Population

Mr. BEVAN told Sir John Mellor on Aug. 23 that the average number of civilians per general practitioner in the United Kingdom was 2,576. The corresponding number in relation to medical practitioners of all kinds was 1,359. The number of Army personnel per medical officer in the B.L.A. was about 409, but these officers had considerable additional commitments to displaced persons and others.

Protection of Practices Scheme

Sir E. GRAHAM-LITTLE asked on Aug. 17 whether Mr. Bevan knew that the B.M.A.'s scheme for the protection of absentee practitioners' practices forbade other doctors from attending a demobilized doctor's patients for a period of twelve months after the close of hostilities, "thereby depriving insured persons on his list of their right to a free choice of doctor for that period; and, as this constituted a violation of the National Insurance Act, if he would take remedial action." Mr. BEVAN replied that he was in consultation with the B.M.A. on the subject.

Release of Doctors

Mr. LAWSON said on Aug. 24 that release of doctors from the Army was being accelerated in accordance with the quicker release of the Army as a whole. Delay in the release of categories of specialists would occur owing to the existing shortage and difficulty in finding replacements in these categories.

Medical News

Sir William Douglas has been appointed to succeed Sir John Maude as Permanent Secretary of the Ministry of Health and will take up his new duties in September. He entered the Civil Service in 1914, was assistant secretary and then Secretary of the Department of Health for Scotland in 1935-9, and for the past three years has been Permanent Secretary of the Ministry of Supply. He was created K.B.E. in 1941 and K.C.B. in 1943.

The annual dinner of the Royal Medico-Psychological Association will be held at the Savoy Hotel, London, on Wednesday, Sept. 5, at 7.30 for 8 p.m. Among the speakers will be the new Minister of Health.

Mr. Clifford Morson, F.R.C.S., will deliver a lecture on "The Present Position with Regard to Oestrogens in the Treatment of Cancer" at Whipps Cross Hospital, E., on Friday, Sept. 7, at 8.30 p.m.

Prof. A. C. Chibnall, F.R.S., will give the Procter Memorial Lecture before the International Society of Leather Trades' Chemists in the New Chemistry Building, Leeds University, on Friday, Sept. 21, at 2 p.m. His subject is the contribution of the analytical chemist to the problem of protein structure. Tickets may be had from the acting hon. general secretary, "Craigieburn," Duppas Hill Road, Croydon, Surrey.

The Tuberculosis Educational Institute has arranged a refresher course in tuberculosis for health visitors, almoners, and social workers, to be held from Sept. 27 to 29, at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C. Particulars may be had from Dr. Harley Williams, Tavistock House North. Tavistock Square, W.C.1.

Mr. E. Laming Evans, F.R.C.S., who died on April 6, left estate of the gross value of £53,494. After bequeathing his property to his wife during widowhood he directed that on the death of the survivor of his wife and his sister the ultimate residue of his estate should go to the Royal College of Surgeons of England, the income to be applied for the advancement of and research into orthopaedic surgery, "or should they refuse then to the University of Cambridge for like purposes."

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* infectious diseases were less prevalent than in the previous week: measles notifications went down by 509 cases, scarlet fever by 295, whooping-cough by 136, dysentery by 24, and diphtheria by 14.

The fall in scarlet fever was most marked in the north, Yorks West Riding reporting 53 fewer cases than last week, and Lancashire 50. The incidence of whooping-cough fell sharply in Lancashire, Essex, and Warwickshire, where, respectively, 32, 31, and 31 cases were recorded. The returns for diphtheria for the past three weeks have been 28, 38, and 52 below the lowest return of last year, which was then the lowest level ever recorded. The incidence of measles continued to fall throughout the country, except in Kent, Southampton, Essex, and Norfolk, where it remained practically stationary: these four counties contributed 31% of the total notifications.

The largest returns for dysentery were Lincolnshire 72, Essex 27, London 25, Middlesex 23, Suffolk 22, Oxfordshire 18, Lancashire 17, Glamorganshire 14.

In *Scotland* there was a general fall in the notifications of infectious diseases. Notifications were fewer than last week by the following totals: primary pneumonia 32, scarlet fever 27, measles 24, dysentery 9, diphtheria 8.

In *Eire* notifications of diarrhoea and enteritis, rising by 34, reverted to the high level of July; 54 of the 60 cases were in Dublin C.B.

Scotland's Health during 1944

The report of the Department of Health for Scotland shows a health record that compares favourably with the best pre-war years. The 1944 rates for infant mortality, stillbirths, and maternal mortality, respectively 65.0, 32.5, and 3.0 per thousand, were the lowest ever recorded in Scotland. Diphtheria notifications were high in 1940 with 15,069 confirmed cases and 675 deaths, but each successive year has shown an improvement, although the disease is still relatively prevalent, with 6,835 confirmed cases and 183 deaths in 1944. It is estimated that the incidence during 1944 was 1 in 435 for immunized children, and 1 in 190 for non-immunized children, with case-mortality rates of 1 in 400 and 1 in 18 respectively. The incidence of cerebrospinal fever is falling, confirmed cases during 1940–4 numbering 2,580, 1,868, 973, 641, and 518. During 1944 there were 4,373 cases of dysentery—almost four times the total for 1939. For the first time during the war years the notifications of pulmonary and non-pulmonary tuberculosis fell—there were respectively 7,036 and 2,512 cases. Deaths from pulmonary tuberculosis, 2,978, remained at the level of 1943, and deaths from other forms, 957, were 26 fewer. Notifications of venereal diseases are on the downgrade; the number of cases of syphilis at treatment centres was 3,542, and of gonorrhoea 4,270.

Quarterly Returns for England and Wales

The birth rate during the first quarter of the year was 17.0 per thousand, this being 0.4 below the rate for the March quarter of 1944, but 1.8 above the average of the five first quarters 1939–43. There were 10,656 infant deaths—59 per thousand live births, and 11 below the average for the 10 preceding first quarters. Deaths from diarrhoea of infants under 2 were 5.8 per thousand live births; the rates for the four preceding quarters were 4.9, 4.1, 6.4, and 4.5. The general death rate was 15.1 per thousand, compared with 13.8 for the March quarter of 1944, and 16.0 for the average of the five first quarters prior to 1944.

Week Ending August 18

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 922, whooping-cough 967, diphtheria 351, measles 1,327, acute pneumonia 275, cerebrospinal fever 39, dysentery 259, paratyphoid 4, typhoid 5, poliomyelitis 27.

No. 32

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 11.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week)

---

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Owing to movements of population, birth and death rates for Northern Ireland are still not available.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London.*

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London.*

ANY QUESTIONS?

Persistent Pain after Spinal Analgesia

Q.—*A month after amputation of the left leg under spinal analgesia 18 months ago a patient started to get pain in the region of the anus and perineum—deep-seated, constant when sitting or lying, but not present when standing. She has not got a painful stump. There is no paralysis or area of anaesthesia or hyperaesthesia. Rectal and vaginal examinations reveal nothing abnormal. X-ray examination of sacrum and coccyx is also negative. Injections of proctocaine, both deep and superficial, have made no difference. Is this a sequel of the spinal analgesic, and what further treatment can be given apart from analgesic drugs?*

A.—It is very unlikely that the pain complained of has any relation (save that of time) to the spinal analgesic. Any damage to the conus or to the peripheral sacral nerves would be accompanied either by some weakness of the external sphincter or by some disorder of sensation, and any resulting pain would be unlikely to disappear when the patient stood. It is a fairly good general rule that pains which defy explanation even after the most thorough physical examination, which are unaccompanied by any evidence of organic lesion, and which do not conform to any known clinical type of pain, may be regarded as being of a functional nature and of psychic origin. Such a diagnosis in this case must be provisional and careful, and repeated examinations should be made to ensure that there is no organic lesion developing.

Unless the pain be severe no treatment is necessary; if it be troublesome analgesics may be given, but morphine should be withheld.

Significance of B.S.R.

Q.—*The blood sedimentation rate in this country is usually taken as an index of the extent of activity of an exudative process. It is, however, known that the in-vitro addition of small quantities of globulin to serum greatly accelerates erythrocyte sedimentation, and the highest B.S.R. met with in medicine occurs in multiple myelomatosis—in which condition the serum globulin may reach 8%. In patients with chronic hepato-lienal fibrosis I have found a reduction of the serum albumin with a rise in the globulin fraction. Such cases often have a B.S.R. in the region of 40 mm. in the Westergren scale. Can such a reading be attributed to the changes in the blood proteins? Provided that all other investigations are negative, is it justifiable to ignore the high B.S.R. in such cases, as a sign of an active inflammatory process?*

A.—Measurement of the sedimentation rate of the blood is essentially a refinement of observations on the buffy clot or crusta sanguinis, which go back to the earliest records of medical history. In Fahraeus's classical paper (*Acta med. scand.*, 1921, **55**, 1) there is an interesting account of the many theories and treatments which have been based on the sedimentation rate—for example, the humoral theory of disease and treatment by venesection. It should now be general knowledge that the sedimentation rate is merely a rough index of the colloidal constituents of the plasma in general and of the relative proportion of fibrinogen, globulin, and albumin in particular. A rapid rate of sedimentation is a normal phenomenon in the horse and the pregnant woman. In inflammatory diseases the sedimentation rate is usually raised because of the associated rise in fibrinogen. In chronic hepatic disease it is raised because of the fall in albumin and the rise in globulin. There is no evidence that this is a sign of an active inflammatory process; it merely indicates the inability of the damaged liver to manufacture albumin and the compensatory rise in globulin. Obviously, too, it cannot be ignored, as a progressive rise in sedimentation rate suggests a progressive decline in hepatic efficiency. Owing to the other factors which may affect the sedimentation rate in diseases of the liver—e.g., anaemia, changes in fibrinogen, and possibly changes in the quantity of bile salts in circulation—more accurate knowledge of the course of the disease will be acquired from the actual estimation of the plasma proteins.

In conclusion, measurement of the sedimentation reaction, as of the pulse and the temperature, is a useful criterion of illness, but one should not try to make the test bear more weight than it is designed to carry. There has been a regrettable tendency in recent years to "gild the lily" and to introduce elaborate methods of measuring, correcting, or recording the rate of sedimentation of the red cells which have little justification in theory or practice.

Urticaria and Fresh-water Bathing

Q.—*Since the age of 16 a man now aged 31, otherwise in perfect health, develops a dry eczematous eruption on the inner flexures of the elbows and inner sides of thighs when he starts bathing in fresh water each summer. Exposure to sunlight without bathing does not bring it on, nor does bathing in sea-water. It develops gradually after immersion in fresh water, taking a week or so to attain its maximum, at which it remains until he gives up bathing in the autumn. Baths and showers do not bring it on. He has occasionally noticed what are probably urticarial weals on the same sites immediately on immersion, fading after his bathe. There is no history of urticaria, hay-fever, asthma, or migraine in himself or his family, and no other disease of significance. Can you suggest cause and treatment?*

A.—This very unusual history is not easily explained. The mention of urticarial weals at the eruption sites might point to the form of urticaria caused by exposure to cold, in which a hypothetical dermolysin circulating in the blood stream is fixed to the cells of the skin at low temperature, reacting on warming and liberating histamine, with, in consequence, weal formation. As this would happen in both salt and fresh water it does not fit the facts. The flexural sites of the eruption may suggest an external irritant acting on a sensitive or sensitized skin, and in this connexion it would be interesting to learn whether the immersion in fresh water means in swimming pools where the water is chlorinated. This would seem, so far as the available facts allow, a possible explanation.

Climacteric

Q.—*A woman aged 49 underwent a panhysterectomy for uterine fibroids 3 years ago, and it appears that no ovarian tissue was left behind. Since the operation the patient has become increasingly nervous, having occasional hot flushes, throbbing headaches, and ungovernable fits of temper. Would you indicate a course of endocrine or other therapy which might prove beneficial?*

A.—The facts suggest that the symptoms are the result of the climacteric, and oestrogen therapy should be tried. Give oestrone or one of its esters 0.1 or 0.2 mg. t.d.s. by mouth for two or three weeks. If there is only limited improvement the dose may be cautiously increased, but heavy dosage with synthetic oestrogens or with natural oestrogens by intramuscular injection should be avoided if possible. The object should be to give the smallest dose which will control symptoms rather than relieve them completely. Having determined the amount necessary for this, maintain it for two or three weeks and then gradually reduce the dose, discontinuing treatment completely within 3 months. The principle of gradual oestrogen deprival should be explained to the patient and her co-operation obtained.

If the symptoms are not affected by oestrogen therapy, then a cause other than the climacteric should be looked for.

Achlorhydria and Dental Decay

Q.—*Are transparency and decay of the edges especially of the upper incisor teeth after the age of 60 likely to occur in a hypochlorhydric subject? If so, is it due to the achlorhydria? Or could the taking of a dilute hydrochloric acid at one or two meals a day have any effect as a solvent? Could the condition be due to a vitamin deficiency? The textbooks suggest that the teeth are not subject to decalcification in the later age period.*

A.—There would not appear to be any direct connexion between achlorhydria and dental decay. It is known that workers in chemical plants who have prolonged exposure to acid fumes suffer from decalcification of the more exposed surfaces of the teeth, and decalcification is said to follow prolonged vomiting in some cases. Theoretically the taking of dilute hydrochloric acid could produce the same condition, but would probably have to go on for many years before any clinical signs were evident. It is frequently advised, however, that the acid be taken through a tube or straw, partly to avoid the possibility.

Superficial decalcification as the result of imperfect cleaning is commonly seen in old people, but the teeth tend to become more calcified in old age, the process affecting particularly the dentine.

It is very unlikely that any vitamin deficiency could be held responsible.

Mersalyl and Cardiac Failure

Q.—*A patient has gross oedema due to cardiac failure. The response to intravenous injections of mersalyl is unfortunately becoming less, and the oedema is remaining stationary. I would be glad of advice. Could the mersalyl be combined with mag. sulph.?*

A.—Mersalyl may be given with ammonium chloride. Forty-five grains of the latter should be given in capsules of 15 grains, enteric-coated if possible, 45 minutes before the mersalyl. Intravenous injection of cardophylin (0.25 gramme) might be tried, but is not very likely to surpass the mersalyl. The intake of sodium—mainly, of course, as sodium chloride—should be rigidly controlled. Fluid intake is usually restricted to 1½ to 2 pints. This may cause arterial dehydration, for the bulk of the fluid is in the interstitial tissues. Bacon, meat, and eggs contain a good deal of sodium, and a careful diet should be laid down so that an intake of NaCl of 2 grammes daily is not exceeded. In heart failure there may be hypoproteinaemia, and dropsy may be due to this. Then full protein is needed. Removal of oedema or ascites by puncture may initiate diuresis.

Pyretotherapy for G.P.I.

Q.—*Is there any reason why pyretotherapy in the forms described by Dr. Bartley for gonorrhoea and gonorrhoeal arthritis* (JOURNAL, *Oct. 21, 1944, p. 550, and May 5, 1945, p. 642) should not be used in place of malaria in the treatment of G.P.I.?*

A.—There is no reason why pyretotherapy with T.A.B. vaccine should not be used in the treatment of G.P.I., but it is far less likely to be successful than artificially induced malaria. Many forms of artificially induced hyperpyrexia have been tried in this disease, but none has produced results comparable with those obtained by malarial infection, except those methods which raise the patient's temperature by physical means—e.g., the Kettering hypertherm and similar cabinets. In this connexion it should be stressed that the induction of hyperpyrexia is potentially dangerous, and should be undertaken only by one skilled in the procedure and with optimum nursing and other facilities available.

Treatment of Peptic Ulcer

Q.—*May I have information on the treatment of duodenal ulcer? Do you know of any book which deals with the medical treatment of the peptic ulcers, particularly with post-ulcer diet? All the books murmur vaguely about purées, etc., but none seems to give real practical help.*

A.—The Sippy treatment of peptic ulcer by diet and alkalis is still the standard method. Modifications chiefly concern precautions against avitaminosis and alkalosis and efforts to deal with the nocturnal secretion of acid. The drawbacks of alkalis are compensatory secretion of acid and the production of alkalosis; formation of CO_2 is not a disadvantage. After-secretion of acid is most likely to occur after strong alkalis such as sodium bicarbonate, magnesium oxide or carbonate, and calcium carbonate. These substances are also likely to produce alkalosis if used in excessive dosage. On the other hand, they are cheap and they relieve pain more effectively than the newer alkalis, such as magnesium trisilicate and aluminium hydroxide. The nocturnal secretion of acid can be neutralized by the continuous-drip method, whereby a stomach tube is passed and alkalis, such as aluminium hydroxide gel or a mixture of milk and sodium bicarbonate, are allowed to drip continuously into the stomach throughout the night. Alternatively, the patient may be roused for feeds at 12, 2, and 4 a.m. Aluminium hydroxide has no advantage over magnesium trisilicate, except in the form of aluminium hydroxide gel for continuous intubation.

Evidence of the value of alkalis in the treatment of experimental ulcers in animals is quite convincing. If the gastric juice can be continually neutralized so that the acidity never exceeds *p*H 3.5, pepsin is inactivated and ulcers heal. The difficulty is to maintain this continuous neutrality in the human stomach. Clinical gastro-enterologists have been impressed by the importance of emotional tension in the genesis of ulcer symptoms and the relief secured by rest in bed without alkalis. They therefore tend to be more interested in psychological management and sedation than in the use of alkalis. For similar reasons regularity, frequency, and adequacy of feeds are considered more important than the exact composition of the diet. In fact many diet schedules are inadequate in calories and quite needlessly complicated. Finally, as there are possibly more than a million patients with peptic ulceration in this country at the present time, treatment must be ambulant in the great majority of cases. For all these reasons treatment by diet and alkalis tends to be less strict than in the past. Details of diet will be found in standard textbooks such as Hutchison's *Food and the Principles of Dietetics* or McLester's *Nutrition and Diet in Health and Disease.* The homogenized or strained foods supplied for special diets and infant feeding by the large canning firms are now available again at most chemists' and are useful for purées. Half an hour with an intelligent dietitian will give more help on post-ulcer diets, particularly under wartime conditions, than a much longer time spent in a medical library.

INCOME TAX

Depreciation of Furniture, etc.

J. R. has been informed by the inspector of taxes that depreciation is not an admissible deduction for income-tax purposes, but that he can claim "wear and tear allowance" or "cost of renewals." The inspector suggests that as the cost and date of purchase of each item must be known for the purpose of the wear and tear allowance J. R. may find it preferable to claim renewals.

⁂ The wear and tear allowance is "such deduction . . . as the Commissioners . . . may consider just and reasonable as representing the diminished value by reason of wear and tear during the year." No rule is laid down as to the method of estimating the "diminished value," but the common practice is to start from the cost of the particular asset and write it down by an appropriate percentage year by year. One proviso of the section limits the final allowance in respect of the asset by reference to the amount of its cost less any sum received for it on sale. For that purpose the inspector is entitled to know the amount of the cost of each item on which wear and tear allowance is claimed, even if the Commissioners having jurisdiction in the matter are willing to depart from the normal basis of estimating "value."

Purchase of Practice

M. Y. wishes to buy a practice, obtaining a loan on terms which provide for repayments of principal out of income. Will she have to pay tax on the profits before deducting the amount of the repayment of loan?

⁂ Yes. Such repayments are clearly payments on "capital" account and cannot be deducted in calculating "income." In fact they represent savings in a particular form, and there is no more legal ground for deducting them in calculating income-tax liability than there would be in the case of repayment of a building society loan or even voluntary savings for investment.

LETTERS, NOTES, ETC.

Primary Cancer in Accessory Sinus

Dr. THOMAS LINDSAY, F.R.C.S.Ed., writes from St. Lawrence's L.C.C. Hospital, Caterham, Surrey: Many years ago I reported a case of ? primary carcinoma of the heart. At that time I think it was Duncan Fitzwilliams who asked if the accessory sinuses had been examined, and they had not. The other day a case occurred which at first sight looked like a primary carcinoma of the liver. The liver was very large and riddled with growths. On further investigation the primary growth was found in the maxillary antrum.

Device for Filling Blood Sedimentation Tubes

Capt. M. D. DESHMUKH, R.A.M.C., writes from Harihar: Having read in the *Journal* of May 5 (p. 632) Dr. M. M. Conran's description of a device for filling blood sedimentation tubes I went round to our clinical side-room to show it to the medical officer, Capt. Gian Singh, I.A.M.C., who is in charge of the laboratory investigations. He showed me the method he was following, and it certainly appears to be very much simpler. It is as follows: Attach a well-fitting rubber teat to the upper end of the blood sedimentation tube and fill it like a pipette up to just above the zero mark. Put the lower end lightly on the rubber pad and adjust the level to the zero mark by pressure on the rubber teat, letting out the slight excess of blood; then press the lower end firmly, remove the rubber teat, and fix the clip.

Management and Treatment of Tuberculosis and Venereal Disease

Dr. J. L. WHITWORTH (Melbourne) writes: The report that the Central Hospital, Melbourne, requires several doctors and that this hospital and these doctors are to be engaged on tuberculosis and venereal disease mainly calls for some comment. It will be obvious even to the layman that the concentration of this infective material in the heart of a big city is unwise and unnecessary. That these diseases should be treated "in the great open spaces" should be a foregone conclusion. Further, the expense entailed and the inconvenience caused in trying to manage these diseases under conditions so opposed to the public health would be unreasonable; the aseptic technique would require to be almost fanatical; the risks of infection to doctors and nurses and staff unfair; and the end-results problematical, in spite of the superior skill and attention that would be given, perhaps to the disadvantage and detriment of medical matters elsewhere.

Corrigenda

The last line of Dr. Owen-Flood's letter in the *Journal* of Aug. 18 (p. 241) should refer to "minor epileptics" not "mental epileptics."

By a mishap at the printers the first line in col. 2 immediately under Table V in Capt. Degen's article on "Sequelae of Cerebrospinal Meningitis" last week was transposed to the foot of col 1.

MENINGITIS AFTER SPINAL ANALGESIA

BY

MICHAEL KREMER, M.D., B.Sc., F.R.C.P.
Major, R.A.M.C.

(From a Neurosurgical Unit of the M.E.F.)

The possibility of introducing infection into the subarachnoid space by spinal tap has been recognized from the time that lumbar puncture was first performed, and this possibility must be considerably increased if anything is injected into the theca. Though Babcock (1932), when reviewing the causes of death following spinal analgesia, says meningitis is extremely rare, it is probable that the percentage of infections is higher after this procedure than after any other necessitating lumbar puncture. The literature would appear to support the infrequency claimed by Babcock, for only scattered references can be found, but this may be accounted for by a natural reluctance to report what should be a preventable happening.

Six cases of meningitis after simple lumbar puncture have been described. Siebert (1922), Spiller and Payne (1924), Symonds (1925), and Reynolds and Wilson (1934) gave the details of this group, in which one death occurred.

After spinal analgesia there are more frequent reports. Barrie (1941) describes 11 cases with one death in 96 consecutive spinal analgesias in three months. Livingstone, Wellman, Clark, and Lambros (1943) describe 2 cases which they label " aseptic chemical meningitis," and quote 8 further cases with three deaths from the earlier literature. Evans (1945) gives an account of two deaths from such a meningitis, but does not indicate whether these were the only cases or whether they were the fatalities in a series. The clinical details of all these cases are scanty, and for this reason the group below is reported.

If infection is introduced along a needle track it may obviously lodge anywhere in the course of that track. With lumbar puncture the possible localities are the skin, subcutaneous tissues, vertebrae, epidural space, and subarachnoid space. Each localization gives a fairly typical clinical picture. In this paper are reported seven cases, occurring in the Middle East, of infection of the subarachnoid space after spinal analgesia. One of these patients died, and a post-mortem examination was carried out. Because of its importance in the argument on aetiology and pathogenesis a precisely similar case following diagnostic lumbar puncture is included. The clinical course of this condition is so prolonged that only the first case is given in full detail. The others are briefly summarized. For ease of comparison the C.S.F. findings are collected in the accompanying Table.

Case I : Male aged 22

Jan. 9, 1942.—Herniotomy was performed after the administration of 13 c.cm. of nupercaine. He remained well for seven days and then headache and pyrexia occurred, but it was not until Jan. 29 that he developed clinical meningitis—confirmed by lumbar puncture (Table, L.P.1). Sulphapyridine was given with apparent improvement, but he relapsed very soon. These remissions and relapses continued in spite of treatment, and the patient was transferred to the neurological unit on March 4. He was then fairly well and had a positive Kernig's sign as his only abnormality. On March 18 he relapsed (L.P.5) and was given a course of sulphathiazole. No real improvement occurred (L.P.6), and the next relapse on March 26 was treated with sulphadiazine.

March 29.—Felt very much better. No headache and temperature settled. Neck and back felt easier (L.P.8).

April 1.—He had been very well until the early hours of this morning, when he had a sudden onset of severe renal colic, more marked on the left, with haematuria. The total dosage of sulphadiazine was 100 g., and no more was given. The patient was put on a glucose-saline intravenous drip and given 1 dr. of sodium citrate by mouth every three hours. As no urine was passed between 10 a.m. and 6 p.m., the ureters were catheterized by Lieut.-Col. Ogier Ward. Small clots protruded from the ureteric orifices, and the renal pelves were washed out with bicarbonate solution until the return was clear. After this his urine became normal.

April 3.—He now felt fine and had no complaints apart from slight stiffness in the legs (L.P.9).

May 17.—Until this date he continued to improve apart from residual stiffness in the legs. He developed a headache in the night, and temperature rose to 102° F. On examination no physical signs could be made out—certainly nothing to suggest a recrudescence of meningitis. This settled after two days.

May 25.—Blood count: R.B.C., 4,510,000; Hb, 85%; W.B.C., 10,200, differential normal. B.S.R. (Westergren): Fall in one hour, 48 mm.; in two hours, 81 mm.

The B.S.R. indicated that some active infection was still present, and three days later he again complained of severe pain in the head which was both retro- and supra-orbital. He also had pain in the neck and lower back, going down the backs of both thighs and legs. He had two further relapses, which appeared to respond to sulphadiazine, but by June 16 (L.P.10–13) the lumbar punctures suggested the infection was sealing itself off in the spinal canal. Every now and again apparently a pocket leaked into the general subarachnoid space and there was a recrudescence of the general manifestations. This loculation could be regarded as a stage of lumbar arachnoiditis, and it might account too for the failure to clear completely with sulphadiazine therapy. The drug appeared capable of dealing with the infection when it was generalized in the spinal theca, because this settled more rapidly with than without treatment. The presence of loculation was supported by the poor response to jugular compression and the rise in C.S.F. protein without a corresponding rise in cells. Support for this theory was also given by the symptoms, which were mainly confined to the back and legs and persisted even when the patient was otherwise fairly well. It was decided that the next time lumbar puncture was carried out a simultaneous cisternal puncture should be done and the fluids compared. Any significant difference would indicate that the theory was possibly correct. This was done on June 19 (C.P.14 and L.P.15). Macroscopically the two fluids were very different and, with the laboratory findings, supported the diagnosis of infection confined mainly to the lumbar subarachnoid space with partial blockage of C.S.F. circulation. It was now suggested that, owing to the block, the sulphadiazine did not reach the infected area in reasonable concentration, and it was decided to put a weak solution of the drug into the lumbar theca. The danger of using sulphonamide derivatives by that route was well known, but it was felt that this was due to the great alkalinity of ordinary solutions, and carefully neutralized 1/4% sulphadiazine was used. The *p*H of this was just above 8, and 20 c.cm., containing 50 mg., was injected by lumbar puncture. No untoward reaction occurred.

June 29.—There had been no local or general reaction and the patient felt much better, but could not bend his back with ease and the back of both thighs felt stiff (L.P.16).

July 7.—In the past week the patient had been feeling rather better, but on this day had more local pain in the back. There was no tenderness or redness over the lumbar spines. The legs felt stiffer, but there was no neck stiffness (L.P.17). 20 c.cm. of 1/2% (100 mg.) sulphadiazine solution of *p*H just over 8 was introduced into the lumbar theca No reaction of any kind occurred.

July 13.—The patient had been very well during the past week. He thought his back and legs were less stiff. Again simultaneous cisternal (18) and lumbar (19) punctures were carried out. These indicated that, temporarily at any rate, the local introduction of weak sulphadiazine solution had cut down the infection, though the rise in protein was a little disturbing. There was certainly no clinical evidence of gross damage to the spinal cord, nerves, or membranes. No sulphadiazine was present in either fluid.

July 17.—(L.P.20.) The rise of protein indicated either further obstruction by adhesions in the spinal arachnoid space or a reaction locally to the sulphadiazine.

July 24.—He had a sudden onset of headache and his temperature rose to 101°, but there was no neck stiffness or any increase of leg stiffness (L.P.21). After this he was given sulphadiazine by mouth in a three-day course of 10 g. daily. This was to be repeated each week for four weeks.

Table showing C.S.F. Findings in Case I

	Date	Route	Pressure	Jugular Compression	Appearance	Protein mg./100 c.cm.	Polymorphs per c.mm.	Lymphocytes per c.mm.	Film	Culture
1	29/1/42	L.P.	150	Free rise	Turbid	90	400	1,600	Nil	Sterile
2	5/2/42	L.P.	160	"	Opalescent	80	50	450	"	"

26	14/9/42	L.P.	130	Free rise	"	70	—	20	"	"

L.P.22 and 23 were done on July 31 and Aug. 23. It was disappointing to find the persistence of infection when the four-weeks course had been completed. The possibility of washing out the lumbar theca as described by Symonds (1925) through high and low lumbar or through cisternal and lumbar needles was discussed, but it was decided to postpone this for the present, and to give another intrathecal dose of sulphadiazine at the next lumbar puncture.

Aug. 31.—(L.P.24.) 20 c.cm. 1/2% sulphadiazine (100 mg.) was given intrathecally. Within half an hour there was a reaction, with severe pain in the back which spread up, and in one hour there were severe headache and neck stiffness. The temperature rose to 102° four hours after the injection and there was definite head retraction. Vomiting began about two hours after the injection and continued for ten hours. The patient said that he had not had so severe a headache or pain in the neck or back since the original onset of meningitis. He required 1/4 gr. morphine and 1/100 gr. hyoscine in the night for the relief of pain and headache.

Sept. 1.—The headache, neck stiffness, and backache had now gone and the temperature was normal. Apart from feeling limp, the patient said he was not too bad. Examination showed no physical signs apart from lower back and thigh stiffness. The sulphadiazine solution was investigated, and it was found that the *p*H on this occasion had been tested with a colour indicator which had deteriorated and that the *p*H might actually have been as high as 9. On the previous occasions the *p*H had been determined with the hydrogen electrode. The reaction produced in the patient was therefore due to the alkalinity of the solution, and was a true irritation of the arachnoid giving a meningitic picture.

Oct. 24.—The last two lumbar punctures were done in September, and during the past month the patient had been very well. There had been no pyrexia for six weeks and, apart from a minor bout of furunculosis, no untoward happenings. He walked well, but his legs tired very rapidly. Examination showed no physical signs in any system beyond a limitation of straight-leg raising to 45°. The other systems were normal. B.P., 130/90. Urine: Sp. gr., 1020; no albumin, sugar, or casts present. Blood urea, 32 mg. per 100 c.cm. Blood count: R.B.C., 4,750,000; Hb, 85%; W.B.C., 9,000, with a normal differential. Sedimentation rate (Westergren) normal.

Eight months later this patient was very well apart from stiffness of the lower back and thighs. He still tired very easily. These were his only symptoms and the only signs of damage to the cauda equina.

There can be little doubt that this man had had a lumbar obstruction to the flow of the C.S.F. which cleared spontaneously. It is difficult to see why there had been a completely free period of six weeks after the initial treatment with sulphadiazine. The generalized meningitis had disappeared, either naturally or as a result of treatment, but the recrudescence proves that pocketing had already occurred. The clearing of the spinal obstruction was also seen in later cases. It is probable that in this spontaneous disappearance of adhesions an occasional pocket of infection is liberated into the general subarachnoid space. The continuation of infection in the pockets suggests that the sealed-off areas cannot be reached by chemotherapy. It is possible, however, that these pockets contain sterile pus and that the clinical manifestations are due simply to the liberation of this irritant material into the general subarachnoid space.

Case II: Male aged 25

On Sept. 9, 1942, appendicectomy was carried out under spinal analgesia, 13 c.cm. of light percaine being used. The appendix was acutely inflamed. The patient had a continuous pyrexia after the operation, and three days later complained of some pain in the back, for which no cause was found. It was not until Sept. 21 that there were any clinical signs of meningitis, but the local tenderness prevented any punctures being carried out He was started on sulphadiazine and began to improve, only to relapse exactly as the previous patient had done. He was transferred to the neurological unit on Oct. 3. He then had an obvious clinical meningitis, but was very tender over the lumbar spine. This suggested a possible osteomyelitis of the spine or a spinal epidural abscess. Skiagrams of the spine were negative, and a cisternal puncture confirmed the meningitis The back soon settled and lumbar puncture as low as possible showed a free flow of fluid, thus negativing a large epidural abscess, which would have caused an obstruction. This patient did not respond to sulphadiazine, having many remissions and relapses. Several transfusions were given because the haemoglobin was falling, but with only temporary improvement. By the middle of November his condition had deteriorated greatly; it was obvious that spinal block had developed, and on Nov. 27 intrathecal sulphadiazine accurately buffered was given. This was repeated on three occasions. In spite of the C.S.F. improvement there was no clinical progress, and early in December he had passed into a state of akinetic mutism with definite papilloedema. As in spite of the spinal block the C.S.F. protein remained relatively low it was felt that this block must be very high up. On Dec. 18 the left lateral ventricle was tapped through a burr-hole. Instillation of methylene blue followed by cisternal and lumbar punctures showed that the block was below the cisternal level. In spite of ventricular tapping his condition deteriorated, and on Jan. 8, 1943, as he was moribund, 2,000 units of calcium penicillin were instilled into the ventricle. This produced no clinical change, but his C.S.F. now gave a profuse growth of *Ps. pyocyanea*. He died on Jan. 11.

Post-mortem Examination.—This was carried out by Capt. A. D. Morgan, R.A.M.C. *External appearances:*—The body was that of a pale and extremely emaciated young man. The right pupil was dilated. In the right iliac fossa was a healed surgical wound. *Spine:*—The muscles in the lumbar region were rather juicy, but there was no evidence of extradural abscess or osteomyelitis. The C.S.F. in the lumbar theca was yellow, turbid, and under pressure. The dura mater was slightly thickened and the pia-arachnoid inflamed throughout. Over the thoracic segments of the cord was a thick yellow exudate causing fairly firm adhesions between dura and cord.

In the meshes of these adhesions lay pools of turbid C.S.F. Over the posterior aspect of the lower medulla were numerous small subpial haemorrhages. *Head and contents* :—High in the left parietal bone was an exploratory burr-hole. The dura and its venous sinuses were healthy. The brain surface was dry and the gyri were flattened. A thick fibrino-purulent exudate was observed over the base of the brain; elsewhere the meninges were congested. A moderate degree of internal hydrocephalus was present, the ventricles containing air and a little turbid cerebrospinal fluid, their ependyma being coated with a thick glairy tenacious exudate, most marked in the right lateral and third ventricles. On removing this the ventricular wall showed mottled red foci of inflammation. There was no evidence of abscess formation. *Abdomen*:—The appendix scar was healthy. The liver, spleen, and kidneys were normal in size and appearance; the adrenals somewhat atrophic. The stomach and alimentary tract were normal.

Histology.—Spinal cord :—The grey and white matter appeared normal. The pia-arachnoid immediately surrounding the cord was infiltrated with polymorphs. The nerve roots were surrounded by a similar fibrino-cellular mesh-work. Deep-blue staining, circumscribed patches of concentrated polymorphs, and fibrin indicated cross-sections of elongated strands of fibrino-purulent material which had become inspissated in the larger interstices. Outside this zone the cellular reaction became more lymphocytic, and, further out, a very chronic arachnoiditis was represented by a thick layer of fairly dense, avascular, and relatively acellular fibrous tissue, intimately adherent to the inner aspect of the dura mater. This picture was that of a very chronic infection of the pia-arachnoid membrane, with a peripheral deposition of fibrous tissue. *Brain* :—The ventricles were lined by a thick layer of pus. The vessels just deep to the ependyma showed marked lymphocytic cuffing. The appearances indicated that infection at this level was more recent than in the cord.

This is a most instructive case because the necropsy findings prove what had been suspected on clinical grounds. The patient had had a very chronic, relatively mild inflammation of the subarachnoid space, which had resulted in fibrin deposition with subsequent organization. Some of this may perhaps have been due to the intrathecal sulphadiazine, but there is good clinical evidence that obstruction in the spinal subarachnoid space had begun some four or five weeks earlier. In this process of organization pools of infected C.S.F. had become shut off, and if the unorganized or even organized fibrin should break down then this infected C.S.F. would be liberated into the general subarachnoid circulation. It is possible, too, that these loculi may not develop the same concentration of any therapeutic substances as is present in the free-flowing C.S.F., so that even if the causal organism is sensitive to sulphonamides it is cleared only from the general C.S.F. circulation and not from these loculi. Any dilution of sulphonamide can be obtained, and endless possibilities of rendering a sensitive organism sulphonamide-fast arise. It is impossible to say how these loculi are liberated, but that this does occur can be seen from the relative rapidity with which a spinal block may disappear. This would seem to be a reasonable explanation for the relapses which form the most striking clinical feature of the condition.

Case III: Male aged 27

Herniotomy was performed on Jan. 26, 1942, in a general hospital under spinal percaine analgesia, 13 c.cm. being used. The patient developed clinical meningitis the next day and was treated with sulphapyridine. He improved and relapsed several times and was transferred to the neurosurgical unit on March 4. At first *Ps. pyocyanea* had been found in the C.S.F., but after arrival a short-chain non-haemolytic streptococcus, allied to *Str. faecalis*, and *B. coli* were found. The C.S.F. soon became sterile. Shortly after admission the meningitis increased in severity and he developed papilloedema followed by a right flaccid hemiplegia which became complete. He went on to develop a pseudo-bulbar palsy with increased jaw-jerk and an explosive dysarthria. He did not respond to sulphathiazole in large doses, and on March 23 it was certain that he was developing an obstructive hydrocephalus. He was almost moribund and certainly too ill to stand a posterior fossa decompression. He was started on sulphadiazine. From this time he began to improve and became less drowsy. The sulphadiazine was stopped after 100 g. had been given in seven days. He could now answer questions and respond to commands. The paralysis began to improve, and it became evident that he had a marked cerebellar ataxia on the right. He also had nystagmus on lateral gaze and a cerebellar dysarthria. He continued to improve physically, but as he did so it became obvious that he was badly hit mentally. He complained that he felt in a daze and that his brain worked very slowly. His memory and concentration were very poor, and he could not carry on a conversation for more than a few minutes because he seemed to fall into a dream state. By the time he left for the United Kingdom, at the beginning of June, he was able to walk alone and use his right arm for feeding himself and for writing. I heard from his wife at the end of November, and he had then been invalided from the Service. He was still hazy and unable to concentrate, and, compared with his state before this illness, seemed like a different man. His right arm and leg had almost recovered and he had had no relapse of the meningitis.

This case almost went the way of Case IV, and we were certain that the patient was beginning an obstructive hydrocephalus. It would appear that, whatever infecting organism was present, it was sensitive to sulphadiazine and that the formation of adhesions around the brain-stem did not continue to extend once this compound was given.

Whether the paralysis, which was pyramidal in type, and the cerebellar manifestations, which this paralysis masked, were due to brain-stem adhesions or whether they were due to a toxic vascular accident such as thrombophlebitis is uncertain. In addition to these local happenings there can be no doubt that the higher functions of the whole cerebral mechanism were impaired. The apathetic appearance, the continual complaint of being in a mental haze, and the marked inability to sustain any effort are remarkably reminiscent of the after-effects of a severe closed head injury. No formal intelligence tests were carried out in this case, but ordinary conversation was enough to suggest a falling off from the level indicated by his previous personal history. His wife describes an undoubted change of personality. These are certainly an indication of generalized hemisphere damage. It is unlikely that such damage could be due to the hydrocephalus alone, as this was of relatively short duration. It is more probably a direct result of cortical damage, though whether toxic or directly inflammatory, as has been suggested in meningococcal meningitis (Banks and McCartney, 1942), it is impossible to say.

Case IV: Male aged 24

On Dec. 27, 1941, this patient had a radical cure of a left inguinal hernia performed under spinal analgesia, 12.5 c.cm. of light percaine being used. The next day he developed meningitis. The C.S.F. and ampoules of percaine from the same batch were sterile. He appeared to respond to sulphapyridine, but, as with the other cases in this group, he relapsed frequently. By Jan. 30, 1942, he had developed papilloedema and was transferred to the neurosurgical unit. It was felt that he had an obstructive hydrocephalus, and the right lateral ventricle was tapped and methylene blue instilled. This failed to pass into the cisterna magna, thus demonstrating an internal hydrocephalus. He continued to have acute hydrocephalic attacks, which could be relieved by tapping the ventricles, but this relief was only temporary. On Feb. 20 a right subtemporal decompression was performed and, after this, lumbar puncture gave as much relief as ventricular puncture. This indicated that the hydrocephalus which was still present was no longer internal but external. As daily lumbar punctures did not help, a posterior fossa decompression was performed on March 9 by Major P. B. Ascroft, R.A.M.C. A fistula was made between the cisterna magna and the posterior cervical muscles, and the papilloedema slowly subsided. He improved very slowly. On June 17 an air encephalogram showed considerable dilatation of the ventricles. There was no obstruction at the fourth ventricle foramina, but there was obstruction round the brain-stem—no air passing on to the cortex.

In this case natural cure resulted. In the early stages the patient undoubtedly had a ventriculitis and a blocking of the outflow from the fourth ventricle. By the time this cleared he had developed an obstruction to the passage through the tentorium. He did not respond to any form of chemotherapy.

Case V: Male aged 25

On Dec. 23, 1941, appendicectomy was carried out under spinal analgesia, 12 c.cm. of nupercaine being used. Both the operation and the puncture were uneventful. The appendix was thickened and contained many concretions. Four days later he developed clinical signs of meningitis and was immediately lumbar-punctured. His C.S.F. was sterile at first, but later specimens grew an anaerobic *Staph. aureus*. He had several remissions and relapses, and was transferred to the neurosurgical unit on March 4, 1942. A control period without any form of therapy showed that a remission could occur spontaneously. He made no lasting response to sulphapyridine or sulphathiazole, but after a course of sulphadiazine he improved and no further remissions occurred. He was the only patient in whom no clinical evidence of spinal block occurred during the course of the illness. This lasted for 14 weeks, and a follow-up a year later showed that he had remained free from symptoms. It is impossible to say whether the cure in this case was due to sulphadiazine or to a spontaneous remission. In only one other patient (Case III) did cure follow so dramatically on a first administration of sulphadiazine. In the next three cases it obviously had no permanent effect whatsoever.

Case VI : Male aged 26

This patient had a radical cure of a right inguinal hernia after receiving 12 c.cm. of nupercaine. Two days later he developed clinical meningitis, which was confirmed by lumbar puncture. His fluid grew coliform bacilli and *Ps. pyocyanea*, but soon became sterile. In spite of this and continued chemotherapy with sulphadiazine he continued to relapse for three to four days at a time. During a prolonged remission his sedimentation rate (Westergren) was 39 mm. in one hour. He developed clinical spinal block about two months after the onset, and following this his relapses were characterized by severe pain in the back and a decrease of straight-leg raising with relatively little headache or neck stiffness. He improved slowly and did not relapse again after four months from the onset. His sedimentation rate was now 5 mm. in one hour, and his straight-leg raising 70° on each side.

Case VII : Male aged 19

On Sept. 3, 1942, this patient was operated upon for a low-grade pelvic peritonitis after receiving 13 c.cm. of light percaine. The appendix was involved, but it was thought unlikely that this was the cause. Three days later he developed clinical meningitis, confirmed by lumbar puncture, and a pneumococcus was grown from the fluid. The ampoules of percaine from the same batch as used in this case were sterile, but the local analgesic used for the skin grew *B. coli*. He appeared to respond to chemotherapy with sulphadiazine, but soon relapsed, and he continued relapsing and improving for five months before the infection fully cleared up. Like the preceding case, he developed spinal block about two months after the onset, and this disappeared slowly as the condition improved.

Case VIII : Male aged 29

In this patient the meningitis followed lumbar puncture. He is included because the course of the disease was precisely similar to that in the previous cases though no foreign substance had been injected into the subarachnoid space. In July, 1942, he had a pyrexial illness, in the course of which a lumbar puncture was performed. C.S.F. was perfectly normal. As his symptoms continued he was lumbar-punctured again, and on this occasion the puncture was reported as being difficult and a heavily blood-stained fluid was obtained. Six days after this second puncture he developed meningitis, which was confirmed by lumbar puncture. No organisms were grown. He was transferred to the neurosurgical unit and found not to respond to chemotherapy. He developed spinal block in five weeks, and lumbar punctures were given up. He did not improve, and five months later he was given calcium penicillin 2,000 units by lumbar tap. Unfortunately this was from the same infected batch as used in Case II, and there was a recrudescence of symptoms with a frank *Ps. pyocyanea* infection. This slowly cleared, and a month later he was almost cured. No further relapses occurred after this. The spinal block diminished as the condition improved. Until infected with *Ps. pyocyanea* in Jan., 1943, the case had differed in no essential feature from the previous three recorded. This case is of great importance, for it demonstrates that such a meningitis can occur without the deliberate injection of a foreign substance and cannot be due to chemical irritation alone.

These cases are similar enough to be considered as one group. The condition is a low-grade meningitis which, if it is not stamped out almost at once, causes the deposition of fibrin and the formation of adhesions, in the meshes of which infected C.S.F. may remain for a long time. Periodically this infected C.S.F. may be liberated into the general subarachnoid space and so cause a relapse. This illness is not as a rule immediately serious because the infecting organisms are rarely of high pathogenicity and, unlike the pyococcal infections, life is not at once threatened. So long as the condition is confined mainly to the spinal canal the arachnoiditis, whether it produces spinal obstruction or not, can cause no serious complications and, given time, will eventually resolve. When the infection spreads into the cranium, then adhesions may cause an obstruction to the flow of C.S.F. through either the fourth ventricular foramina or the tentorial hiatus. This results in hydrocephalus with its characteristic signs and symptoms. A ventriculitis may occur, but the general symptomatology and the post-mortem findings suggest that it is rare and if it occurs is late.

At some stage during the course of the illness the stiffness of the back becomes and remains more pronounced than the neck stiffness. This back rigidity usually continues for some time after the infection has died out and recovery is apparently well established. It is probable that the stiffness is due to spinal-root irritation. In the necropsy on Case II it was seen that the nerve roots were surrounded by a fibrino-polymorph cuff, and it is probable that until this undergoes resolution the irritation and consequent stiffness are maintained.

Aetiology

Three possible explanations have been advanced to account for the production of this form of meningitis.

1. The Chemical Theory

This theory suggests that the condition is entirely due to the irritant action of the spinal analgesic and that infection plays no part. This explanation is used by Livingstone, Wellman, Clark, and Lambros (1943) for two cases occurring in 4,006 nupercaine instillations. The clinical picture they describe is that of a mild meningitis occurring after special aseptic precautions which, on paper, seem almost fool-proof. The meningitis lasted four and five days respectively and then cleared up completely. No relapses occurred. The cellular outflow was almost entirely lymphocytic, with a rise in protein content in a sterile C.S.F. It is possible that these two cases may have been chemical in origin. There can be no doubt that the spinal analgesics are irritants and, like all irritants put into the theca, produce a protective reaction.

There have been several investigations into the changes in the C.S.F. following analgesia. Barker (1909) found that 24 hours after intrathecal stovaine there was an increase in leucocytes of various kinds. Iason, Lederer, and Steiner (1930), 12 hours after novocain spinal analgesia, found a pleocytosis, mainly lymphocytic, in 14 out of 31 cases. There was an increase of sugar but not of protein, and no correlation was observed between C.S.F. changes and post-spinal reactions. Konwaler (1943) investigated a series of patients one, two, and three weeks after spinal analgesia and found no changes of any kind. Experimental work has been done by Davis, Haven, Givens, and Emmett (1931). After the intrathecal injection of nupercaine in dogs, admittedly in larger doses weight for weight than are used in man, meningitic changes were present in the arachnoid. These consisted of a thickening of the membrane and collections of proliferated arachnoid cells and plasma cells in the interstices of the membrane. The exudates were mainly lymphocytic. If the animals were killed later, then organization and scarring was seen. This was most marked in the lumbar and sacral region and diminished steadily up the cord. There were some inflammatory changes in the ganglion cells and axis cylinders, but these were less definite and seemed less permanent.

There is therefore good evidence of the irritant effects of the spinal analgesics, but it would appear that with ordinary clinical dosage this irritation comes on at once, is short-lived, and settles down without relapse as the irritant is got rid of. A very good illustration of this occurred in Case I when sulphadiazine solution of too alkaline a reaction was put into the C.S.F. There was an immediate accentuation of meningitis, beginning in the lumbo-sacral region and travelling up the spine to the head accompanied by an increasing pyrexia. The reaction, though violent, lasted less than 24 hours, and there was certainly no tendency to relapse, as this was the beginning of complete recovery from the existing relapsing meningitis. Similar chemical "meningitis" has been seen after the use of impure or deteriorated iodized oils for opaque myelography. This clinical picture is quite different from that occurring in true infective meningitis.

The infrequency with which the infecting organism has been isolated is used to support the chemical theory, but, as has been shown by Smith and Smith (1941), it may have no significance. This is discussed more fully later. This theory cannot explain meningitis which follows simple lumbar puncture, as in Case VIII of this series and the similar cases quoted from the literature, for in these no irritants had been put into the theca. Yet the natural history of this meningitis is identical with that following the spinals. This would suggest that, whatever part the irritant may play, it is not the direct cause of the condition. It is also difficult to see why only one ampoule of a batch of percaine should be irritant.

2. Secondary Meningitis Theory

The next possibility is that the meningitis is secondary to infection elsewhere in the body. Weed, Wegeforth, Ayer, and Felton (1920) suggested on experimental grounds that lumbar puncture in the presence of bacteriaemia may produce meningitis, and their findings were confirmed by Remson (1936). This work is open to criticism because a heavy bacteriaemia was necessary before positive results were obtained. Pray (1941), from an analysis of pneumococcal meningitis in children on whom lumbar puncture had been performed before the onset of the meningitis, was not able to confirm the experimental results.

In the present series, Cases I, III, IV, and VI were "clean" hernia operations, and there was no reason to suspect the prior existence of a bacteriaemia. In Case V a subacute mildly involved appendix was removed, in Case II an acute appendix was removed, and in Case VII a low-grade obscure peritonitis was found. In none of these patients was there a suggestion of bacteriaemia in the pre-operative phase. The clinical features of all the cases recorded were so similar as to suggest the same aetiology and pathogenesis in all. As secondary meningitis is not possible in the "clean" cases, one may argue that it is an unlikely explanation in the others.

3. Infective Theory

The third possibility is that the meningitis is due to the introduction of infected material along the lumbar puncture needle. It is true that in a number of cases it has not been possible to isolate the organism as might be expected in an infective condition. This may have a variety of explanations. In five of the cases described above the C.S.F. was sterile throughout the course of the disease if the known contamination with infected penicillin be excepted. In the three cases in which an organism was found it very soon became so attenuated that it could no longer be cultured. In spite of this the clinical state did not improve, thus indicating that the infection was still alive. If attenuation is the cause of the failure to isolate an organism then it may be that in the cases in which the C.S.F. was sterile from the first this attenuation was present early. Whatever the cause the only point that is made here is that failure to cultivate an organism is compatible with an infective origin. This is not infrequently seen in the meningitis which follows open wounds of the brain—an infective condition by all other standards. Smith and Smith (1941) have shown that special techniques are necessary to cultivate the organisms which may be found in this type of case, thus explaining some of the failures.

In the cases described by Barrie (1941) no causal organisms were found. The clinical picture and the necropsy findings, however, suggested an infective cause. Because of this negative bacteriology it was suggested that the condition was due to a virus, though the C.S.F. findings were unlike any meningitic reaction to known virus diseases. This carries the significance of the "sterile" C.S.F. too far. If an epidural abscess, osteomyelitis, or a subcutaneous abscess follows a lumbar puncture, it is regarded as infective whatever the bacteriology of the purulent material, and there is no logical reason why this should not be extended to the subarachnoid space.

The delay which usually occurs between the operation and the onset of meningitis is very suggestive of a phase of multiplication of an organism as a preliminary to the phase of clinical activity. The cases described all occurred in small groups—three in one hospital and two in each of two other hospitals. This may indicate that the conditions necessary for infection to take place were present in one institution for a short time and then were no longer found. Probably the most convincing evidence in favour of the infective theory is the cessation of fresh cases with the tightening up of aseptic technique.

4. Mode of Infection

From the evidence presented it is reasonable to conclude that these cases of meningitis are due to the introduction of organisms into the C.S.F. There can be little doubt that the spinal analgesics are mild irritants, and it is possible that the reaction to this irritation with the outpouring of protein-rich fluid gives reasonable conditions for an organism to gain a foothold. In no case has the spinal analgesic itself been infected. Bacteria have been found, however, in every other fluid used during the lumbar puncture. These include the local analgesic used for anaesthetizing the skin at the site of puncture, the spirit used for sterilizing needles and syringes, and the water used for rinsing these needles and syringes. There is no need to give here the details of the asepsis necessary for lumbar puncture and spinal analgesia, as every aspect has been fully considered in papers by Carnegie Dickson (1944), and Evans (1945), and in the *Lancet* (1944). That there is need for an absolutely rigid technique is shown by Smith and Smith (1941), who found bacterial contamination in 89 of 223 specimens of C.S.F. It is true that the contaminants were mainly non-pathogenic, but they suggest that these might be activated under suitable conditions. They thought that the contamination was mainly due to the "sterile" water used for rinsing needles and syringes, but it is possible that the sterilization of needles and syringes by means other than dry heat may be faulty.

Treatment

The only satisfactory treatment is prophylaxis. It should be possible to avoid these unhappy cases completely. If, owing to an emergency, a rigid technique is not possible, then spinal analgesics should not be used.

If the condition does occur it is essential to stamp out the infection as soon as possible, otherwise it may go on for months and even prove fatal. Unfortunately the causal organism is often not susceptible to present-day chemotherapy—i.e., sulphonamides and penicillin—but this should not prevent these substances being given an early and adequate trial. Once it has been established that they are ineffective, not only in preventing relapses but in clearing up each relapse, they should be discontinued. The commonest infecting organisms are probably *Ps. pyocyanea* and atypical *B. coli.* Botterell and Magner (1945) have suggested intravenous iodides for the former, whereas Ecker (1945) has found a combination of urea and sulphadiazine useful for the latter.

The formation of adhesions causing spinal block is common and calls for no special treatment, but if hydrocephalus occurs, then surgical relief may be necessary. In none of our cases was an attempt made to wash through the spinal subarachnoid space as suggested by Symonds (1925). In retrospect it appears that this may be a useful manœuvre if not put off for too long, as it might break up strands of fibrin and so wash away the foci of infection which cause relapses later on.

Apart from the specific attack on the meningitis all measures used in a long-continued septic illness must be tried, and of these whole-blood transfusion would appear most valuable.

Summary

Seven cases of meningitis following spinal analgesia and one following diagnostic lumbar puncture are described.

The condition is a low-grade meningitis caused by a variety of organisms introduced at the time of lumbar puncture.

The main clinical features are the chronic nature of the illness and the tendency to relapse.

It is suggested that this is due to the formation of adhesions containing infected C.S.F., which is liberated from time to time.

These adhesions may cause spinal block or hydrocephalus.

The cause of the condition is discussed, and on the evidence available it is decided that the likeliest cause is infection due to faulty aseptic technique. The irritation produced by the analgesic may enable an organism to gain a foothold.

Treatment is mainly prophylactic.

My grateful thanks are due to Brig. D. McAlpine, then Consulting Neurologist, M.E.F., for placing these patients under my care and for his constant help and advice during the many anxious moments of their long-continued illnesses. I must also thank Major R. W. Cope, R.A.M.C., for his advice in all matters relating to spinal analgesia, and Lieut.-Col. G. H. Buttle, R.A.M.C., for help in all matters relating to chemotherapy and the *p*H of solutions. Col. H. D. F. Brand very kindly permitted me the use of the hospital records.

TREATMENT OF BURNS: A PLEA FOR SIMPLICITY

BY

C. W. FLEMMING, O.B.E., M.Ch., F.R.C.S.

Air Commodore; Consultant in Surgery, R.A.F.; Surgeon, University College Hospital

> "It can be said truthfully that the treatment of burns has returned to chaos."—Major-General P. H. Mitchiner.

It is sad to think that a distinguished surgeon and respected critic should be forced to the conclusion quoted as a text at the head of this paper. Modern war causes many burns, and during the past five years more surgeons have had to treat these cases than at any time before, and yet it must be agreed that about the treatment a good deal of confusion still exists. In part, at least, this confusion results from the large number of articles published and the numerous memoranda issued by separate authorities. Anyone who adds to this spate of literature takes upon himself a grave responsibility lest he confound yet more deeply the struggler in this therapeutic tangle. Yet General Mitchiner's challenge should be accepted.

My approach is purely clinical and personal. What follows is based on the results of treating regularly during the past five years patients with burns, under conditions that have varied very considerably. The numbers have not been vast, but the intake of patients has been very constant. Much has been learned from surgeons, physicians, pathologists, sisters, and orderlies. I do not intend to refer widely to the writings of others, believing that a picture drawn from the experience of one individual may be clearer than one which is composite.

Origin of the Chaos

The first step in trying to clear the confusion is to analyse some of its causes. A burn is a wound with infinite possible variations. It may extend widely or deeply, or both. Its effects vary according to the general condition of the patient—his age, his fatigue before being hurt, his associated injuries. Treatment depends on factors imposed by time and space: Was the patient burned in a factory, a tank, or a ship? Did his aircraft crash close to a well-equipped hospital or on a temporary landing-strip in the desert or jungle? The list of changeable factors in any single case of burns could be extended, but enough have been quoted to show that each patient must be considered individually. Yet surgeons hanker after a universal panacea. It is not uncommon to be asked, "How are you treating burns now?" That question is as intelligent as "How are you treating fractures now?" The questioner should not really be blamed for the folly of his remark, because from his student days onward he has been led to believe that there is "a" treatment for burns. Even the authors of the admirable Field Surgery Pocket Book published by the War Office in 1944 write that "there is *to date* no cure-all for burns," being reluctant to abandon the hope of some magic still to be found. Twenty years ago all burns were treated with carron oil or picric acid. Later, tanning was introduced, and this notable advance fell into disrepute because it was employed in all burns in all places under any circumstances. Unfortunately its defects were not critically analysed: its whole use was condemned, to be replaced by another panacea—the dyes. The saline bath, envelope irrigation, and plaster-of-Paris came next, and again were judged on their universal applicability, and by this uncritical test were found wanting. The same fate probably awaits penicillin.

The treatment of burns must in the present state of knowledge be to some extent empirical, because the pathological processes which make the patient ill or cause his death are as yet not fully understood. But by careful observation of those signs and symptoms which are comprehensible a high standard of treatment can be achieved, function can be preserved, and lives saved. Such a study can perhaps be more easily made in the Royal Air Force. The admissions for burns are steady and regular, and there is only very rarely the urgent pressure of a large number of battle casualties. Furthermore, the nature of the trauma and the extent of the burns which follow an aircraft crash are remarkably constant, so that successive cases are comparable. The extent of such burns depends on the protection of clothes, and from the same trauma a man is more seriously injured if wearing a sleeveless shirt and shorts instead of full flying clothing. A study of these two groups of cases—those at home and those over-seas—has been clinically instructive. From that study has emerged a plan of treatment which, with variations, can be made applicable to any case of burns; but at each stage of treatment the surgeon must examine his patient, and the details depend on the circumstances of the time and his own experience. There is no single all-embracing universally applicable treatment for burns, and never will be. The surgeon who attains that belief is a long way towards reducing chaos to order.

Degrees of Burns

From the clinician's point of view burns are of two degrees—slight and severe. Slight burns are those in which there is no detectable general disturbance; severe burns are those in which the general treatment of the patient is more urgent than the local treatment of the burn. The differential diagnosis is not always so easy as it sounds, because fit young men widely burned show for a few hours an astonishing vitality. One such walked four miles to get help for his injured companions. This temporary well-being leads at times to disaster, for it is followed by a quite sudden collapse. Patients apparently not very ill have been sent by ambulance car or aircraft on journeys they were not fit to make, and have arrived at hospital moribund. If there is any question in the medical officer's mind as to whether the case is one of severe or slight burns the patient must have the benefit of the doubt. No patient has died because his doctor took an over-cautious view of his burns and refrained from rushing him off to a special centre; a number have died because they were thought to be fitter than they in truth were.

Any other classification, or attempt at classification, in the early stages is useless, and (what is worse) confusing.

Slight Burns: Local Treatment

There are three types of local dressings available: (1) wet dressings, changed at intervals, of saline or antiseptic; (2) occlusive dressings, of tannic acid or dyes; (3) greasy dressings. A wet dressing is suitable for a fresh burn not cleaned or an old one gone septic. An occlusive dressing is successful if the wound is clean and the burned area one that is relatively immobile. It is therefore not good as a first-aid dressing, nor on the fingers, face, and flexures. Greasy dressings are very comfortable and proper on the face and fingers, but should not be used too continuously; the raw surface gets grease-logged and indolent. It is admirable as the skin heals. All three have their place in the local treatment of burns if the surgeon knows why he has chosen one of the three for the particular problem he is trying to solve.

Since the appearance of considerable numbers of cases of sulphonamide skin sensitivity, the use of any sulphonamide powder locally is to be viewed with some caution. For first-aid treatment wet saline dressings give reasonable comfort and do not prejudice later treatment; "Glasgow cream," if available, is probably best of all. Penicillin is still experimental. It seems so far to have a place but not a monopoly in the local treatment of burns.

Severe Burns: General and Local Treatment

In every case of severe burns there are a series of symptoms and signs which must be looked for, and, if found, treated. The details of treatment vary, but the particular points should be checked over in each patient.

1. Any case assessed as severe first requires intravenous plasma. It is extremely valuable to have the haemoglobin estimated before treatment is started, and essential to have this done as soon as possible: from beginning to end, the chart of the haemoglobin percentage is as important as that of the temperature and pulse. Follow the plasma by intravenous glucose-saline until it is apparent that the patient can drink enough, without vomiting, to prevent dehydration. A fluid-intake-and-output chart gives the surgeon complete information on this point, and treatment varies accordingly. There obviously cannot be a statutory number of bottles or days during which the drip should be maintained.

2. Local Treatment.—Despite the early appearance of organisms in a burned area there is no desperate rush to get at the wound. Under morphine alone, the burned areas are cleaned with all aseptic rites, blisters snipped, and very carefully dressed with tulle gras or

vaselined gauze or Glasgow cream. If possible, these dressings are to stay on several days; the most likely reason for having to shift them is that they become uncomfortable. Hence the need for care in applying them. Guard the ends of the fingers by a Cramer wire splint which projects beyond the tips. Give morphine for pain. The procedure is slow: to be done properly it must be done carefully. Under the urgent pressure of battle it may be very difficult to do properly, but that is no real criticism of the method. There are surgical operations which cannot be skimped or done roughly without the work becoming second-rate: the first dressing of a burn is one of them.

3. It is, as already stated, the purpose to leave the dressings alone for four days at least. In the interval the patient needs fluids, glucose, and rest. If his burns are reasonably comfortable he will sleep better with a hypnotic than with morphine. So many doctors seem to have no thought beyond morphine, though the man is suffering not so much from pain as from sleeplessness and nightmares.

4. After three to seven days, depending on the general condition, it is time to think of doing the first dressing. The limbs are beginning to get uncomfortable; the patient is rested; his fluid intake, by whatever route, stable. For an extensively burned patient there is nothing which makes him so comfortable, or the dressing so easy, as a bath. Elaborate machinery, though desirable, is not essential. An ordinary bath, cleaned with cresol, filled with warm water to which salt has been added to give rough normal salinity, does very well. On one occasion a bath filled with buckets of water boiled on primus stoves met an urgent need in treating two badly burned airmen. In the early stages, during the separation of sloughs, a daily bath seems best. Later, when the wound reaches the healing stage, it may make the granulations soggy. Judge the need for baths by the state of the wounds and the comfort of the patient. If the hands are burned, keep the fingers moving in the bath. For limited burns, especially of the hands, the envelope irrigation treatment is successful. With adequate organization, baths are as easy to arrange: with a large number of cases to be treated and a small staff, envelope irrigation may be a satisfactory alternative. But I feel bound to point out that some form of bath treatment centre can be improvised in any hospital if it is thought important enough: in R.A.F. hospitals in one command abroad a bath department was planned in each improvised building as automatically as was the operating theatre.

5. Food, with extra proteins, is the next care. In practical terms this meant abroad plenty of eggs. Patients with badly burned faces are apt to go short, but an adequate diet is very important. As important is attention to the bowels: these patients get constipated, and are much more comfortable and eat better when their bowels start to move.

6. Check the haemoglobin at any time that the patient's condition causes anxiety or if progress is slow, and always on the tenth day. If it is below 80%, check daily, and if thereafter it falls two days running, give a pint of blood. Give more if this does not check the fall, but one transfusion sometimes starts the curve upwards.

7. As the patient's general condition improves, the question of first-aid grafting where skin has been destroyed becomes urgent. The aim of the general surgeon is to preserve function and give the plastic surgeon as good a foundation to work on as possible. Ogilvie's definition of the need at this stage for " more optimism than sense " is the guide. It is often practicable to get skin to " take " on a raw area on the back of the hand that is continuous with discharging areas over infected phalanges. It is beyond the scope of this paper to discuss details of grafting, but it is important to know when to start this procedure. The answer is—at the very first sign of spontaneous healing at the edge of the raw areas. Whatever the bacteriology of the wound may be, natural healing shows that conditions are favourable for trying to graft. If the first attempt fails, try again. Thiersch, " postage stamp," and pinch grafts all have their place.

Summary of Important Points

It has already been explained that there can be no universal treatment for burns, but the purpose of this contribution is to try to show that there are certain recurring clinical pegs on which to hang the details of treatment.

1. Decide whether the burn is slight or severe. If in doubt, treat as severe and give general treatment first.
2. Local treatment depends on the nature of the wound and a consideration of outside factors such as nursing and transport.
3. Prevent dehydration by checking fluid intake and output. Ensure sleep.
4. Baths.
5. Watch the diet. Keep the bowels open.
6. Watch the haemoglobin and keep the record on a chart.
7. Graft at the first prospect of success.

By going over these points when faced with a case an intelligent approach to treatment is achieved. It used to be so common to find the surgeon wondering what to " put on " a dirty-looking burn ten days old when the patient had been constipated for a week and had a haemoglobin of 50%. Whether or not sulphonamides, penicillin, or anything else should be used can all be decided by observation of the individual patient, his wounds, and his charts. They cannot be given by rule of thumb.

Shock and Toxaemia

These two words appear in any paper or discussion on burns, and this one is no exception. They are, however, introduced for a special reason. Until they receive a much more definite meaning the surgeon treating burns would do well to forget them. That is not to deny that they are pathological factors, and it is to be hoped and expected that pathological and biochemical research will endow them with meaning which will aid the clinician in specific therapy. Until that day arrives the surgeon should break down his patients' symptoms and signs into words which have a practical application—pain, sleeplessness, dehydration, anaemia, and so forth. He will find it more profitable than sheltering behind " shock " and " toxaemia," which delude him into thinking he has made a diagnosis, and leave him stranded as to what to do to help. In certain severe cases he will find that there remains, when all possible lines of treatment have been used, some unknown factor which is keeping the patient ill and preventing progress, and for convenience that something unknown can be called " toxaemia." It is, however, for the clinician a dangerously seductive word, and there is a good case for using it very cautiously and a better one for not using it at all.

Comment

The infinite variety of problems presented for solution in the treatment of burns means inevitably that a volume of great size would be required to cover all the points that can arise. The omissions in this paper are deliberate. The points stressed are of universal application, and on them can be based the details which must be considered in every case. One omission demands a note—namely, the value of blood-pressure estimations. In so many of my patients has it been impossible from the nature of the burned areas to obtain readings that I have ceased to rely on them, depending on other signs for guidance: but if the blood pressure can be measured it helps.

On one point of detail a personal view is submitted. Severely burned patients travel badly until their general condition is stabilized, which usually takes from four to ten days. Long journeys for injured patients form a tragic feature of surgery in an oversea command. Burned patients do better if their general condition is treated well and they are kept quiet and still even under quite rough conditions, with poor facilities for local treatment, than if they are hurried away to the most lavishly equipped special centre. Paradoxically, some of the most severely burned men have lived because the medical officer forward has had no doubt in his mind that a journey would be fatal, and has kept and treated his patient, while others less badly injured have been sent on their way and have died. Hence the urgency of the need for teaching that in any case of doubt general treatment must have priority, and for eradicating the belief that there is some local dressing, be it ointment, powder, dye, or lotion, which can by its wonderful property save the patient's life.

Conclusions

In our knowledge of the treatment of burns there are gaps. They will be filled by the researches of pathologists, biochemists, and others; and with the information they provide the surgeon will be able to approach his patients with more confidence than he now has. My failure to refer to the amount of work done on this subject implies no disparagement, but its very mass is to the clinician somewhat confusing. It is my contention that the surgeon who tackles a case of burns as he would any other traumatic problem, with an analysis of symptoms and signs, will find his anxieties enormously reduced, his path clear, and in his mind tidiness instead of confusion. He will find himself varying his detailed technique from case to case as in any other branch of surgery. As research develops new information he can try new lines, for with their variety burns keep on presenting new difficulties for solution. But withal he must avoid the confusion of detail and not be ashamed to rely on the simple practice of good surgery.

I am very grateful to many medical officers serving on units and in hospitals and in administrative posts, to nursing sisters, and to orderlies. They have shown that the handicaps imposed by an oversea campaign, the necessary improvisations, and long-distances are no real bar to a high standard of burns treatment when faced with intelligent enthusiasm and understanding. For such views as are not in accordance with the current teaching on burns, or appear unduly dogmatic or provocative, I am solely responsible.

FIRST-AID TREATMENT OF PHOSPHORUS BURNS

BY

W. McCARTAN, M.D., M.R.C.P.

AND

E. FECITT, M.P.S.

(Brighton County Borough Mental Hospital, Haywards Heath)

The facility with which copper combines with active phosphorus to form copper phosphide has been the basis of most methods of first-aid treatment of persons contaminated with phosphorus. The standard treatment suggests that the burning phosphorus should be extinguished with water, keeping the burned area damp and removing the patient to hospital for surgical attention as quickly as possible. The burn is treated with aqueous solutions of sodium bicarbonate and copper sulphate.

The principal objections to this treatment are that such solutions are cumbersome to carry and are not likely to be immediately available in civil defence and active service conditions, although speedy application is, of course, all-important. Also, the number of persons contaminated may be so large that immediate active surgical attention to all is not possible, and in the meantime it is necessary to repeat the application of the solution—not the best treatment for an already shocked patient. There is, further, the danger that repeated applications of fluid may wash particles of phosphorus to the periphery, with the risk of peripheral burns.

The possibility of damage to this institution by phosphorus-containing incendiaries during air attacks and the prospect of having to deal with a number of casualties among our population led us to investigate this matter with a view to producing a substance which fulfilled the following requirements: (*a*) it should be readily available in a compact form; (*b*) all the remedies should be contained in one compound; (*c*) it should immediately extinguish the phosphorus and inactivate the products of phosphorus combustion—i.e., phosphorus pentoxide and phosphoric acids; (*d*) it should be viscous and stick to the skin so as to remain in position, and also hold the particles of phosphorus *in situ*; and (*e*) it should be easily removed by warm water.

Godding and Notton (1942) suggested the use of copper sulphate, glycerin, and starch. Tomski (1943) recommended for trial two creams, the first containing 20% of sodium bicarbonate, and the second copper both as oleate and as sulphate. Tomski suggested that the two creams could be carried by fire guards, wardens, etc. Goldblatt and Oakeshott (1943) considered that aqueous solutions of copper sulphate would be unlikely to interact with solid phosphorus or with phosphorus dissolved in some solvent not miscible with water to produce total inactivation of the phosphorus. They suggested the use of copper oleate, with which they combined a rubber solvent.

One of us suggested the use of sapo mollis *B.P. Add. III* as the base for incorporating copper sulphate, and after many trials a compound was prepared with a final content of 4% copper salts. The damage to tissue by burning phosphorus is thought to be due not only to the heat of combustion and to the corrosive action of phosphoric acids formed as the terminal result of such combustion but also to the intensely hygroscopic action of phosphorus pentoxide, which is the intermediate stage of the change. Phosphorus pentoxide "mops up" water with great avidity and with the production of intense heat, and we suggest that, applied to the skin, a film of water sufficient to extinguish the phosphorus flame will not be adequate to provide the pentoxide with enough water to supply its needs; thus tissue fluid is called on, causing further damage. For this reason a high proportion of water was mixed with the compound. It was also felt that water loosely held in depth over the area by such a compound might act as a better conductor of heat than air and that in this way the heat generated by the change—$P_2O_5+3H_2O \rightarrow 2H_3PO_4$—would be more easily removed from the site of the injury. The method of production of the copper-soap compound is described later.

Bench and personal trials showed that the compound was extremely quick in action. Burning phosphorus was extinguished immediately and phosphide formation was very rapid. It also appeared to us that the inactivating layer of copper phosphide on the surface of a piece of phosphorus was of greater depth than with the copper sulphate solution. The black phosphide particles were very clearly visible in the green mass of the compound, giving an excellent colour contrast, and this may be important, where manual removal in the operating theatre afterwards is necessary. The compound is adhesive and remains *in situ*, but is easily washed away with warm water.

Through the co-operation of the Ministries concerned, arrangements were made for tests to be carried out on experimental burns, and we are deeply indebted to Prof. G. R. Cameron and Mr. F. Burgess for their reports and for permission to publish them.

REPORT I

Treatment of Experimental Phosphorus Burns with Copper Sulphate Soap (Prof. G. R. Cameron and F. Burgess)

Adult rabbits (2 kg. body weight) were given standard phosphorus burns on the shaved skin of their backs. Under nembutal anaesthesia, 0.1 c.cm. of a 50% solution of yellow phosphorus in carbon bisulphide was applied to an area of skin enclosed by a metal ring 19 mm. in diameter, ignited, and allowed to burn for 15 seconds. Such burns are remarkably similar in depth and reaction, and heal in about 5 to 6 weeks when treated simply by water application. Two such burns were made on each rabbit—one being treated at once by repeated application of the copper sulphate ointment, which was renewed until it failed to turn brown or black, the other burn serving as a control and treated in some instances with water alone, some with the standard sodium bicarbonate–copper sulphate solution method (*Medical Manual of Chemical Warfare*, 1943, p. 50). In a third group the copper sulphate ointment was compared with copper sulphate ointment followed after two hours by 2% solution of sodium bicarbonate. In all instances the ointment was allowed to remain on the burn for several days. Comparison of healing times, judged by separation of the scabs which invariably form on the burnt surface, was adopted as the measure of effectiveness of treatment. Results are shown in Table I. It is apparent that the ointment-treated phosphorus burns heal more rapidly than burns treated with water or with the standard sodium bicarbonate—copper sulphate solutions. In the latter case there was as much as a fortnight's difference in healing times; in the former, nine days. These results are statistically significant.

With the third group of experiments, in which application of copper sulphate ointment was contrasted with ointment application followed after two hours by removal of ointment with sodium bicarbonate solution, the procedure was changed. All animals were killed on the 28th day, when healing was nearing completion, and the burns examined microscopically. The notes in Table I bring the main findings into contrast. There is no doubt that the follow-up of copper sulphate ointment application by washing with 2% sodium bicarbonate solution has aided healing; the bicarbonate solution is also excellent in removing the ointment if cleaning up of the burnt area is desired.

One striking effect of the ointment is the marked tissue reaction seen during the first 24 hours around phosphorus burns so treated. We examined microscopically the burns of five rabbits at this stage and found a great deal more oedema and cell infiltration than in burns treated by other methods. It is possible that an excessive reaction might have its disadvantages; it might lead, for instance, to more pain if the oedema were confined under tension, or it might predispose to secondary infection. But it has not led to interference with healing; on the contrary, the ointment-treated burns have healed more rapidly than those with other treatments, accompanied though they are with less initial reaction. Perhaps the ointment has evoked a useful counter-irritation effect; but this is purely conjecture.

TABLE I.—*Healing of Phosphorus Burns with Various Treatments*

Rabbit	Healing Times in Days	
	Copper Sulphate Ointment Treatment	Water Treatment
810	22	19
811	20	20
812	19	20
813	20	20
1594	26	55
1595	27	56
1596	34	42
1597	26	40
1628	27	31
Mean ..	24·6	33·7

	Copper Sulphate Ointment Treatment	2% Sodium Bicarbonate + 1% CuSO, Treatment
1654	31	31
1655	24	45
1656	24	45
1657	33	47
1658	31	45
Mean ..	28·6	42·6

	Copper Sulphate Ointment Treatment	Copper Sulphate Ointment followed after 2 Hours by 2% Sod. Bic.
	Microscopical Findings 28 Days After Burning	
1837	Very large epidermal defect, large scab, little dermis reaction	Moderate epidermal defect, small scab, little dermis reaction
1838	Large epidermal defect, large scab, little reaction	Completely healed over
1839	Almost complete healing, very little dermis reaction	Complete healing, but epidermis thin, little reaction
1840	Moderate epidermal defect with scabbing, little dermis reaction	Healing nearly complete
1841	Scab attached to two small epidermal gaps, little dermis reaction	Scab attached to one small epidermal gap, little dermis reaction

We conclude from these experiments that copper sulphate ointment, in addition to being an excellent first-aid measure for phosphorus burns, is of value in the healing stages also, since it has reduced the healing time of burns in striking fashion. We would suggest that it be combined, in subsequent treatment, with sodium-bicarbonate solution; for the latter allows of the easy removal of the ointment if the burn is to be inspected, assists in the disposal of any phosphorus which may still persist after ointment treatment, and tends to reduce the healing time of the burns.

Trials of preparations of this type involving emergency methods are extremely difficult to arrange. We are, however, informed by Surg. Capt. Fairley that at the time of the trials of the compound a scientist sustained a badly mangled hand due to a phosphorus grenade exploding in his hand. There was very serious tissue laceration of one hand and the loss of several phalanges of both hands. Burning phosphorus was embedded in the lacerated tissues of one hand. The compound gave excellent results, and after the patient's removal to hospital for urgent surgical treatment the soapy character of the first-aid application allowed his various injuries to be quickly cleaned up before operative treatment was undertaken. The surgeons made favourable comment on this.

The compound was issued in this hospital in wide-neck glass jars each holding half a pound. The mouths of the jars are 3 in. in diameter, thus enabling the operator to insert his fingers and obtain a sufficient quantity at once.

A sample of a German paste preparation suggested by H. Stadlinger (1944) was prepared and forwarded for examination. A comparison of this German paste and the copper-soap compound was made, and was reported on as follows.

REPORT II

Treatment of Experimental Phosphorus Burns with a German Paste (Prof. G. R. Cameron and F. Burgess)

This paste (Stadlinger, 1944) contains $CuSO_4$ 2 parts, bolus alba (i.e., kaolin) 70 parts, and water 100 parts. The following tests were carried out in order to compare Stadlinger's paste with the $CuSO_4$ ointment of McCartan and Fecitt, as well as with water treatment. Groups of 10 rabbits were used. Under nembutal anaesthesia 0.1 c.cm. of a 50% solution of yellow phosphorus in carbon bisulphide was applied to an area of rabbits' skin enclosed by a metal ring 19 mm. in diameter, ignited, and allowed to burn for 15 seconds. Two such burns were made on each rabbit, one being treated at once by repeated application of the British $CuSO_4$ ointment, the other being treated with Stadlinger's paste, applied repeatedly until discoloration of it ceased. In another series of rabbits the Stadlinger paste method was compared with water treatment. Comparison of healing times, judged by separation of scabs which form on the burnt surface, was adopted as a measure of effectiveness of treatment. Results are shown in Table II. In addition, microscopical comparison of burns variously treated, and examined after 24 hours, was carried out to determine initial reactions to the treatment.

TABLE II.—*Healing of Phosphorus Burns After Various Treatments*

Rabbit	Healing Times in Days	
	British Copper Sulphate Ointment Treatment	Stadlinger Paste
4231	23	32
4232	23	32
4233	23	42
4234	32	45
4235	35	45
4241	23	37
4242	23	37
4243	24	37
4244	24	38
4245	28	38
Mean ..	25·8	38·3

	Water Treatment	Stadlinger Paste
4226	42	27
4227	34	27
4228	37	42
4229	38	45
4230	50	45
4236	50	34
4237	42	37
4238	44	37
4239	44	37
4240	44	41
Mean ..	42·5	37·2

The mean healing time for burns treated with the British $CuSO_4$ ointment was 25.8 days, for the Stadlinger paste 38.3 days. The difference is significant. In the second group of rabbits the mean healing time for burns treated with water alone was 42.5 days, for the Stadlinger paste 37.2 days. This difference is barely significant. The cheering result of the investigation seems to be that the British $CuSO_4$ ointment is much better than the Stadlinger paste in promoting healing, while the latter has little advantage over water treatment. Microscopical examination of burns 24 hours after treatment showed somewhat more inflammation with the Stadlinger paste than with the British $CuSO_4$ ointment. The $CuSO_4$ ointment is very much easier to apply and remove than the Stadlinger paste. Secondary infection was not seen in any of these experiments.

We conclude that the British $CuSO_4$ ointment is much superior to the German paste.

Preparation

For convenience in handling the compound was made in ½-lb. lots. A 25% solution of copper sulphate in water was prepared and the requisite amount of this to give a final content of 4% copper salt was heated in a boiling-flask. Sapo mollis was heated in a water bath, and the copper sulphate solution was added hot by constant trituration on a slab. Copper precipitates as oleate, and this is thoroughly incorporated into the base between each addition. It is advisable to add the copper sulphate solution in small successive portions. The resulting compound is a tacky homogeneous mass, and samples have kept very well for at least twelve months. The *p*H of the final compound, determined electrically, is 8.65 at 19° C. and 8.24 at body temperature.

Sapo mollis *B.P. Add. III* is described as the sodium or potassium soap of a suitable vegetable oil or oils or the fatty acids therefrom, other than coconut oil, palm-kernel oil, or their fatty acids. The sapo mollis used in the above preparation was supplied by British Drug Houses Ltd., and has proved very consistent and suitable for the purpose.

British Drug Houses Ltd. sent us an analysis of the sapo mollis as follows: 51.7% of fatty acids, as compared with the *B.P.* recommendation of not less than 44%. The fatty acids have a solidifying point of 17° C. (*B.P.* not higher than 31° C.), an acid value of 191.5 (*B.P.* not greater than 205), and an iodine value of 146.5 (*B.P.* not less than 83). Resin acids are absent. The soap contains no free alkali hydroxide and no free fatty acids. The total free alkali, calculated as Na_2CO_3 in 10 grammes, is equivalent to 0.2 c.cm. N/1 sulphuric acid, as against the *B.P.* limit of 1 c.cm. N/1 acid.

Conclusions

The copper-soap compound is an effective first-aid treatment of phosphorus burns.

Being a viscous and compact substance, it can be carried about easily by nurses, fire guards, etc.

In experiments, using the copper-soap compound, the healing time of wounds was substantially reduced as compared with the standard treatment.

We express our thanks to Prof. Sir Francis Fraser, Director-General of the Emergency Medical Services, and to Mr. J. B. Hunter, F.R.C.S., Sector Hospital Officer, for their great interest and help. We gratefully acknowledge the work of Prof. G. R. Cameron, Mr. F. Burgess, and Lieut.-Col. Collumbine, who carried out experiments; and also the arrangements made by Surg. Capt. A. Fairley. We are much indebted to the Medical Research Council for the help given us through Dr. F. H. K. Green and members of the Burns Subcommittee. We also wish to record our appreciation of the helpful advice and criticism given by Mr. R. F. Nunn, B.Sc., biochemist to this hospital.

GLOBIN INSULIN: CLINICAL TRIAL

BY

J. M. MALINS, M.B., M.R.C.P.

In the present trial globin insulin (G.I.) has been used in single daily doses in 36 cases, of which 33 had had no previous treatment. All the patients gave a history of acute onset of diabetes with thirst and wasting. The diet was approximately the same for all; it contained 180 g. of free carbohydrate with an average proportion of protein and fat, and allowed patients to use the normal resources of the home kitchen or works canteen. The carbohydrate was spaced as follows: breakfast, 50 g.; dinner, 50 g.; tea, 30 g.; supper, 50 g. The range of insulin dosage was 10 to 40 units, with an average of 24, the injection being given half an hour before breakfast.

Results.—(*a*) In 10 cases perfect control, both clinical and biochemical, was obtained. The health remained normal, the blood sugar did not rise above 180 mg. per 100 c.cm., and the urine contained not more than a trace of sugar. The average dose of G.I. in this group was 20 units. It is notable that seven of these ten patients were regarded as exceptionally co-operative. (*b*) In 16 cases control was only fair. Hyperglycaemia and glycosuria persisted, although the weight and general health were on the whole maintained. The main difficulty in this group was the frequent occurrence of insulin reactions, even when the dose of insulin was increased only to control the symptoms while hyperglycaemia persisted. Six of these cases have been changed to a P.Z.I.-S.I. mixture with satisfactory results. (*c*) In 10 cases the control was certainly inadequate and diabetic symptoms persisted—e.g., pruritus, weakness, or occasional thirst. Five of these have been changed to a P.Z.I.-S.I. mixture, and the others will almost certainly be treated likewise in the near future.

Hypoglycaemia.—Eighteen patients complained of insulin reactions, the symptoms in general being those common with S.I.—sweating, trembling, weakness, and hunger, relieved at once by food. In 12 cases the symptoms occurred between 11 a.m. and noon (four to five hours after the injection). In three cases the symptoms began at 6 p.m. and headache and weakness were outstanding, while relief from food was not immediate—features which resemble the P.Z.I reaction. In one case the incidence was at 4 p.m., in the other at 8 p.m., and one man stated that he felt identical symptoms twice in one day—at 11.30 a.m. and 6 p.m.—which must be a rare event with any type of insulin. Local reactions occurred in two cases only, and were transient.

Blood-sugar Readings.—In 11 in-patients the blood sugar was studied throughout 24 hours at approximately two-hourly intervals. The diet was that described above and the average dose of G.I. was 24 units. The results were inconstant, but three average curves are shown (Figs. 1–3) which suggest that with increase of dosage of G.I. the insulin activity is delayed in onset and prolonged. (1) With 16 units hyperglycaemia occurred after breakfast, but not after the midday or evening meals, while the fasting blood sugar was well above normal the next morning. In this particular case good health was maintained for six months on this regime. (2) With 32 units there was still hyperglycaemia after breakfast, but later in the day (15 hours after the injection) the blood sugar fell to dangerous levels, while the fasting sugar next morning was not grossly raised. (3) With 40 units hyperglycaemia occurred after breakfast and the midday meal, the insulin action being delayed, with very low figures throughout the early hours of the following morning (lowest figure 24 hours after injection).

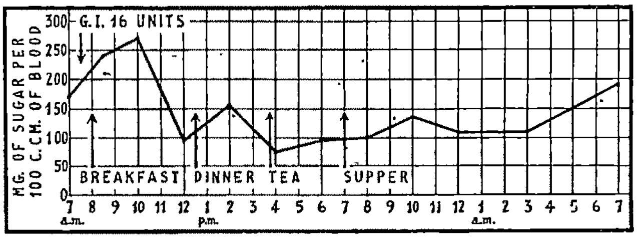

FIG. 1.—Blood-sugar readings with 16 units of G.I.

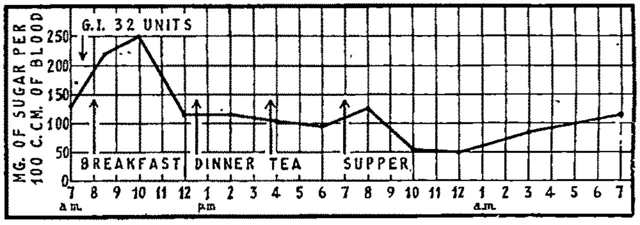

FIG. 2.—Blood-sugar readings, 32 units G.I.

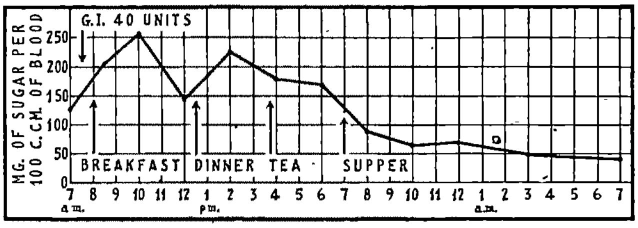

FIG. 3.—Blood-sugar readings, 40 units G.I.

Discussion

The action of G.I. has been compared with that of other insulins under experimental conditions by Bauman (1939) and Duncan and Barnes (1941), and in both papers was found to be intermediate between P.Z.I. and S.I., with maximum hypoglycaemic effect eight hours after the injection. In clinical use it has been commended by Bauman (1939, 1940) and Andrews and Groat (1940), who were able to control mild and moderately

ately severe cases requiring less than … for those who are regular in their dietetic habits. … absence of local reactions may be an indication for its use instead of P.Z.I.

Summary

The results of treatment with G.I. in 36 diabetic patients are described. The greatest drawback to its use has been the frequency of hypoglycaemia. G.I. is considered to have a limited place in the treatment of mild and moderately severe diabetes.

I would like to thank Dr. A. P. Thomson and Dr. G. H. Knight, under whose care these patients were treated.

A CASE OF PARAPLEGIA AFTER CEREBROSPINAL MENINGITIS

BY

H. HILTON STEWART, M.D., M.R.C.P.

Paraplegia is one of the many nervous complications of cerebrospinal meningitis, and may be organic or functional (Rolleston, 1919). Most cases occur during the course of the acute phase of the disease and gradually tend towards recovery, although permanent paraplegia is recorded. The pathology may be pressure on the cord due to exudate, haemorrhagic or purulent, and not matting of adhesions or a diffuse meningomyelitis (de Massary and Chatelin, 1910). Lesions localized both to the brain and to the spinal cord have been described (Ribadeau-Dumas *et al.*, 1938).

Onset of paraplegia after the acute phase of the disease has passed off does not seem to have been recorded, but a case of syringomyelia occurring four months after cerebrospinal meningitis has been observed (Guillain *et al.*, 1939). The case here reported is therefore unique in that it occurred one year after the acute phase of the meningitis, and was due to organized adhesive meningitis causing diminution of the blood supply to the mid-dorsal area. Division of these adhesions presumably restored the blood supply, and function very slowly recovered. It must be excessively rare for any spinal compression case to make complete recovery after an interval of 1½ years from the removal of the obstruction, but such is the fact in this case, and the only departure from normal demonstrable in this patient now is a scar on her back.

Clinical History

A child about 12 years old was admitted to Lurgan and Portadown District Hospital isolation ward on March 29, 1940, suffering from acute meningitis. While no meningococci were cultivated, the C.S.F. was slightly turbid and contained pus cells, and was thought to be definitely meningococcal. She was treated with a full course of sulphapyridine orally and antimeningococcal serum intravenously. Her affection ran a subacute course and she was in hospital 5½ weeks, being discharged cured on May 14, 1940.

In March, 1941, the patient began to have difficulty in walking. She first noticed that her right foot was trailing and catching the ground so as to trip her. The weakness gradually increased in both legs. The only other symptom was difficulty in starting micturition. She was admitted to Lurgan and Portadown District Hospital on

and no pus cells. The culture showed …

The sensation now altered, and for a time the patient's replies were unreliable. From the umbilicus upward, sensation was normal; but downwards from the umbilicus sensation became progressively worse until the mid-thigh was reached. From there to the periphery sensation was almost lost. Radiographs of the spine were normal.

On May 28 2 c.cm. of lipiodol was injected into the cisterna magna, and the opaque material was found to be held up at the lower border of the body of the 9th dorsal vertebra. Radiographs six days later showed no further descent of the lipiodol.

On July 3 a spinal exploration was carried out by Mr. W. W. Bassett. The spines of the 3rd to 9th dorsal vertebrae were removed. The dura was exposed and incised vertically, but the arachnoid failed to bulge out. It seemed as if the latter were adherent to the surface of the pia, for the usual "floating" appearance of the cord in the C.S.F. was not seen. The slit in the dura was extended downwards, but no other obstruction was found. About the level of the 7th dorsal vertebra the posterior aspect of the cord looked pale. The adhesions between the dura and arachnoid were separated by blunt dissection, and it was concluded that the lipiodol hold-up had been due to these adhesions. The dura was closed without opening the arachnoid. The patient made a good recovery from the operation, but no improvement occurred in the legs. On Aug. 1 it was noted that they were still spastic. Muscle and joint sense was gone. Vibration sense was present, reflexes were increased, and plantars were still extensor. Pressure sores developed on the skin of the heels.

No further recovery ensued, and the patient was transferred to her home to be nursed there. Nothing more was heard from her until Jan. 18, 1945, when she walked up to the hospital to allow me to examine her. Her subsequent history is interesting.

It is now 3½ years since the operation. Three months after leaving hospital sensation slowly began to return. She lay in bed unable to move for 1½ years after operation and then began to move her legs. Shortly after this she started to crawl around the house. This stage lasted three months, and then she got two sticks and walking improved further. The sticks were used until Sept., 1944, since when there has been no disability. Her longest walk up till now has been three miles, but she says she could go much further. Examination showed no spasticity in either leg and no wasting; co-ordination was normal. Sensation to all forms was normal. The reflexes were present and equal and the plantars were flexor. The cranial nerves and upper limbs were also normal. Apart from the healed wound on the back it would have been impossible to say that the patient had ever had spinal compression.

I am indebted to Mr. W. W. Bassett, F.R.C.S., surgeon at Lurgan and Portadown District Hospital, for his valuable help in this case.

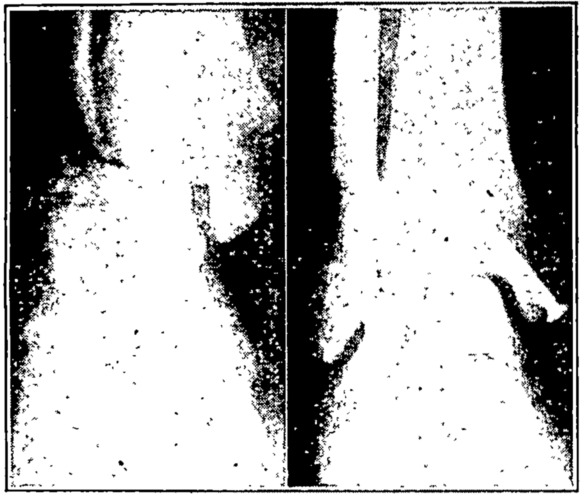
A report in the *Scotsman* states that the trustees of the Nuffield Provincial Hospitals Trust have agreed to make a substantial annual grant for a period of years towards the work of the rehabilitation department of Glasgow Royal Infirmary. The grant will be used to establish associated clinics in some of the outlying parts of Lanarkshire and neighbouring counties. It has been found that many patients attending the department did not complete their treatment at the Infirmary owing to difficulties and expenses of travel, and the new clinics should be of great value in encouraging patients to attend for the follow-up treatment and regular examination essential to the restoration of injured workers to full capacity for work. The facilities of the clinics will be available to all patients irrespective of the hospital they may be attending.

[illegible] reduction of the vast majority of these fractures meets with only partial success. The chief factor militating against anatomical reduction is the [illegible] of the [illegible] covering of the malleolus into the gap between the fragments in a tense curtain-like fold. In the fortunate ones this fold does not extend as deeply as the cartilaginous surface, and union of the deeper part of the malleolus next to the joint restores the mortise of the ankle. In those less lucky, particularly where some displacement has occurred, the aponeurotic fold clothes the entire depth of the fracture and fibrous union is inevitable. It is not possible to tell from the skiagrams which cases have this interposed fold and which have not—it has been found here in the great majority of the cases operated on. After excision of the fold the opportunity is taken to obtain anatomical reduction of the malleolus by internal fixation. This minimizes the chance of fibrous union, maintains reduction, and facilitates early active movements and thus a return to full function in minimum time.

Operative Fixation

The operation is not a difficult one, and is best done as early as possible, before reactionary swelling occurs. A study of the lateral *x*-ray view will show whether the anterior or the posterior part of the malleolus is fractured, and the siting of the incision is made accordingly: attention to this apparently trivial point adds considerably to the ease of the operation. The fracture line is exposed, clot cleared, and the aponeurotic curtain excised. Anatomical reduction is now effected, particular care being taken that filleting of the small fragment is not done, because of the danger of subsequent ischaemic death.



The fragment is fixed by a long vitallium screw, which is introduced at a steep angle in order to avoid the angle of the joint mortise. The screw has to be long because of the poor holding quality of the cancellous bone into which it is introduced. Comminuted fractures, or fractures in which the fragment is too small to hold a screw, are not suitable for this method of fixation.

Active movements are started from the very next day, the leg being put up in a right-angled foot splint when at rest. In [illegible] three, five, and six weeks respectively, [illegible] weight at six weeks. The remaining four had fractures of the external [illegible] malleolus at varying levels, obtained full movements at an average of two and a half weeks, and took full weight at an average of seven weeks. Any associated external malleolar fracture or diastasis of the inferior tibio-fibular joint is not directly treated. Since the internal and external lateral ligaments are intact, the anatomical reduction of the internal malleolus pulls the astragalus into place, and this in turn reduces the external malleolus.

Summary

The cause of fibrous union which occurs in many fractures of the internal malleolus is an aponeurotic curtain-like fold interposed between the fragments.

Internal fixation following excision of this fold is recommended as a measure to ensure union, to obviate the use of external fixation, and to restore early function.

The method of operation is described and the results of 20 cases are given.

Medical Memoranda

Partial Atresia of the Cervix complicating Pregnancy

The case recorded below, which came under my care, may be thought interesting enough to merit publication.

CASE HISTORY

A primipara, aged about 27, was admitted on May 28, 1944. She had been carried to Calabar from a neighbouring village by canoe. On admission she gave a history of full-term pregnancy and of labour pains, which were said to have begun four days previously, but at the time of admission the labour pains had ceased. She was lightly built, emaciated, and appeared toxic. Temperature 102.4° F., pulse 144, respirations 24, and blood pressure 100/60. Pelvic measurements were: I.C. 9 in.; I.S., 8 in.; E.C., 7 in. On abdominal palpation the uterus was found to be tense and tender. The fundus was four fingers below E.C., with vertex presentation and left occipito-anterior position. The head was well down in the pelvis. Thirty-six ounces of urine was withdrawn by catheter: it was highly concentrated, with a heavy cloud of albumin; sugar was not present.

Vaginal examination showed oedema of the labia: the clitoris was normal. The vagina was about 2 in. in length and led to a blind alley, formed by the partially atresic cervix. In place of the external os were two "pin-hole" openings, about 3/4 in. apart. Through these small holes a few strands of the infant's hair were protruding, and very offensive liquor amnii was trickling out.

Treatment.—Under chloroform anaesthesia with gr. 1/100 atropine premedication the cervix was opened with a pair of scissors. Craniotomy was performed, and a female baby weighing 7 lb. 2 oz. extracted. The placenta was removed manually. Bubbles of gas and very offensive material came from the uterus on extraction of the placenta. There was brisk bleeding, but this was quickly controlled by the injection of 1 c.cm. of pituitrin. The foot of the bed was kept raised for six hours, and one pint of submammary saline given.

Subsequent treatment consisted of injection of one ampoule of soluble sulphapyridine, followed by two tablets of sulphapyridine four-hourly. As the temperature had not settled down by the end of the first week and the patient's condition was still unsatisfactory, sulphathiazole was administered in doses of two tablets four-hourly. The temperature settled down three days after giving this drug. Apart from oxytocic drugs, sedatives, and tonics, repeated administration of anti-gas-gangrene and antitetanus sera was found necessary. Local treatment consisted of a daily intra-uterine douche with 1 in 320 dettol followed by insufflation with powdered sulphapyridine.

The woman was discharged from hospital exactly one month after admission, June 28. At the time of her discharge she appeared to have gained weight, and she had completely recovered.

COMMENTS

This was undoubtedly a case of congenital partial atresia of the cervix, as there was no history of previous infection or trauma to suggest closure of the cervix by scar tissue or any evidence of scarring. I consider this case of peculiar interest in view of the generally accepted view that in this type of abnormality the internal genital organs are too much underdeveloped to permit of fertilization.

At this station one has no access to the literature, but I doubt if many such cases as the one described above are recorded.

I am indebted to the Director of Medical Services, Nigeria, for permission to publish this case report.

Medical Officer in Charge. Maternity Hospital, Calabar.

Spontaneous Rupture of Rectus Muscle

Haemorrhage into the rectus sheath may result from a direct blow or a severe muscular strain, but there is the so-called "spontaneous" type, the cause of which is not so obvious. This latter condition is rare, and most surgeons of wide experience have seen few cases. It is well known that certain febrile diseases are complicated by muscle degeneration and that this may predispose to rupture of the muscle. Thus Virchow in 1857 described the rupture got in typhoid fever, and gave a detailed account of the hyaline degeneration present—a condition which later became known as Zenker's degeneration. Snyder (1939) has pointed out that the condition is also not uncommon in respiratory infections, especially influenza, and was noted during the epidemic in 1918. Haematoma of the rectus sheath is also found occasionally after the termination of pregnancy, and Torpin (1943) has summarized 27 cases which come into this category and has added one of his own.

The following is a case of haematoma of the rectus sheath which shows some unusual features and is worth recording:

CASE HISTORY

A carrier aged 36 was admitted to hospital with a painful swelling on the right side of the abdomen. Two weeks previously he had been suffering from boils on the side of his neck, and found about this time that he was having slight twinges of pain in the right side of the abdomen when he was cranking his motor lorry. The pain continued, but was never severe enough to prevent him from starting his lorry each morning. About a week after the pain had begun the patient noted a fullness in the right side of the abdomen. A few days later he found that there was a definite swelling present, and this enlarged up to the day of admission.

The patient was a healthy, well-nourished man who did not seem to be suffering much pain. There was a tender mass the size of a fist lying to the right of and slightly below the umbilicus. The condition was diagnosed as a rupture of the rectus muscle, and it was decided to operate and repair it. This was done on the day after admission. Under general anaesthesia an incision was made over the swelling. The rectus sheath was found to be distended with partially clotted blood and, after this had been evacuated, a transverse tear 1 cm. long was found 1.5 cm. below the level of the umbilicus. Suture of the tear was impossible because of the friability of the muscle, and the rent was thus made into a longitudinal one by removing small segments of muscle above and below; it was then sutured transversely. The patient made an uninterrupted recovery.

The pieces of muscle removed were examined histologically. The muscle fibres were swollen and the striations were absent, the appearance resembling that of Zenker's degeneration. Much blood-clot was seen extending between the fibres.

DISCUSSION

There are three interesting features about the case. First, the condition appeared to start during the time the patient was suffering from a septic process; secondly, the trauma applied to the rectus was not such as would normally rupture the muscle; and, thirdly, the histology suggested a degenerative lesion of the muscle fibres, although it is possible that this was due to the ischaemia of the fibres around the tear. It is thus tempting to postulate that the rupture of the rectus was predisposed to by a degenerative process secondary to the septic focus in the neck. It should also be noted, however, that there was some pain in the muscle for almost two weeks before the final large rupture, and it is possible that the repeated slight strains on the muscle caused by cranking a heavy engine had played an important part in producing the muscle degeneration.

ALEXANDER LYALL, M.D., Ch.M., F.R.C.S.Ed.,
Surgeon in Charge, Greenock Royal Infirmary.

Reviews

LEUCOPENIA AND AGRANULOCYTOSIS

Leukopenia and Agranulocytosis. By William Dameshek, M.D. Edited by Henry A. Christian, M.D., F.A.C.P., F.R.C.P.Can. Oxford Medical Publications. (Pp. 74. 10s. 6d.) London: Oxford University Press.

This little book gives an excellent summary of the numerous observations which have been made on the occurrence of leucopenia and agranulocytosis, and at the same time on exposition of our ignorance of the physiological background of these events. "Definite leucopenia" is said to be present when the white blood corpuscles are below 4,000, though it is difficult to impose a standard owing to the variations in the white count in different individuals. Agranulocytosis is defined as an acute disorder characterized by constitutional disturbances, fever, sore throat, and extreme leucopenia. Leucopenia occurs in a variety of conditions, which are enumerated in detail. Agranulocytosis, on the other hand, is due in the great majority of instances to sensitivity to drugs, of which amidopyrine and the sulphonamides are the most important. It is probably an anaphylactic or allergic type of shock phenomenon with sudden arrest of production of granulocytes in the marrow. In the past, treatment has been chiefly concentrated on efforts to stimulate the marrow to make white cells. Therapeutic agents for this purpose have included *x* rays, nuclein derivatives such as pentose nucleotides, liver extract, leucocyte cream, and yellow bone-marrow; transfusions have also been used. The value of these agents has been much disputed, and it would appear that the marrow is already stimulated to a maximum degree by the infection which is present. Dameshek believes that a more rational therapy is to prohibit the offending drug and to endeavour to control the infection by sulphonamides (if the case is not due to sulphonamide sensitivity) or by penicillin. It seems probable, indeed, that penicillin will greatly improve the prognosis of agranulocytosis. So much, then, for empirical data. When we look deeper into the matter we find we know very little about the mechanism of leucocytosis in pyogenic infections, and still less about the leucopenia of virus infections, many protozoal diseases, and many forms of splenomegaly. This has been at any rate partly due to the relative inaccessibility of the bone-marrow; but the recent development of marrow puncture should make investigations easier. We also know very little of the process of sensitization to drugs, though this is a matter of increasing concern with the introduction of chemotherapeutic agents, such as the sulphonamides and thiourea. Dameshek's review is therefore timely in providing a base from which further advances may be made in these important fields of experimental and clinical science.

ALLERGY

Allergy. By Erich Urbach, M.D., with the collaboration of Philip M. Gottlieb, M.D. (Pp. 1,073; illustrated. 70s.) London: William Heinemann. 1944.

Allergy is one of the most loosely used words in medicine: it has even passed into common speech, where it is used in a sense hardly wider or less legitimate. If some definitions of it be accepted the term certainly covers a wide variety of phenomena, and anyone who can formulate principles to explain them is doing an important service. This is the commendable approach to the subject adopted by E. Urbach and P. M. Gottlieb, of the Allergy Service, Jewish Hospital, Philadelphia, in a massive tome of which the first considerable section deals only with fundamental principles and the experimental basis on which knowledge rests. Succeeding subjects are the principles of diagnosis and treatment, "etiologic agents" (which are classified as inhalants, ingestants, injectants, contactants, physical agents, and infectants), and finally the symptomatology and treatment of allergic diseases, which are here classified regionally. The practising physician will find many interesting ideas in this volume, though he may not accept all its doctrines. He may, indeed, be surprised how many commonplace phenomena or actual diseases are capable of explanation on an allergic basis. To invoke such an explanation for exanthematous rashes and a variety of skin diseases and for functional disorders of the respiratory and intestinal tracts is often reasonable enough, but some much more startling attributions will be found here, as may be gathered from the fact that the diseases dealt with include angina pectoris, endocarditis, nephritis, cataract, and gout.

To attempt any critical assessment of the views expressed is impossible in a small compass: it must suffice to say that they are interesting and stimulating if sometimes rather far-fetched. The book is profusely illustrated, thoroughly documented, and evidently based on extensive and exceedingly varied clinical experience.

INTELLIGENCE AND ATTAINMENTS OF CHILDREN

The Scottish Council for Research in Education. Its Aims and Activities. Publications of the Scottish Council for Research in Education, XXIV. (Pp. 38. 1s.) University of London Press, Ltd., Malham House, Bickley, Kent.

The report of the Scottish Council for Research in Education is a valuable and interesting document which includes several points relevant to medical practice. These chiefly concern the intelligence and mental capacity of children, but the findings are of general importance. It is found that both in intelligence and in attainment the small country schools and the large town or city schools compare favourably with medium schools, probably because of more individual attention on the one hand and better organization on the other.

A survey in Fife on a batch of American achievement tests showed that 11-year-old Fife children are 16 months ahead of American children of the same age. A wider survey showed a smaller proportion than was expected of children two or more years retarded. The proportion above the standard, however, was smaller than expected. This may mean that the standard of education is suited only to the brightest children. The best basis for predicting future success seems to be a combination of I.Q. plus qualifying examination plus teachers' estimates (sealed). If only one method is used the examination carefully set and corrected by one competent examiner is held to be best. It was found that 7½% of boys are for all practical purposes colour-blind. Unless special tests are used this generally goes undetected and the children may therefore be misjudged.

Two large surveys of Scottish children have been undertaken, one in 1932 and one in 1935–7. It would appear that the average I.Q. comes very close to 100 for boys, and with girls very slightly less. Exceptional children—i.e., those falling outside the limits of twice the standard deviation—for whom provision would have to be made are less than 5%, half of whom would be subnormal and half supernormal. One gathers that mental deficiency is rather less prevalent in Scotland than in England and Wales. The incidence is much alike in urban and in rural areas, though the interesting fact emerges that the highest average intelligence was found in the Highlands and Islands.

There seems little indication that the mental capacity of a child changes appreciably either through time or through circumstances, but the high scorers by no means always get into occupations suited to their capacity. This is a matter which should engage the attention of those responsible.

NEURASTHENIC STATES

Conceptions et Traitement des États Neurasthéniques. By J. Tinel. (Pp. 63. No price given.) Paris: Librairie J.-B. Baillière et Fils, 19, Rue Hautefeuille. 1941.

It is a real pleasure once again to have for review the work of a French clinician with his countryman's familiar brilliance of clinical description and logical deductions from direct observation. This little book on the neurasthenic states is most worthy of perusal. The author at first deprecates the use of the word "neurasthenic," but confesses that no other term is so expressive of the asthenic psychoneuroses which are so familiar in our hospitals and consulting-rooms. He regards the condition as a mixture of psychic disturbance and nervous disability characterized by a subjective fatigability which, however inconstant and variable it may be, is a real fatigue though it may not be demonstrated by specific ergographs, memory or concentration tests, and the like. The patients are essentially egocentric and are characterized by an obsessive hypochondriacal attitude. They exhibit certain physical disturbances such as headache, backache, insomnia, giddiness, paraesthesia, and disturbances of the digestive, respiratory, cardiovascular, urinary, and genital systems—the psychosomatic syndromes of modern terminology—and at the same time are depressed and retarded. The condition has been regarded by some, especially by Dejerine, as due to emotional shocks or prolonged states of disturbances of feeling and curable by faith, and by others as true psychoses—i.e., constitutional, possibly toxic, tending to phasic repetition and not amenable to direct therapeutic intervention: in fact mild and aberrant forms of psychotic depression. Although these concepts are contradictory, Dr. Tinel thinks they are both true: that on the one hand the sensibility to emotional influence is constitutional, and on the other hand the intervention of emotional situations may produce a condition leading to repeated attacks and permanent changes.

The author points out the dangers of thinking the condition is organic and wasting the patient's time, money, and confidence in senseless repetition of investigations and treatment. Equally dangerous and unjust is to describe the symptoms as imaginary; as Dejerine said, they are artificial but not imaginary. In treatment Dr. Tinel favours symptomatic therapy by appropriate physical and medical methods, and discusses the difficulties of achieving an automatic balance by pharmacological means. But causal treatment must be by psychotherapy. Crude suggestive methods, and in all but a very few cases deep psycho-analysis, are deprecated. What is required is sympathy and clear explanation so that the patient realizes the meaning of his illness and the nature of his own personality. Perhaps there is little new in this, but the presentation is so clear and so commendably brief that it is to be recommended to all doctors.

Notes on Books

We have received from Messrs. Taylor and Francis Ltd., Red Lion Court, Fleet Street, London, E.C.4, the *Annals of Science*, Vol. 5, No. 3, July, 1945. This admirably conducted journal began as a quarterly in 1936 and is devoted to the history of science since the Renaissance. It was compelled to cease publication in 1942 in the midst of its fifth volume. We welcome the continuance of this volume. Dr. Sherwood Taylor, in a clear and well-illustrated article on "The Evolution of the Still," trespasses rather beyond the special period of the *Annals*, but throws much light on this subject in tracing the history of this instrument from the early Christian centuries to modern times. Dr. K. J. Franklin, equally well known for his historical studies and his researches on the vascular system, in a description of a seventeenth-century theory on the foetal blood flow, gives a new view on the scientific quality of the French Académie at the time. Prof. J. R. Partington, our leading authority on the history of chemistry, deals with the familiar ground of hydrocarbon flames and records milestones in the advance of knowledge of the subject. The number is completed with articles by Dr. Millington on "Theories of Cohesion," Dr. Dobbin on the "Discovery of Phosgene Gas," and Prof. Patterson and Dr. Buchanan on the crystal forms of the tartrates. Dr. McKie and his fellow-editors are to be congratulated on having maintained so high a scientific standard in the very difficult times in which the *Annals* has recommenced its career.

Essentials of Local Anaesthesia in Dentistry, by A. CORNFORD BOWDEN, is published at 6s. by John Wright and Sons, of Bristol. This small book condenses into 50 pages the essentials of dental analgesia and has been written to help the dental student in his study of the anatomy and innervation of the teeth and jaws. It is wisely emphasized that most dental extractions and fillings can be carried out under a simple infiltration anaesthesia, or in the case of the lower jaw by an inferior dental nerve block. A clear technique is given for the last-named injection, which has become so popular and useful during recent years.

Some local authorities may be applying to be allowed to continue in peacetime a limited service of British Restaurants, mainly for the use of industrial and commercial workers. *Community Restaurants in Design*, published by the London Council of Social Service, 7, Bayley Street, London, W.C.1, at a price of 2s. 6d. post free, sets out two plans considered suitable for such restaurants. Local conditions would probably entail modification of either plan, but it is suggested that the principles embodied in them should be seriously studied by organizers and designers of separate restaurants, or of restaurants incorporated into other buildings. The architectural designs are presented in two coloured plates, and should be studied in conjunction with the written report. The booklet is written by F. le Gros Clark, with designs by L. H. Bucknell and Ruth Ellis, and a foreword by Sir Wyndham Deedes.

BRITISH MEDICAL JOURNAL

THE DISSEMINATION OF POLIOMYELITIS

The mode of transmission of acute anterior poliomyelitis remains in some doubt in spite of the attention given to the subject since the disease was first recognized as communicable by Medin in 1890. In its endemic form infantile paralysis behaves like any other disease of low invasiveness which may gain entry either by the respiratory, or the alimentary, or the cutaneous routes. The virus appears to be widespread, and it is believed that many harbour and disseminate it without showing the usual manifestations of the disease, so that the source of infection is almost never traced and the channel or vehicle cannot be ascertained. In most epidemics the links between paralytic cases are not obvious, although the Victoria outbreak of 1937-8 differed in this respect, and multiple cases in houses are uncommon. Careful inquiry during an epidemic usually reveals contemporaneous febrile illnesses of an indefinite type, often in members of families in which there is a paralytic case, which may be, and probably are, poliomyelitic infections. If these be accepted as infective poliomyelitis without such destruction of nerve cells as causes paralysis, the course of an epidemic is compatible with case-to-case infection. The summer and autumn season at which poliomyelitis prevails is, however, different from that of the common air-borne infections, and this has led epidemiologists to doubt whether it belongs to this group. The fact that it is not a disease in which gastro-intestinal disturbance predominates made them look first for an insect vehicle rather than alimentary channels of infection, although a few small epidemics in America pointed to milk, and Aycock's careful epidemiological analysis of the Broadstairs and Ramsgate outbreak of 1926, which led him to believe that it was milk-borne, has not received the attention in this country which it deserves.[1] The biting stable-fly (*Stomoxys calcitrans*) seemed a possible carrier of the infection, at least under experimental conditions, but this has never been confirmed by the investigation of human outbreaks. The fact that the virus has been isolated occasionally from house-flies is no proof that they play an important part in transmission, and, in any case, they merely act as mechanical agents of alimentary infection.

The experiments of Fairbrother and Hurst[2] in 1930 and subsequent work in America by Faber and Gebhart,[3] indicating that the virus gained entry to and multiplied in the olfactory area of the nasal lining and spread by axonal channels into the brain-stem and cord, sharply turned our minds back to the theory that poliomyelitis is air-borne, especially as it accords with the epidemiological behaviour of the disease if its seasonal incidence is discounted. This view was hardly challenged for ten years, but in the meantime new facts were gathering. The presence of the virus in the faeces of patients and contacts was increasingly demonstrated. Kling and his colleagues in Sweden[4] had found the virus in drinking-water; these workers,[5] and Paul and his colleagues in Detroit,[6] isolated it from sewage. Faecal contamination and alimentary infection could no longer be disregarded. The post-mortem findings of Graeme Robertson during the epidemic in Victoria threw doubt on the olfactory bulbs as a channel of entry, and led Burnet, who had hitherto accepted this route of infection,[7] to say in 1942 that "there can be no real doubt that spread from the alimentary tract to the central nervous system does occur in the individuals who develop paralysis, mild or severe."[8] His view now is that poliomyelitis is an infection of the alimentary tract which may or may not involve the throat. If it does, salivary contamination and droplet spread may play a part, but, as the virus "is liberated in the faeces of all persons with virus infection," particular care should be devoted to training children in the most practical ways of avoiding faecal contamination.

The development of laboratory technique provides a tool which should be capable of forcing a way to more precise knowledge of the spread of infection. H. C. Pearson and R. C. Rendtorff and their colleagues,[9] [10] [11] of the School of Public Health, University of Michigan, have made detailed studies of several groups of sporadic cases in isolated farms, villages, and small towns, and of an epidemic in a large town. Family and remote contacts have been traced, any history of abortive poliomyelitis ascertained, and their stools examined for virus. Insects of many species, rodents and their parasitic insects, faeces from farm animals, and samples of water, milk, and sewage were investigated. The magnitude of the undertaking may be gathered from the facts that in one village where a single case had occurred faecal specimens were obtained from 127 members of all but one of the 39 families living there; in a small town of 1,350 inhabitants where two cases had occurred 282 stools were collected from children under 16 of all but three of the 146 families; in a large town specimens were obtained from 524 persons, including familial and non-familial contacts and persons (374) without known contact; and altogether nearly 10,000 insects of numerous species were examined.

Briefly the results were that virus was isolated most frequently from the faeces of persons who were close family contacts with a known paralytic case, less frequently from those with more remote contact, and very seldom among those who had no connexion with such a case. For instance, during an epidemic in the large town virus was found in members of 6 of 8 households where a case had occurred, the majority of the individuals harbouring it being over 17 years of age; in 8 of 45 households having contact outside the home with paralytic cases; but in only 2 of 127 households whose inmates had no known contact. Positive laboratory findings were not specially associated with a history of indefinite illness. Poliomyelitis virus was not found in any pool of material from insects, animal faeces, water, sewage, milk, or rodent intestines, and only once was a virus of indeterminate character found in a pool of rat brains. Extra-human sources of infection, therefore receive no support from this inquiry. Although the faecal samples were usually collected some time after clinical cases had occurred, and the authors are reserved as to the efficacy of the methods of demonstrating the virus (which they describe in detail), nevertheless the close association of positive laboratory findings with cases of paralytic poliomyelitis strengthens the conviction that infection is from case to case, whether clinical or subclinical, and that the control of the disease depends on early diagnosis and the management of contacts. This accords with the experience of Victoria in 1937–8. Seddon and his colleagues,[12] from their study of the Malta and Gozo outbreak, also concluded that food, water, and insects were not implicated. These writers assumed, however, that dissemination took place by nasopharyngeal droplets and droplet nuclei. It is unsafe to make this assumption from the rapidity of spread and the form of the epidemic wave. The behaviour of Sonne dysentery in this country during the winter of 1937–8 shows that an alimentary infection can follow a similarly rapid course even where there is no common source in the form of food or drink. Diarrhoeal diseases occasionally sweep through even well-conducted children's wards. The living conditions in camps and barracks are somewhat analogous to those in hospital, and if non-immune Service men were exposed to an invasive strain of poliomyelitis virus of which there were numerous hidden foci, it is conceivable that rapid dissemination might ensue by ingestion. From his experience in India, and especially because of the fact that far more officers than other ranks have been affected—the standard of hygiene in officers' mess kitchens as compared with that of other ranks in India being demonstrably lower—D. McAlpine[13] believes that poliomyelitis may be conveyed by food, but that the method of transmission may vary as between one group of cases and another.

MALIGNANT TUMOURS OF THE NASOPHARYNX

Malignant tumours of the nasopharynx have been estimated to comprise only 0.4% of all malignant tumours. The non-malignant form, nasopharyngeal fibroma, is still more rare, and usually seen in males between 15 and 25 years of age; it can be removed, though the operation is severe and bloody. The malignant tumours, however, have not yielded to surgical attack, though every possible form of approach and osteoplastic exposure have been tried. The anatomy of the region discourages this form of treatment. With the failure of surgery we have to rely upon radiotherapy, and it is time to take stock of the results obtained.

A comprehensive study of 454 cases has been undertaken by Erik Godtfredsen[14] (Copenhagen), the records having been drawn from four radiological clinics—those of Copenhagen and Aarhus in Denmark, the "King Gustav V^tes Jubilaeumsklinik" in Lund, and the Radiumhemmet in Stockholm. The period under review extended from 1927 to 1942 inclusive, and attention has been focused on the ophthalmic and neurological complications, estimated at 38% and occurring in 172 of the cases. Many of the tumours were so immature and anaplastic that classification was difficult; the author has adapted that used by Ringertz[15] for carcinoma of the nose: (1) cylindrocellular carcinoma; (2) squamous carcinoma (that is, of epidermal type); (3) metaplastic carcinoma (squamous carcinoma with signs of originating from cylindrical cells which have undergone metaplasia); (4) undifferentiated carcinoma. It is also difficult to classify the sarcomas which arise in the lymphatic tissue of the nasopharynx. Godtfredsen includes here the much-debated lympho-epithelioma, in which Ringertz has demonstrated fibrils by silver impregnation and the transitional-celled carcinomas. The presence of argentophil fibrils is regarded as evidence of mesodermal origin, and the absence of keratosis and the clinical characters, including the pronounced sensitivity to radiation, support this. There is still lack of agreement on this but it was decided to include as sarcomas all tumours appearing to arise in cells of the reticulo-endothelial system. Differences of classification explain the differences in the percentages of carcinoma and sarcoma previously published.

Of the total number (454) of cases 438 were verified histologically: there were 243 carcinomas and 195 sarcomas. There were 172 cases of squamous-celled carcinoma and 166 of reticulum-celled sarcoma. The high proportion of the latter is explained by the classification adopted. There were 61 cases of undifferentiated carcinoma, 17 of lymphosarcoma, and 12 of plasmocytoma. There were a few other tumours of rare type, including one chordoma. About 80% of this series of nasopharyngeal tumours were of the anaplastic type with a low grade of differentiation. Of the 438 verified cases there were ophthalmic and neurological complications in 158; it appears that the squamous-celled carcinomas are particularly apt to invade the base of the skull, generally extending by the foramen lacerum medium. Fifty-three per cent. of all the patients fall into the age group of 41–60, the average age being 49 years—51 for patients with carcinoma and 46 for those with sarcoma. Of the 454 patients 294 were males and 160 females.

The local symptoms of nasal obstruction—discharge and epistaxis—are sometimes overshadowed by the more remote effects. Obstruction of the Eustachian tube causes deafness and effusion into the tympanum, and when the tumour invades the base of the skull palsies may affect any of the cranial nerves. Ophthalmoplegia, neuralgia, headache, paralysis of the palate, larynx, and tongue occur in a variety of syndromes. Enlarged glands in the neck beneath the upper attachment of the sternomastoid may press on the jugular foramen, and the primary focus of disease pass unrecognized. Correct diagnosis is often delayed, and Gordon New[16] recorded that tonsillectomies, intranasal operations of different kinds, operations on the ear and the Gasserian ganglion, dental extractions, and crani otomies have been performed before the diagnosis has been established. To confirm this, *x*-ray examination of the nasopharynx shows an asymmetrical shadow with indefinite outline, dislocation of the upper surface of the soft palate, and evidence of destruction of the base of the skull, particularly in the region of the foramen lacerum medium.

The most common initial palsy—often the first symptom—affects the 6th nerve: next in order are the 5th, the 3rd, and the 4th nerves. Shelden[17] in 1921 drew attention to neuralgia caused by infiltration of the Gasserian ganglion. Paralysis of the hypoglossal may appear with symptoms of pressure on the jugular foramen. Paralysis of the 7th nerve is rare, as also is paralysis of the sympathetic. The commonest initial symptom, however, is enlargement of the cervical glands (especially in sarcoma), followed by aural, nasal, and neurological symptoms (especially in carcinoma).

X-ray examination showed that destruction of the base of the skull is five times as frequent in cases with as in those without ophthalmic and neurological symptoms. That no bone destruction could be demonstrated in some of the former may be due to invasion of the cranial cavity through the basal foramina, as Shelden described. Destruction of bone without cranial-nerve palsies is explained by limitation of the process to the base of the pterygoid process. The destruction is nearly always unilateral and in the neighbourhood of the foramen lacerum medium (spheno-petrous fissure), so that the tip of the petrous portion of the temporal bone, the great wing of the sphenoid, including the foramen ovale and the foramen spinosum, the body of the sphenoid bone, and the edge of the basilar process would be attacked. This corresponds to the common site of origin on the lateral wall of the nasopharynx, which Trotter[18] [19] described, and constitutes about 80% of the cases in which the base of the skull is invaded. The third type of invasion is a mesial destruction of the body of the sphenoid bone, which includes the sella, posterior clinoid processes, and sometimes the clivus further back as well. This situation is likely to produce ocular symptoms without affection of the 5th nerve. Pulmonary metastases were found in 3 cases only.

It will be inferred from this condensed review of an elaborate and detailed investigation that early diagnosis of tumours of the nasopharynx is not the rule, and that when diagnosis is made invasion of the base of the skull, the surrounding tissues, and the lymphatic glands in the neck has already often occurred. The success of radiotherapy must be due to the anaplastic lowly differentiated character of many of the tumours, which are very sensitive to radiation. A collection of 540 cases of nasopharyngeal tumour reported by eight different writers showed that 62 patients were free of symptoms for five years or more (that is, 11.4%), but only 10 of them had carcinoma; of the remaining 52, 24 had lymphosarcoma, 25 lympho-epithelioma, and 3 reticulum-celled sarcoma. The prospects of cure in this series were five times better for sarcoma than for carcinoma, as there were 270 of each in the whole series; and better results were obtained in the lympho-epitheliomas than in the lymphosarcomas.

There was much difference in the details of the methods used at the four different clinics, especially between the Swedish and Danish institutions. The periods of treatment varied from 24 to 72 days and the dosage from 3,300 *r* to 10,000 *r*. Radium and *x* rays were both employed. With the exclusion of patients treated after May, 1938, there were 266, of whom 117 had either ophthalmic or neurological symptoms. Altogether 59 of the 266 were found free of symptoms for five years or more—that is, 22.2%. Only 13 of the 117 patients with evidence of intracranial extension (that is, 11.1%) were free from symptoms for five years. Of the cases with glandular enlargement there were good results only in 18.8%, compared with 32.5% for cases without cervical enlargement. The poorest results were in the cases of squamous carcinoma: no patient with the epidermal type survived; of the patients with the other types of carcinoma 18 survived. There were 38 survivors among the patients with sarcoma; of these 32 had reticulum-celled sarcoma, 4 lymphosarcoma, and 2 plasmocytoma. It was found that many of the patients became symptom-free as an immediate effect of the treatment (327—or 72.1% of the 454), but in 167 there was a recurrence. There were, however, among the patients free from symptoms for four years 2 with epidermal squamous carcinoma. The best results have been obtained, alike in males and females, in patients under 40. Most recurrences are during the first year after treatment, but 9 cases of recurrence have been observed after more than five years.

WOMEN ON WAR WORK

In a study[1] of women on war work in four factories Dr. S. Wyatt and his five assistants describe the continuation of an earlier statistical study of sickness absence among women in industry (Report No. 86 of Industrial Health Research Board). In that report it was shown that a comparatively small proportion of the women were responsible for the greater part of the time lost through sickness, so a detailed comparison was now made between groups of women who had the most sickness absence and those with the least. In all, 250 women in each of these classes were interviewed, the interviews lasting from 30 to 60 minutes. Detailed information was sought about their reactions to numerous conditions inside the factory, such as physical environment, personal relations, and hours of work, and to various factors outside the factory, such as transport and home life. As a rule the two classes of workers reacted in more or less the same way, but in a few respects they showed wide differences. Rather over half of all the women were satisfied with the atmospheric conditions of the factories, and nearly all of them were satisfied with the lighting. No less than 94% of them appeared to be satisfied with their fellow-workers, but only two-thirds were satisfied with their supervisors. Some of the workers were on day rates of payment and others on piece rates, and, rather unexpectedly, substantially more of the former than of the latter were satisfied with their wages. Many of the piece workers did not like the rush of work, and they were afraid that their piece rate might be cut, while the day workers, though they earned less, had the satisfaction of knowing that their wages were independent of the output. Various systems of shift work were in operation at the factories, half of all the workers being on the three-shift system, a fifth on two shifts, and the remainder on one shift. On the three-shift system they all changed over every week between morning, afternoon, and night work, and they put in, on an average, 45 hours of work a week. The arrangement of hours varied much in the different factories, but the women did not complain, over 90% being satisfied. The morning shift was by far the most popular, because it provided opportunity for recreation and amusement in the late afternoon and evening. The night shift was the least popular, but night work (under three-shift and two-shift systems) was not so unpopular as might have been expected. Only 36% of all the women definitely disliked it, chiefly because they could not sleep well in the daytime. Two-fifths of the women got less than 6 hours in bed, and only 14% got over 8 hours. Appetite was liable to be upset, leading to digestive troubles. No less than 55% of the women showing most sickness absence said that their health had been impaired by factory work, as contrasted with 37% of the women showing least sickness absence, and 15% of the former said that their work induced excessive fatigue, as contrasted with 8% of the latter.

[1] Wyatt, S., and assistants: *A Study of Women on War Work in Four Factories*. Report No. 88 of Indust. Hlth. Res. Bd., 1945, H.M. Stationery Office, price 9d.

As regards duties outside the factory, the married women naturally suffered more than the single women, 46% of them having to do all their housework and shopping, as contrasted with 12% of the single women. Again, 66% of the married women, but only 34% of the single women, suffered from home difficulties in general, including the care of children, the women who had most sickness absence suffering much more than the others.

Simultaneously with the publication of Report No. 88, the Industrial Health Research Board issued a popular illustrated pamphlet[2] embodying a summary of its contents and of Report No. 86. This ought to be of great value in propagating information about the health of women in factories, and in indicating the need for further research.

CHEMOTHERAPY OF FUNGOUS DISEASES

The chemotherapy of fungous diseases is still in its infancy, but research is being devoted, especially in the United States, to the discovery of new fungicidal drugs. Keeney, Ajello, and Lankford[3] [4] [5] report the results of three separate series of experiments *in vitro* to determine the fungistatic value of (*a*) sodium propionate and salts of other fatty acids of the same series, (*b*) drugs of the sulphonamide group, and (*c*) penicillin. Cultures of the more important pathogenic fungi causing superficial or deep mycoses were used in the tests. Sodium propionate, which is used in the confectionery trade to prevent mould growth in dough and cake mixtures, was found to be fungistatic to many pathogenic fungi. Salts of other fatty acids of this series—valeric, caproic, caprylic, capric, and undecylenic acids—were also fungistatic, and this property appeared to increase with the length of the carbon chain of the fatty acid, so that sodium caprate and sodium undecylenate were more fungistatic than the others. Tests showed that fungicidal power also increased with the length of the carbon chain of the acid, but the lowest member of the series used, sodium propionate, was not fungicidal although fungistatic. All salts in the series were in some degree toxic to white mice; and the greater the fungistatic power the greater the toxicity; therefore the therapeutic value of these salts for the deep mycoses cannot be determined until their toxicity has been more fully investigated. Of their usefulness in the treatment of the epiphytic diseases, especially ringworm of the feet, there is no doubt, the most efficient being sodium propionate and sodium undecylenate, for although the former is not fungicidal it is, in greater measure than the undecylenate, antibacterial against *Staph. aureus* and Group A haemolytic streptococci, occasional secondary invaders complicating foot ringworm.

The results of *in vitro* tests with the sulphonamide drugs in the treatment of superficial or deep mycoses were not encouraging, but evidence justified a clinical trial of sodium sulphamerazine in chromomycosis and of sodium sulphathiazole in histoplasmosis. In spite of the favourable clinical results reported by other writers, Keeney and his colleagues were not impressed by the effect of sulphonamides on actinomycosis. Penicillin was found to have no inhibitory effect on the growth of any of the pathogenic fungi investigated except *Actinomyces bovis*; in fact, in many instances it stimulated the growth of a fungus, and therefore might prove harmful in clinical use. Although, *in vitro*, penicillin is lethal to *Actinomyces bovis*, and in spite of recent reports of impressive cures from its use in actinomycosis caused by both *A. bovis* and the aerobic types of *Actinomyces*, Keeney and his colleagues conclude that these reports "do not warrant unrestricted enthusiasm for this mode of therapy."

In the treatment of ringworm, especially the form known as "athlete's foot," sodium propionate and sodium undecylenate are employed in ointments with the following formulae: Propionate-propionic acid ointment: sodium propionate 16.4, propionic acid 3.6, propylene glycol 5, N-propyl alcohol 10, zinc stearate 5, "carbowax (4,000)" 35, water sufficient to make 100. Undecylenate-undecylenic acid ointment: undecylenic acid 10, triethanolamine 6, propylene glycol 14, "carbowax (1,500)" 10, "carbowax (4,000)" 40, water sufficient to make 100. The water-soluble carbowax base, which aids the penetration of the antifungal substance, is to be preferred to a petrolatum base.

Keeney and his colleagues[6] found the above two ointments to be superior to Whitfield's ointment and to 10% ammoniated mercury ointment in their fungistatic action on cultures of a selected strain of *Trichophyton mentagrophytes* (a common cause of athlete's foot); the propionate ointment was superior to the other three in antibacterial action against *Staph. aureus* and a Group A haemolytic streptococcus. The results of clinical tests on cases of athlete's foot, although not conclusive, suggested that the propionate ointment was probably more effective than the undecylenate; both, however, fulfil the requirements of a good therapeutic agent for foot ringworm in being fungistatic or fungicidal and antibacterial; possessing the power of penetration; and being free from irritant or sensitizing properties even when used over long periods.

CATALOGUE OF MEDICAL FILMS

The Scientific Film Association, as our readers are well aware, was formed in 1943 to act as a centre for the collection, collation, and distribution of scientific films and, by promoting their use, to achieve a wide understanding and appreciation of scientific methods and outlook. It is governed by a council, which has set up special committees to advise and help it in specialized fields. The Medical Standing Committee, which was inaugurated in July, 1944, under the chairmanship of Mr. McAdam Eccles, soon found that its services were in great demand, and an executive committee was formed in October, 1944, which has met twice monthly since then. The preparation of a catalogue of medical films, which is the subject of a letter in our correspondence columns this week, is a work of outstanding importance, for when completed it will list all the medical films known to exist in Great Britain, and will record under each title a summary of content and a critical appraisal prepared by a panel of experts, as well as the usual details of availability and length. As new films are completed details will be issued in supplements, and notes will be given of those withdrawn from circulation. A comprehensive recording system is used, which other countries, including some members of the British Commonwealth, now have under consideration. The catalogue will probably be published part by part, and first instalments may be expected towards the end of this year. During the second series of medical film programmes presented by the Medical Committee of the Association at the Royal Society of Medicine, 18 films, covering a wide range of subjects and methods of presentation, were screened to audiences averaging over 200. A new selection is being planned for the autumn which will be devoted to a number of the more specialized subjects. In addition to this work on films which already exist, the committee is drawing up, for publication this autumn, a memorandum on films which need to be made immediately for use in teaching. The honorary secretary is Dr. Brian Stanford, and inquiries about its general activities should be sent to him at the Scientific Film Association's address: c/o Royal Photographic Society, 16 Princes Gate, London, S.W.7.

FALSE POSITIVE TESTS FOR SYPHILIS IN MALARIA

For many years it was thought that malarial infection might cause false positive reactions for syphilis, but it is only recently that the percentage of these was known to be considerable. Immediately after the last war a series of tests was carried out at the Military Hospital, Rochester Row, and though several cases of malaria gave positive reactions, all, or nearly all, were proved to have syphilis as well. In 1920 Iyengar[1] found no positives in 98 cases; in 1921 Pratt Johnson[2] and in 1924 Altounyan[3] stated that malaria had no appreciable effect on the Wassermann reaction, and another observer, after carrying out several hundred thousand Wassermann and Kahn tests in India and in the United Kingdom, always taught until recently that malaria should not be the cause of false positive reactions in a well-balanced test. In the last few years, however, more and more false positive reactions have been reported, and it may well be that this is due, in part at all events, to the increasing sensitivity of the various serum tests employed. Cumming and his colleagues[4] recorded percentages of from 8.6 to 20.6 in a series of tests carried out by thirteen pathologists, while Kitchen and his colleagues,[5] treating with malaria 25 non-syphilitic patients with functional psychoses, obtained a positive reaction with a complement-fixation or flocculation test at some stage in every case. There are many more examples in recent literature, and it may be accepted that malaria can give rise to false positive reactions. It is not known what is the frequency of these, at what stage (before, during, or after the fever) they are most common, or how long they may persist. It seems probable, however, that false positive reactions tend to disappear within three, and usually within two, months of an attack.

How, therefore, should one interpret a positive serum test for syphilis in a patient known to have, or suspected of having, malaria? The Kahn "verification test,"[6] whereby true reactions may be distinguished from false by incubation at 37° C. and 1° C., when true reactions will occur with the former and false with the latter, may be helpful on occasions, but is not altogether reliable. Cox and Durant[7] state that if a series of Wassermann and Kline tests is carried out, and if there are discrepancies in the results and no history of syphilis, syphilis may be excluded. Brown and his colleagues[8] recommend treating the serum to be tested with N/3 sodium hydroxide before inactivation, and assert that by this method non-specific reagin is destroyed or removed. Rosenberg[9], claims to be able to distinguish between positive reactions due to malaria and syphilis respectively by the "pattern of positivity," employing six tests—Kahn, Kolmer, Mazzini, Eagle, Hinton, and Kline. Of these the Hinton test gave the lowest number of false reactions. There is also the fact that positive reactions due to malaria rarely persist beyond six weeks. Potter and his colleagues[10] found twelve positive Wassermann or Kahn reactions in 100 cases of malaria; but all these reverted to negative within 30 days, with an average of 12 days, and many in 7 days or less; in each the Wassermann reaction of the cerebrospinal fluid was negative. Rosenberg[11] states that if 0.35 c.cm. of saturated ammonium sulphate is added to 1 c.cm. of inactivated patient's serum syphilis reagin is precipitated but malarial antibody is not, and that the two can be distinguished by this means.

The value of few of the above methods has been confirmed, and it will be wise for the present to be sceptical of any serological method said to distinguish between true and false reactions. Where a false positive reaction occurs in a patient who has no history or clinical signs of syphilis, and more particularly if he is suffering, or has recently suffered, from malaria, the test or tests should be repeated. A reaction due to malaria is generally weak, tends to become weaker with lapse of time (here quantitative tests are useful), and invariably reverts to negative sooner or later—almost always within three months. Syphilis should never be diagnosed merely on the strength of a single positive test; such a procedure is unscientific, and unfair to the patient.

ADVERTISEMENTS OF PERMANENT APPOINTMENTS

The Council of the B.M.A. has decided that advertisements of permanent medical appointments which do not invite applications from practitioners serving in H.M. Forces and allow at least four months for the receipt of applications should be refused publication in the *British Medical Journal*. In the event of an employing authority declining to bring an advertisement into conformity with the policy of the Association the appointment in question will be included in the "Important Notice" in the *Journal*. If an advertisement of a permanent medical appointment the wording of which conflicts with the policy of the Association is published in a newspaper, an announcement in the form of the "Important Notice" will be inserted in the same newspaper. The policy of the Association in regard to advertisements of permanent medical appointments at the present time, as recently explained to hospital authorities, has been communicated to employing authorities generally.

The King has approved the appointment of Sir Lionel Whitby to the vacant post of Regius Professor of Physic at the University of Cambridge.

MEDICAL PHOTOGRAPHY IN HOSPITAL

[From a Correspondent]

Research into methods of hospital photography in this country is sorely needed. Excellent work has been done under poor conditions, but how much more efficiently it can be turned out from well-planned, well-equipped laboratories is shown by the excellent illustrations reaching us from America. It is no good British doctors demanding pictures comparable with these, however, unless the same facilities are available.

The first thing needed for a medical photography department is a complete system of air conditioning, not only to draw out dust, soot, fumes, and bad air, but also to maintain the temperature at a certain level. All normal processing has to be done within a limited range of temperature; above this level gelatin melts, films frill, and other things go wrong, and below it some chemicals refuse to work at the same speed and so interfere with the balance of densities. Next a mobile unit (camera and lights) and a miniature camera with synchronized flash should always be in readiness for work in the theatre, wards, and departments. Electric fittings all over the hospital should be of one pattern so that mobile units can be plugged in anywhere, and lighting units should be so designed that one does not continually fall over leads and tripods.

Scope of Hospital Photography

For too long hospital photography has been done by radiographers or not at all. Radiographers are trained in photography relating to their own job—the interior of the body—and the technique is very different from that for the exterior and for the numerous jobs of a clinical photographer. Because of this and because more and more work is falling on both departments, the photographic department should be staffed by experts and possess suitable apparatus. Photographers carry on the good work of the radiographers by reproducing from the radiographs small-sized duplicate films or lantern slides for teaching and prints for publication. But this is only one of the jobs falling to them. In the clinical work of the hospital they may be called upon for full-length photographs of figures or limbs to show position; "close-ups" for detail of lesions, ulcers, etc.; photographs of cavities, swellings, skin reactions, etc.; and, for the pathological department, of specimens and also photomicrographs. The demands for photomicrography and cine-photography are increasing, and the value of colour in diagnosis is being more appreciated. All departments want photographs of apparatus, surgical instruments and appliances, and copies of drawings, charts, photographs, etc.

Further photographs provide permanent records of the exact clinical condition at the moment of taking, and when a series are made over a period of time the doctor can see immediately the changes that have taken place. Such photographs filed with a patient's history are time-saving; they are also helpful in planning treatment, and invaluable for purposes of comparison in investigations. A photograph in a published paper will show at once what might otherwise take pages of reading matter to explain.

Scheme for a Hospital Department

The following is a brief outline of a scheme for a hospital photography department. It might be possible for one hospital in ten to build such a department, and by catering for the other nine to become, eventually, self-supporting.

Staff.—Director (fully qualified medical photographer); secretary to the director; three senior photographers (1 colour); three junior photographers (1 colour); clerk to the photographers; four first-year students; four second-year students; and a cleaner-porter. Salaries as fixed by the Institute of British Photographers.

Duties.—One senior and one junior photographer, known as operators, are responsible for all photographs (except those taken in colour) taken in the studio, wards, theatre, various departments, and other hospitals, and must, when the negatives are dry, deliver them with full written instructions to the printer. One senior and one junior photographer, as printers and finishers, are responsible for all work done in the processing laboratories and finishing room, except photographs in colour. One senior and one junior photographer are responsible for all colour work. The clerk's job is to make all appointments, see that patients keep them, and that the patients' instruction cards and copies of earlier photographs are delivered to the operator in good time. The clerk is also responsible for seeing that all records are filed or delivered to the departments, or, where necessary, to other hospitals.

Students.—The students, who pay an entrance fee, are given every possible help by lectures, demonstrations, and practical work in passing examinations which will qualify them for membership of the Institute of British Photographers. The advantages of the student system in hospital are the contact with doctors and nurses and the experience in handling patients. There are three qualifying examinations, and any student passing the second before the training time is up may, if he wishes, be taken on as assistant photographer and be paid a suitable salary, or he may leave to take up a position elsewhere; otherwise the course is for two years. In their first year students have a general training in hospital photography; in the second they have a choice of work and may, if they wish, concentrate on a particular branch, such as colour photography or photomicrography, etc. The subjects of lectures include optics, photographic chemistry, anatomy, colour, and general photography.

Institute of Medical Photography

An Institute of Medical Photography is urgently needed. This would be a training centre where every branch of photography would be studied and undertaken for doctors, hospitals, etc., and where patients and work would be sent. It would supply staff with mobile units wherever they were needed, also trained staff for photographic departments. It would have a special department, with membership on camera club lines, where members could meet and do their own work if they wished. Meetings would be held there providing an opportunity for photographers to meet the instrument maker, the electrician, and the mathematician and discuss the construction of suitable apparatus, instruments, and equipment. Finally, the work done at this institute would be so good that it would achieve international repute, and people from all parts of the world would come to study its methods.

MRS. BEETON AT THE HOSPITAL

Two or three years ago the King Edward's Hospital Fund for London published a memorandum on hospital meals. It was welcomed because it opened up the prospect of improvement in an important sphere of hospital work which, in some institutions, was well below standard. But it also showed how many problems there are in hospital catering, and the Fund set up a committee on hospital diet, under the chairmanship of Sir Jack Drummond, to examine them. This committee has prepared a second memorandum, based on recent experiences and observations, with the object of helping those hospital authorities who are making an effort to bring their catering arrangements up to a more satisfactory level.* The organization of the catering department in a hospital is considered at length. It is urged that catering should be regarded as a single important function of a hospital, and one which requires an experienced catering officer together with a competent staff. The most suitable person as catering officer would be a dietitian whose knowledge of nutrition and dietetics is supplemented by an adequate experience of large-scale catering, but such a person is not always easy to find, and, failing him or her, a catering officer should be appointed whose knowledge and experience have been gained in the hotel or catering trade. Such an officer should be responsible for the buying of food, control of stores, planning of menus, cooking, and service, and should report to the chief executive officer of the hosptial and through him to the governing body, or directly through a Diet and Catering Committee, formed after the fashion of the medical committee, of predominantly technical and professional composition.

The memorandum discusses the staffing of kitchens, and hints that the monotony of many hospital menus is a reflection not of restricted wartime rations but of the employment of third-rate cooks, unimaginative menu planning, and, sometimes, financial stringency. One section of this little work is devoted to the value of salads and to the proper cooking of vegetables. The desirability of vegetable salads is stressed, and a number of recipes are given. The outline menus may appear almost fantastic to those who have had experience of the unexciting character of meals in some institutions. Here is a suggested menu for a full diet which can be provided under present conditions:

---

* King Edward's Hospital Fund for London. Second Memorandum on Hospital Diet. 9d. net, post free.

When Called.—Cup of tea.

Breakfast.—Porridge or cereal; breakfast dish (11 choices in a separate list); bread-and-butter/margarine; tea, coffee; marmalade once or twice a week; occasionally fresh fruit, hot rolls.

Mid-morning.—Milk; meat or yeast extract; fruit drink; cocoa.

Dinner.—Meat (occasionally fish) (10 kinds of meat or fish, each cooked and served in various forms); potatoes; cooked vegetables or salad; sweets: pudding and milk pudding as alternative. (63 choices of sweets in separate list.)

Tea.—Bread-and-butter/margarine; jam, honey, syrup, or paste or salad, cake, scones, or buns; tea.

Supper.—Cooked dish (separate list of large number of alternatives, hot or cold); sweet; bread-and-butter/margarine; milk, cocoa, etc.

This excellent pamphlet also contains examples of recipes of 13 savoury dishes, 8 sweets, and 7 pastries and sauces, each for 50 persons. It might be commended not only to hospitals and nursing homes but to canteens, hostels, and institutions of all sorts where meals are served, while most hotels might profit from a glance at it.

OCCUPATIONAL RESETTLEMENT OF THE DISABLED

CRITICISMS OF GOVERNMENT SCHEME

P E P (Political and Economic Planning) has issued a broadsheet (*Planning*, No. 238) on the Government's plans for rehabilitation and resettlement of ex-Service men. A consideration which is perhaps not appreciated as it should be is that only one-quarter of all disablement is due to direct physical injury like amputations; three-quarters is due to organic disease or to neurosis. It is easier in general for the physically injured man, after an initial period of adjustment, to settle down to normal life and work than it is for one who is suffering from chronic disease or from some psychological trauma. The problem of disablement, says P E P, will get out of focus if it is considered as wholly or mainly a question of physical injury.

The Pivot of the Scheme

There are signs, says this broadsheet, that the Government's resettlement arrangements, well thought out on paper, are yielding too high a proportion of failures. The Ministries concerned have done their best, within the limits of available personnel, to produce efficient machinery for the re-establishment of normal life, but in practice something has gone wrong. Examples are given of cases in which a man was offered or directed to unsuitable work by the disablement rehabilitation officer, and only through a welfare follow-up was the mistake eventually recognized and the man placed in a satisfactory job. The disablement rehabilitation officer is the pivot on which the Government scheme turns, but the first contact with this representative of the Ministry of Labour comes too late. The D.R.O. should be introduced at a much earlier stage of a man's stay in hospital; he should be a familiar figure about the wards, and should have more opportunity to talk to patients and thus be made better able to appraise their capabilities.

It is also said that the D.R.O. is insufficiently trained, and has inadequate knowledge of industrial work, and little understanding of the background of the men he interviews; that his approach is too casual; that he lacks initiative; that he has not had the right type of education or experience; and that he has not the skill to overcome suspicion or shyness and is not fully appreciative of the difficulties arising from medical and nursing conditions. These men are selected from the staffs of employment exchanges, where they have acquired little internal knowledge of industrial conditions and none at all of social welfare. Some of them, no doubt, are conscientious and kindly, but too many are temperamentally unsuited to the needs of the job. Many are of the same age as the young ex-Service men they interview, and that in itself creates a barrier.

P E P urges the widening of the field of recruitment of these men. Selected ex-Service men, after a certain amount of training, should be taken, also welfare workers who have been employed in dealing with the personal difficulties of working people in their social setting, and labour officers of the Ministry of Supply who, from their experience in ordnance factories, combine some understanding of industrial matters with the knack of assessing a man's capability for a particular job.

Abolition of Pensions Ministry Suggested

Another suggestion of the broadsheet is that carefully selected field officers should be appointed to Service hospitals and E.M.S. units handling long-term cases—men who would live among the patients and really get to know them and build up the necessary confidence; and the work of these officers, like that of the hospital almoners, should be followed up by social welfare workers who would regularly visit the disabled man after he had left the hospital. It is also proposed that the Ministry of Pensions should be abolished, its medical services transferred to the Ministry of Health, and its income, maintenance, and welfare functions to the Ministry of National Insurance. One Department less would mean much less chance of interdepartmental friction. There would still be three Ministries primarily concerned with the disabled ex-Service man—the Ministry of Health for medical care, the Ministry of Labour for training and resettlement, and the Ministry of National Insurance for financial support and general welfare. It is therefore suggested that these three Ministries, possibly in conjunction with the Ministry of Education and the Services Departments, should maintain an interdepartmental council to concert joint action for rehabilitation, training, and resettlement of all disabled persons, with similar joint machinery established locally, or a National Rehabilitation and Resettlement Board might be set up to exercise delegated powers, with the disablement rehabilitation officers and social workers attached to its local or regional agencies.

There is already in existence a Disabled Persons (Employment) Corporation, designed to meet the needs of those whose disability makes it impossible for them to work on equal terms with the able-bodied. Nothing can be said in criticism of it, for it has not got much further than registration as a public company, but its title seems unfortunate. "Strengthen me by sympathizing with my strength, not my weakness; find out what I can do and let me do it, and forget what I cannot do and let me forget it," was the wise slogan given by Mr. H. E. Griffiths at a recent conference on occupational readjustment. Canada has an organization, Vetcraft Industries, for veterans of the 1914–18 war. It is supported by the Government, and has Government Departments as its sole customers. From small beginnings the organization now supplies a wide range of products. This Canadian example may give an idea of how such a project should be developed.

A final suggestion is that early consideration should be given to the taking over by industrial concerns, with Government co-operation, of disused Service installations and converting them into industrial colonies for the provision of jobs and homes for disabled men, though at the same time it is pointed out that segregation of the disabled is in general undesirable and should be avoided except where there is no other choice.

The thirtieth annual report of the Committee of Management of the Royal Victoria Hospital Tuberculosis Trust has been published in Edinburgh. Several pages are devoted to the prevalence of bovine tuberculosis and existing methods of control. After reviewing the facts the conclusion is clearly stated that at the present time the public should safeguard themselves by using either one of the grades of milk guaranteed to be produced free from tuberculosis infection or the pasteurized variety. It is of the utmost importance that any other variety of milk should be brought to boiling-point before use, particularly if it is for consumption by young children. The committee feels strongly that nothing short of the complete elimination of infected bovine animals must be the ultimate aim. Until this is attained there will remain a real menace to life and health. This question therefore should have a prominent place in post-war health planning. The cost of such an effort measured against the social and economic advantage would be relatively small.

Correspondence

Small Hospitals: Efficiency and Economy

SIR,—"Hospital Survey: The Hospital Services of London and the Surrounding Area," that formidable-looking Blue Book, has by now probably been seen by all those interested in hospital work, whether layman or doctor, and it will be agreed by all that Drs. Gray and Topping have carried out their task in an impressively comprehensive manner and with an efficiency which could not be excelled. The statistical tables which form the largest portion of the book are of the greatest value to hospital organizers, and to my knowledge are in constant consultative use in most hospitals. We must, all, therefore, be appreciatively grateful for the tremendous labour which the authors have put into such a Herculean work.

But, having paid tribute to "Hospital Survey," we should not let our appreciation blind us to the fact that, like many other such reports, it was produced under certain conditions and auspices which have an influence upon its recommendations. I refer to the knowledge that the survey was undertaken at the instigation of the Minister of Health in 1941 and that there must of necessity have been terms of reference. What these terms were is not quite certain; but, whether definitely stated or merely implied, it is clear from reading the report that they involved the idea of discovery whether the hospital services could be more *efficiently* and *economically* (not only in the financial sense) run. If this was indeed the real state of affairs it must be constantly borne in mind when considering the report that it had a restricted aim in view, and all its recommendations should be seen in the light of those restrictions. In other words, the report now becomes the opinion of two well-informed minds upon the possible change which would make for greater *efficiency* and *economy* of working. Such a viewpoint immediately changes one's reactions to the Blue Book, for when I regard the report as a complete survey of hospital activities I cannot escape the conviction that it is a completely soulless document; but if I think of it as an essay upon the possible changes which might lead to greater *efficiency* and *economy* then the book stands in a different category, for I am now at liberty to ask what efficiency in medical work means, and whether it is to be the be-all and end-all of medical ambition. Efficiency is difficult to define; who knows what efficiency in its medical application is? Medicine changes so rapidly that what is worshipped as efficiency to-day becomes a clay-footed idol to-morrow. When our dramatic critics say that Miss A.'s acting was efficient, what do we think? Were Turner's paintings, Shakespeare's plays, efficient? Surely we have to think of more in medicine than efficiency. Supposing the Home Secretary asked for a "Family Survey" it would be possible for an assiduous worker to produce a report the logic of which was beyond challenge, but it would of necessity have to contain such statements as: "We found that the one-child family is inefficient and uneconomic, and so we suggest that all children from such families be transferred to the larger families of four or more children." Irrefutable logic, once we accept that efficiency and economy of effort are the final aims.

This brings me to the main point of this letter, for I notice that it is proposed to turn many of the small hospitals into mere annexes of the larger, for the reception of convalescent patients and the like. The basis for this suggestion is that the small hospital is inefficient and uneconomic. I cannot agree for two reasons: in the first place, as I have tried to explain, I do not think that in matters of medical treatment we should raise efficiency to a god-like status; in the second place I do not believe that most of these small hospitals are inefficient when judged by the only criterion that matters—namely, results. It is my privilege to work in both classes of hospital, from over 1,000 beds on the one hand to 50 on the other, and I find that my results are as good in the one as in the other—this for major surgery. I am, of course, not ignorant of the fact that there are certain very highly specialized types of treatment which the small hospital is not equipped to undertake. Cases requiring such treatment, however, make up a very small percentage of the whole and can be dealt with by affiliation with a large institution.

The intangible factors connected with the small hospital—local pride and faith in the institution and so on—cannot unfortunately be estimated by statistical tables suitable for reproduction in "Hospital Survey," but they are in my opinion more important to the well-being and happiness of the patient than a lot of efficiency, which in any case is not lacking.

What the legal implications of the recommended changes are I have no means of knowing, but it is certain that in many instances the money for starting and running such small hospitals has been given specifically because they are what they are. I suppose an omnipotent Parliament can change any law, good or bad, so that this difficulty may not require consideration.

Since writing the above I have had an opportunity of reading the report of the King's Fund upon the same subject, and I note with pleasure that, with certain safeguards, its recommendations are favourable to the retention of the small and cottage hospitals, and that the authors display a keen appreciation of the human as well as the humane side of hospital work.
—I am, etc.,

NORMAN C. LAKE.

Safe Milk

SIR,—This is a most important subject and affects very closely the health of our children. The American viewpoint on our milk is interesting and should be stimulating. The universally suggested remedy is pasteurization, which is, of course, very sound; incidentally it is also very expensive and adds to the retail price of the milk. Surely every household could be taught to sterilize its milk; a temperature of 60° C. would ensure against most infections, and boiling against all. A double pan would guard against overheating and so mitigate against alteration of the taste, except to a very limited extent, if that is desirable. This method is much too simple for modern ideas; everything must be complicated and expensive to have any value.

What is difficult to understand is why dried milk (superheated) is considered suitable for children but boiled milk is not. Boiling does not affect the nutritional value of the milk; the destroyed vitamins are easily replaced. It is my practice always to encourage parents to rear their children on boiled milk if breast-feeding is not possible. Those so persuaded have had no reason for regret. In one particular case people came to see the fine healthy baby reared on ordinary cow's milk. This is characteristic of the artificial mentality produced by advertisements, aided and abetted by local authority clinics all over the country, which sell their favourite brand of dried milk at 1s. 6d. instead of the ordinary retail price of 7s. 6d., possibly as a bribe (part at least of the difference in price is made up by the ratepayers). Parents are not very helpful because, as the children grow older, they are told that boiled milk is horrid and so are prejudiced in favour of unboiled milk. If not so prejudiced the children would probably acquire a taste favourable to the heated variety.

Milk is the only important food that is taken in the raw state and by the most sensitive of our people, whether children, aged, or ill, yet very little is done about it of a really practical character. I would not exempt T.T. or accredited (horrid word) milk from the blessing of boiling or its equivalent. Most working-class homes are visited by swarms of officials of all kinds who could be used to influence parents in favour of heated milk. I have repeatedly brought this viewpoint to the notice of the local health committee, but got no encouragement. If the milk was as sterile as the official mind then all would be well.—I am, etc.,

Birkenhead. D. J. GAIR JOHNSTON.

Famine Oedema: A Clinical Description

SIR,—Famine oedema was frequently seen in refugees from enemy-occupied islands in the Dodecanese. All the patients were adults, mostly over 30, and all had suffered from starvation. They had lived on green vegetables for at least three months, and the majority had actually eaten grass. Potatoes, bread, meat, and fish were available to some of the patients, but only on extremely rare occasions. Such bread as was available was black and of very poor quality.

The onset of symptoms was usually sudden, with swelling of thighs or feet, and accompanied by pain. Pain may precede the actual oedema. Unaccustomed exercise or a sudden lowering of the patient's general condition by some cause such as infective diarrhoea may precipitate the onset. On recovery a relapse is easily caused by the same factors. Swelling of the feet is the usual presenting symptom, but a large number of patients complained of "thickening and hardening" of the thighs, which pitted on pressure. Later on, in twenty-four-hours' time, the swelling of the feet was evident in these cases and the oedema of thighs had disappeared. Swelling of the hands was rarer. Pain is a frequent symptom and prevents sleep at night; tenderness on pressure is almost a constant feature. The patients all complain of weakness and debility. No skin changes were seen. In all cases the heart was normal, the urine was clear, and no history of rheumatism, scarlet fever, or nephritis was given.

Treatment, such as could be given under extremely primitive conditions, consisted of 2 ounces of canned milk, 2 tablets of vitamin C, and 3 tablets of ferrous sulphate daily, in addition to the usual refugee ration. Rest and sunbathing were advocated.

The oedema lasted a long time. The quickest recovery time was one month, and many cases show only slight improvement after three months of improved conditions and "treatment."

A lack of proteins in the diet, with consequent lowering of blood proteins, seems to be the cause of the condition. The position of the oedema appears to be due entirely to posture. This was very noticeable in patients with swelling of the thighs who had been sitting for some time, the backs of the thighs being more oedematous than the fronts. A good mixed diet is needed to dispel the symptoms, but this was not available on the island where the cases were received and seen.

I should like to thank Lieut.-Col. N. S. Turnbull, P.M.O. of the Dodecanese, for permission to publish this record.—I am, etc.,

Friends Ambulance Unit, M.E.F. RAYMOND MILLS.

Trilene in Midwifery

SIR,—I pointed out the possible dangers of trilene in midwifery in the *British Journal of Anaesthesia* for July, 1944. I have now administered almost 1,000 trilene anaesthetics and recorded my experiences with the first 500. Consideration of these results led me to reserve trilene for healthy subjects in whom a high degree of relaxation is not required and where the expected duration of anaesthesia is short—i.e., up to 10 minutes. I have found the complications of longer anaesthesia do not occur in these short administrations.

When planning anaesthesia in midwifery it is necessary to appreciate that the terminal stage of labour may not go according to plan, and a patient intending to be confined at home may have to be sent into hospital during labour. Trilene may have provided efficient analgesia during the early stages of labour, but may not be a satisfactory anaesthetic for final delivery, particularly if operative intervention is necessary. The lithotomy position is difficult to maintain unless the patient has been heavily premedicated, tachypnoea may be troublesome, and abdominal relaxation is not sufficient to provide good working conditions for the surgeon if Caesarean section is necessary.

In my series of cases when anaesthesia lasted longer than a few minutes, 80% showed an alteration in pulse rate with about 16% of pulse irregularities. In view of these findings, if operative intervention becomes necessary it is advisable to resort to some form of anaesthesia other than trilene. When using a standard Boyle machine without a CO_2 absorber, my own experience in changing from nitrous oxide–oxygen–trilene to nitrous oxide–oxygen–ether was that after a few minutes there was always a rise in systolic blood pressure and pulse pressure with a high incidence of bleeding during operation. These findings were also present when the patient had had only a few breaths of trilene. In the control series of anaesthetics with open ether following nitrous oxide–oxygen–trilene these complications did not rise.

There has also been an alarming series of cranial-nerve palsies and some deaths when trilene has been used in the closed-circuit machine. (Cf. (1) Humphrey and McClelland, (2) Carden (*Journal*, March 4, 1944, pp. 315 and 319).) Some of these unfortunate complications occurred with anaesthetics where no trilene was used, but the same closed-circuit machine had been employed in which trilene had been used on a previous occasion without the soda-lime being changed. Apparently a mere trace of trilene in the machine is sufficient to react with the soda-lime, producing dichloracetylene, which is poisonous and is responsible for these serious complications.

When anaesthesia has to be deepened, if nitrous oxide–oxygen–ether is employed the patient who has received trilene analgesia has sufficient trilene in her exhalations for a consideraable time after the trilene analgesia has ceased to result in (1) serious haemorrhage if the standard Boyle machine is used, or (2) the production of toxic amounts of dichloracetylene if a closed-circuit machine is employed. The latter substance, in addition to being toxic to the patient then being anaesthetized, may contaminate the soda-lime container and thus affect subsequent patients similarly.

I am in full agreement with making every possible effort to give a woman in labour as much relief from pain as is compatible with her safety. Trilene analgesia is superior to nitrous oxide–air in the proportions provided by Minnitt's apparatus. I am at a loss, however, to understand why the analgesic properties of open ether have not received more attention. My own practice is to sprinkle a few drops of ether on to about eight layers of gauze stretched over a wire mask and put it over the patient's face as soon as a pain commences. The mask is removed at the termination of a pain. The patient thus remains co-operative and is relieved from pain. When ether is given in these analgesic doses atropine is not necessary. There is no coughing, salivation, or vomiting; two to three ounces of ether will provide a woman with two to three hours of analgesia during the later stages of labour. If nembutal is also given the patient usually sleeps between her pains. Full anaesthesia can be produced at any time without a change of anaesthetic. If oxygen is available it should be given under the mask, mother and baby both benefiting. The apparatus for ether anaesthesia is simple, safe, and portable, the chief contraindication to its use being an existing respiratory tract infection.

I would not venture to give trilene to patients suffering from cardiac complications or toxaemias of pregnancy. The point I wish to make in this letter is that caution should be exercised in the choice of anaesthetic following trilene analgesia or anaesthesia. Midwives cannot be expected to be specialist anaesthetists, and the responsibility of trilene in labour should not rest on the midwife.—I am, etc.,

Wakefield. EMILY E. JOHNSON.

Women in Labour

SIR,—The correspondence on women in labour leads, I think, to the following conclusions.

(1) That the vast majority of women desire more adequate relief of pain in labour than they obtain at present.

(2) That while every encouragement should be given to techniques —such as that of Dr. Dick Read—which endeavour to make labour relatively easy and painless by the careful application of physiological principles, it appears that most civilized women require some form of analgesia or anaesthesia.

(3) That in our present state of knowledge analgesic drugs for the first stage of labour and a simple inhalation technique for the second stage are the most efficient and generally applicable means of relieving pain.

(4) Several ingenious and very useful "self-help" analgesia machines are available, but they have the following disadvantages: (*a*) They do not give adequate relief to the "resistant" patient in the later stages of labour; this also applies to the very nervous type of woman who is too distraught to manage the machine herself. (*b*) They cannot be used for even simple operative midwifery, such as the application of "low forceps," so that usually in these cases a less desirable agent such as chloroform has to be used. (*c*) To maintain these machines in good working order the services of individuals skilled in the handling and maintenance of anaesthetic machines are required.

(5) With the best will in the world the present medical personnel could not devote the necessary time to give adequate anaesthesia to between 600,000 and 700,000 women a year.

What solution of these difficulties can we offer which can be put into operation reasonably soon? It can be said that the ideal analgesic drug for the first stage of labour remains to be discovered. However, from the big choice now in use most cases can be given considerable help during the first stage. A fair proportion of women can obtain good relief during the second stage by the use of "self-help" machines, provided these are kept in working order, and the woman trained in their use before labour begins.

There remains, however, a large proportion of women who will get adequate relief only during the last part of the second stage when given a well-conducted intermittent anaesthesia by a trained anaesthetist. The presence of such a person with a suitable machine is also required when that "little extra" is necessary for operative midwifery. If it is agreed that medical men cannot be spared for this work then a corps of trained medical auxiliary anaesthetists could be formed quite quickly. These auxiliary anaesthetists would work under the conditions set out by Dr. S. Wray (June 30, p. 924), and under the supervision of the medical man in charge of the case. They could work in maternity hospitals and with general practitioners in domestic midwifery. The general practitioner is very conscious of the fact that he cannot spend hours with his midwifery cases administering anaesthesia.

I feel that only on the above lines can the problem of the woman in labour be seriously tackled.—I am, etc.,

Harrogate. JAMES CAMPBELL.

SIR,—Dr. R. A. Hingson (Aug. 11, p. 196) quotes Grantly Dick Read's book *Revelation of Childbirth*, and says that he considers "caudal analgesia is a *natural* step [my italics] along the road towards the conquest of pain," presumably as one point at which the vicious circle described by Dr. Dick Read may be broken. I maintain that the ability to achieve natural childbirth *by her own efforts*, guided, where necessary, by the doctor, is of far greater help to a woman's sense of fulfilment than is the achievement of it by artificial methods. Surely the "leave-it-to-us, you-will-never-feel-any-pain" attitude towards an often tough but physiological high-spot of womanly experience is a very negative approach compared with the positive approach of the woman trained ante-natally in self-discipline and optimistic anticipation of a perfectly natural labour.

There is plenty of research in the easing of pain by various drug techniques (let us excel in their use and exhibit them freely when required), but far too little on the psychological, endocrine, and "even metaphysical"—to quote Dick Read again—aspects of the problem. A large part of the trouble is the antenatal time required to be given to the psychological approach in particular: it is so much easier to wait till labour starts and then administer drugs. But those who will make time will be amply rewarded, and I believe the reduction in inertias and post-partum haemorrhages especially would be quite remarkable. Incidentally, I think confinements should be conducted ideally in small institutional units; the large maternity hospital unit militates against personal self-confidence, except, of course, where frank abnormalities are anticipated.—I am, etc.,

Leeds. J. GORDON HUNT.

Rehabilitation of Fractured Limbs

SIR,—I am continually exercised in my mind as to the putting of fractures into plaster, leaving the soft tissues immobile for several weeks. Why can't the plasters be cut in two by Gigli thread saws and then secured by webbing straps? This was practised at Bart's 35 years ago. The soft parts can then be got at and kept alive as advocated by Meynell. The modern method seems to me to be distinctly retrograde and entails weeks of convalescing after union.—I am, etc.,

Stone, Staffordshire. R. MURRAY BARROW.

Accidental Infant Suffocation

SIR,—Dr. W. H. Davison (Aug. 25, p. 251) pleads for the routine performance of a post-mortem examination in a particular type of case—suspected asphyxia in infancy. Few will cavil at his thesis; many will look far beyond it and urge the more frequent use of this method of investigation over the whole field of medicine. Apart from the demands of scientific accuracy, morbid anatomy has still its conquests to make, and both are served by the widespread adoption of this procedure.

Further, the coroner for the City of Birmingham refers in passing to fatal infant asphyxia from inspiration of vomit, and finds that "the circumstances of how and when the child was fed did not seem to have any direct bearing on the death." My investigation of a larger series of cases does not confirm this; possibly because the technique of infant feeding varies in different parts of the country. I have frequently found this type of asphyxia directly associated with the common and dangerous practice of giving the infant, lying hungry in the cot, a full bottle of milk. Sometimes, if needs be, the bottle is supported on the pillow beside the infant. Rapid distension of the tiny stomach is followed by regurgitation into the pharynx, and a reflex inspiration results in the infant being "drowned" in its own vomit. The mechanism is precisely the same as that which occurs occasionally in cases of acute intestinal obstruction in adults during laparotomy, when the precaution of a preliminary washing out of the stomach or the insertion of a Ryle tube has not been observed. In either case mechanical obstruction by vomitus is the immediate cause of death—a fact which is readily established by post-mortem examination.—I am, etc.,

Coroner's Office, South-East Lancashire. F. G. RALPHS.

Chronic Regional Ileitis

SIR,—Chronic regional ileitis appears to be of sufficient rarity to warrant report of a case.

A married woman aged 30 had no previous history of any note until the onset of the present trouble four years ago. The first symptom noticed was pain, situated in the umbilical region, coming on in attacks, which occurred chiefly during the night, at intervals of several months. The abdomen felt to be swollen during the attacks, which were accompanied by a sensation of soreness in the right iliac fossa. Twelve months ago the attacks became more frequent, coming on every three months. The patient became pregnant in November, 1943, and was admitted to Reedyford Hospital in one of her attacks in April, 1944. This attack was accompanied by the vomiting of coffee-ground material, which relieved the pain; as had happened in the few attacks immediately preceding, the pain was in the umbilical region, but the tenderness was in the right iliac fossa, and the condition cleared up in two weeks. The diagnosis of subacute appendicitis was made, but in view of the pregnancy intervention was avoided. The patient gave birth to an imperfectly developed stillborn child in Colne Maternity Hospital in July, 1944, and had another of her usual "attacks" in September, 1944. Between the attacks, appetite, which was lost during them, was good. There was no constipation prior to July, 1944; but it was present from then on. There was no headache or loss of weight. The patient could tell the approach of an attack by "feeling she was filling up." The final attack started on Jan. 1, 1945, and there was soreness in the right iliac fossa till the patient was seen on Feb. 6. She had noticed some loss of weight in the previous two months, and had been more constipated. She complained of loss of appetite since the commencement of the attack, and felt swollen; she had also heard "rumbling noises in her stomach." This last attack was unaccompanied by vomiting. On examination the patient was found to be a well-nourished woman with no obvious loss of weight. The abdomen was not obviously swollen and no abnormal mass could be felt. The only definite sign of abnormality that could be elicited was tenderness on passing over McBurney's point. A provisional diagnosis of appendicitis (subacute) was made, and on Feb. 7 the patient was admitted to Reedyford Hospital.

At operation a typical salmon-pink sausage-shaped swelling, 10 in. long, extending proximally from about 2 in. from the ileo-caecal junction, was seen. The ileum was dilated to about twice its diameter for about 30 in. The mass at the centre appeared quite solid. Sixteen inches of the lower ileum, including the swelling, were excised and the apparently unaffected distal portion of the ileum was sutured end to end to the proximal part; the appendix was removed; a small drain was inserted; and apart from a small sinus which persisted for a fortnight progress was uneventful and the patient now appears quite well.

Radiologist's Report.—"Mass of granulation tissue filling lumen of bowels to the extent of apparently complete obstruction."

F. G. Ralph (*Brit. J. Surg.*, 1938, **25**, 524) comes to the conclusion that "the inflammatory mass is the response of the tissues to a slow infection of low virulence." However that may be, the disease appears to be a new one and on the increase. Dr. Whittle, of Nelson, makes the remark that if the disease is new it must be due to a vitamin or other dietary deficiency. In this part of the world shortage of vitamin C appears most likely. Recently one of us has seen a case which *may* have been acute regional ileitis. The patient was a very spare female, aged 60, with extraordinarily lax abdominal walls; onset, acute pyrexia and vomiting; sausage-shaped mass palpable, extending from right iliac fossa to pelvis in midline; complete recovery within a week on a diet of 12 oranges a day; only after the fourth day did traces of vitamin C appear in the urine, but she also had sulphamezathine in adequate doses.—We are, etc.,

O. WILSON.

Nelson, Lancs. T. D. CULBERT.

Air Embolism

Sir,—Reading through the interesting account of two cases of air embolism by Dr. P. H. Dalgleish (Aug. 25, p. 256), I think that the attention of any tuberculosis worker would be at once arrested by the statement: "A little air, less than 50 c.cm., *was blown through* to clear the needle." I do not think that such a procedure would have been considered proper at the majority of clinics or sanatoria. The most probable procedure on getting a dubious manometer reading would have been the removal of the needle and its reinsertion at another site.

In the final paragraph of Dr. Dalgleish's article he says: "These cases emphasize the points made by Hamilton and Rothstein (1935): that the *common practice* of 'blowing a little air through the needle to clear it' is one not unaccompanied by danger, and is in fact to be firmly discouraged." In face of this warning it seems strange that it should have been disregarded.—I am, etc.,

Southborough, Tunbridge Wells. E. Weatherhead.

Syphilitic Reinfection after Penicillin Therapy

Sir,—The following case record illustrates the curative effect of penicillin therapy in primary syphilis inasmuch as the patient, after being treated with penicillin for a primary chancre, returned to this unit in a short space of two months with a second primary sore.

A young African (aged 22) was admitted to the treatment centre where we are serving on March 5, 1945, with a primary chancre of the peno-scrotal junction on the right side. This was a typical indurated sore, and the dark-ground microscopy revealed the *Treponema pallidum* in the serum of the sore. The Kahn test was negative. A course of 2,400,000 units of penicillin was given (40,000 units intramuscularly every three hours for 7½ days). The patient was discharged on March 21 with the sore completely healed.

On May 29 the same patient was readmitted to this centre. He now had an indurated sore of the shaft of the penis, on the left side, with all the characteristics of a primary syphilitic chancre. The dark-ground microscopy revealed the presence of the *Treponema pallidum* in the sore. The Kahn test was − + 1, one plus (weak positive) on May 30. The scar of the old sore was both visible and palpable, and quite separate from the new sore.

Our thanks are due to Brig. R. P. Cormack, D.D.M.S., for permission to publish this observation.—We are, etc.,

"Under the Influence"

Sir,—The attention drawn by Dr. C. E. Meryon (Aug. 18, p. 234) to the increasing legal difficulty of obtaining a conviction for dangerous driving under the influence of alcohol indicates that the time may have come for the medical profession to suggest that the law be altered. In addition to the type of case he quotes, in which legal skill is able to exonerate a driver who was obviously intoxicated at the time of examination, there is another still more difficult to convict. Laboratory experience on the effects of small doses of alcohol rapidly absorbed demonstrates quite clearly that it is possible for a driver to be involved in an accident because he is under the influence of alcohol and yet be completely sober 15 to 20 minutes later when tested at the police station and, incidentally, show a blood alcohol concentration regarded as non-intoxicating; the disturbance of cerebral function occasioned by a relatively low concentration, if this is increasing rapidly, disappears when the peak has been passed.

On the other hand, a driver may be in an advanced stage of apparent inebriation when seen at the police station, and although this is the obvious cause of the accident in question, he will be acquitted if the effect is not due to alcohol. A glaring example of this legal anomaly was recently reported in the lay press: following the accident the driver was found in a semi-comatose condition, but because this was due to insulin he was acquitted by the magistrate.

If the purpose of the law is to protect the public against dangerous driving, the action of the driver is surely of greater importance than the possible causes of his action. Dangerous driving should itself be the serious offence. Legal discussion as to the meaning of dangerous driving could be no more involved than that occasioned by the existing law to which your correspondent has drawn attention, and medical men would be free to spend their available time in work of greater social importance.—I am, etc.,

London, W.C.1. M. Grace Eggleton.

? Abuse of Sulphathiazole

Sir,—I have read with interest Dr. P. Robinson's paper on "Penicillin for Haemolytic Streptococcal Throat Infections" (Aug. 18, p. 213), and observe that this has given satisfactory results where sulphathiazole has in many cases failed either to cure the condition or to prevent complications such as peritonsillar abscess, erythema nodosum, and acute rheumatism. On reading the case notes I have, however, been asking myself why this sulphonamide preparation has been chosen and not the ordinary sulphanilamide.

Since the discovery of the various preparations of the sulphonamide group I have carefully studied articles on their action and indications in the *B.M.J.*, and was given to understand that the original sulphanilamide proved most effective in streptococcal and *B. coli* infections, that sulphapyridine was most useful in pneumococcal infections, and sulphathiazole in infections with staphylococci, meningococci, and gonococci—to mention the chief indications. I have also learnt that the toxicity increases from sulphanilamide via sulphapyridine to sulphathiazole, resulting in severe sickness, kidney damage, agranulocytosis, etc.

One of my patients, a baby, has been treated in hospital with sulphathiazole for pneumonia which was not proved to be staphylococcal—it was most probably the usual pneumococcal type. No overdose was given, but the baby developed a nephritis which has become chronic. I asked myself if the same would have happened with sulphapyridine, which I usually give with excellent results.

I have heard of patients complaining of extreme nausea and sickness when receiving sulphapyridine for tonsillitis. I have treated for years now all cases of tonsillitis and tonsillar abscess—which are mostly streptococcal in origin—with the original sulphanilamide, and have always obtained good results without observing either toxic symptoms or complications, provided treatment was instituted in good time. Ordinary pneumonia I have treated with sulphapyridine and found this entirely effective. Only cases with proved staphylococcal or doubtful other infection I treated with sulphathiazole, and was again extremely satisfied with results. Since infectious fever and V.D. cases are usually treated in special centres I had not much opportunity for using sulphonamides on these.

I want to put these observations on record to show that with careful choice sulphonamides are usually adequate in treating most infectious conditions and only seldom—e.g., in osteomyelitis—is penicillin required. If I am mistaken I should be most grateful if an authority on the subject would correct me.—I am, etc.,

Spennymoor, Co. Durham. E. Brauer.

March Fracture

Sir,—I have just read the letter from Sir Lenthal Cheatle (July 28, p. 134) under the above title, and I feel that, having been regimental medical officer to a battalion of His Majesty's Brigade of Guards for a number of years, I am in a position to answer his question as to what the medical officers are doing about "this ugly, ridiculous ritual" of the stamping of feet on drill parade, which is so integral a part of the Brigade particularly. I pointed out to the adjutant and to the regimental sergeant-major of the battalion the opening passages of *Foot Drill, All Arms,* which state that noisy stamping of the feet is strictly forbidden. I was at that time seeing a considerable number of guardsmen who were suffering disability as a result, in my opinion, of this ritual. The adjutant's response was that he could see no reason why I should be any more successful than generations of medical officers before me who had tried to get this instruction enforced, and the sergeant-major denied that any stamping of the feet was being practised, saying that the men merely "put their feet smartly to the ground." The A.D.M.S. appeared to be powerless in the matter, so there it rested.

Thus the answer to Sir Lenthal would seem to be, "Nothing, because there is nothing to be done." For obvious reasons, I must regretfully remain,

"PEDES PLANI DOLENTESQUE."

Whooping-cough Vaccination

SIR,—With regard to the article on whooping-cough vaccination by Drs. A. M. McFarlan, Elizabeth Topley, and May Fisher (Aug. 18, p. 205) perhaps the results in a general practice scattered over a wide area, including a large town and a number of villages, may be of interest.

In the last six years I have done over 300 children, 95% of them at the age of 12 months, and 95% of them with a combined diphtheria and whooping-cough vaccine. So far there has not been a single case of whooping-cough (or diphtheria, for that matter) among the cases, although the majority of the children have been living in districts where epidemics have occurred. We have had a mild whooping-cough epidemic each year for the past six years.

The parents of a child living in a village four miles from here, whom I vaccinated three years ago at the age of 1 year, informed me only yesterday that her boy and another, whom I vaccinated about the same time, living in the same street, were almost the only two children who did not require to stay away from the village school during a recent whooping-cough epidemic. These numbers may be too small to form any real decision, and some of the children may have been naturally immune, but I feel that the results warrant me to continue the practice.—I am, etc.,

Leicester. A. MORRICK.

Climate and Health

SIR,—Dr. Macdonald Critchley's Croonian Lectures on "Problems of Naval Warfare under Climatic Extremes," published in your issues of Aug. 4, 11, and 18, contain conclusions that are open to question. In a paper, "Health and Climate," published in the *Malayan Medical Journal* for December, 1932, I pointed out that (1) man can live in any part of the world where he can obtain food and water, but (2) he enjoys health and energy, physical and mental, leading to the highest state of civilization only in certain regions with an optimum climate (Western Europe, South-East Canada, and Eastern and Central U.S.A.); and (3) though he can colonize a tropical country, his children there, at any rate, will suffer physical and mental deterioration. As an example of physical deterioration, even in the first settlers, there is presbyopia, which comes on many years earlier among tropical peoples and among whites who have lived long in the Tropics than it does among the inhabitants of an optimum climate.—I am, etc.,

London, S.W.1. KENNETH BLACK.

Methodology in the Curriculum

SIR,—I should like to express my agreement with the general argument in the article on premedical zoology by M. Abercrombie and M. L. Johnson (Aug. 25, p. 262) and my particular support for their plea for the deliberate teaching of scientific method to students. As long ago as 1932, in the discussion in your columns on medical education initiated by an article by Dr. C. M. Wilson (now Lord Moran), I suggested the same thing—the addition of the subject of methodology to the curriculum. I said then: "The student should be given the opportunity of becoming acquainted with and developing the rational attitude of mind. He should be encouraged in the attitude of intelligent scepticism as distinct from that of constant acquiescence in dogmatic teaching. He should be made aware of the necessity of distinguishing between assertion and proof, between a reason and a rationalization, and should be helped towards acquiring some knowledge of the personal bias." I would add now that this should include the set teaching of the correct principles of reasoning, otherwise logic, but not, under any circumstances, the traditional system.

The further point that follows again needs accentuation. The addition of another subject to the curriculum, combined with the constant increase in medical knowledge, must lead inevitably, as I pointed out in the same correspondence, to further specialization. The student will be compelled before qualification to drop certain subjects and "specialize" in the rest. I see no escape from this position, and suggest it would be wise to prepare for it and begin to work out its medical and social implications.—I am, etc.,

London, W.1. FREDERICK DILLON.

Premedical Zoology

SIR,—The paper on this subject in your issue of Aug. 25 is convincing and long overdue.

As I remember, my medical zoology course was largely confined to protozoa, earthworms, and the dogfish, while the science course was devoted entirely to snails. I did acquire some understanding of the common heritage of all vertebrates—the notochord, primitive streak, cranial nerves, etc.—but also a great deal of useless mental lumber which I proceeded to forget as soon as possible. Long after qualifying I acquired the *Beast Book for the Pocket* by Edmund Sanders, and I am sure I learned more from it than from my university course. This, I should say, is the sort of textbook for future doctors, and it can be read with interest and profit by a schoolboy. If, as I believe, a good doctor should be a naturalist and know something about most living things and their mutually dependent ways of living. I suggest dogfish have had their day and pigs, sheep, and horses might be considered instead, or even rabbits.

My own university was no worse than any other, I am sure. Therefore I would like to sign this letter merely,—Yours, etc.,

"M.D., B.Sc."

Doctors and the Social Trend

SIR,—As I sat through the last Annual Representative Meeting I wondered how the B.M.A. could possibly have chosen such a time for its deliberations. Surely it was political ineptitude to continue as if the caretaker was bound to be the new landlord. I wondered, too, how those of us who voted for the Labour Party could help to avoid the complete break-up of the Association if a Labour Government came to power with a clear mandate for new health services. For throughout both of the last two Representative Meetings there seemed to be a tacit agreement to ignore the results of the B.M.A.'s own questionary—results which showed that a majority of medical men would in all probability accept service under a National Health Service planned on the lines of the White Paper. When the Election results became unmistakable the suggestion arose that we must therefore close our ranks. Certainly, but do we close them for work with the people, or against them? Dr. J. Shackleton Bailey (Aug. 18, p. 235) has shown us the way out in one of the most constructive and understanding letters that has appeared in our *Journal*.

The Government has now a clear mandate to put into action the Labour Party's policy on a National Health Service. Our Association has objected in the past that changes in the health services should be preceded by such improvements in living and working conditions, in housing, and in nutrition that must eventually reduce the incidence of disease in the best way. The new Government is entirely in agreement that this approach is correct, and consequently housing and social security are among its first intentions. But this, as regards health, is long-term policy and sickness rates will not decrease immediately, so that reform of our curative health services cannot be postponed.

In its negotiations with the Ministry of Health the B.M.A. has shown itself capable of constructive policy. For example, it induced the Minister to accept the proposal that reform of the mental health services should be part of the new National Health Service. We can, however, go much further, and with a willing Government show the Ministry of Health how to design a new health service so that industrial, maternity, and mental services can all be integrated with the hospitals and health centres; not, indeed, that all these should be at once incorporated, but that the scheme should be so designed that all these services can be operated by the same administrative machinery as and when sufficient trained personnel become available.

We have nothing to lose by co-operating constructively with the Government. The Association's miserable attempts to save private practice by a scheme to finance the purchase of practices has been exposed by Dr. Robert Poots (*Supplement*, Aug. 11, p. 43), and it can lead to nothing but a lower standard of life for general practitioners. I need not repeat his arguments, but any demobilized doctor would be wise to study Dr. Poots's analysis of the figures before becoming the servant of the banks rather than assuming the more dignified position of a servant of the people.

My years in the E.M.S. have taught me the pleasure of whole-time medical service. I have been equally frustrated by the administration in local authority hospitals and in voluntary hospitals. But in the former the particular local authority concerned, after many misunderstandings and a tough struggle, now prides itself on its medical and staff committees and on its increasing decentralization of control. A Labour Government must encourage democratic methods, and we must, therefore, seize the opportunity to show it how best to organize the services so that all health workers, nurses, medical auxiliaries, and others as well as doctors can best influence and guide the development of the new service. We must, too, give up talking about health centres as if they are something too difficult to design without prolonged experiments, thereby betraying ourselves as incapable fools without the wit to plan the next step forward.

The B.M.A. must now choose between two alternatives. On the one hand, obstructive tactics and the opposition of private to public interests can only lead to loss of respect by the public for the profession, and to the collapse of our professional organization. On the other hand, tempered criticism, constructive assistance, and an understanding of inevitable social trends will lead not only to a rehabilitation of the profession but to a development of health services which will put the whole of modern medical science at the disposal of the people. Dr. Shackleton Bailey has given us a clear lead.—I am, etc.,

Wimbledon, S.W.20. HUGH GAINSBOROUGH.

SIR,—It is a pleasure to read Dr. J. Shackleton Bailey's letter and a pity that such clear thinking is not more common. As he says, the world is undergoing a great upheaval and what is wanted is a change of attitude of mind. The *raison d'être* of the medical profession is the maintenance of the health of the community. Ill-health was not sent by a beneficent being for exploitation by a professional class, and, provided the State grants its practitioners a reasonable remuneration, the removal of the monetary value of individual patients might prove of moral value in itself.

The profession would have been better advised if, in its dealings with the Government, it had adopted a spirit of willing co-operation in evolving the best possible system rather than one of resistance to an inevitable and probably beneficial change.—I am, etc.,

Wanstead Park. M. STARK.

Day Nurseries

SIR,—Dr. F. Gray (Aug. 25, p. 267) finds my statements fantastic, and therefore I ask to be allowed to say that the pre-war day nursery which I described, and of which I had an intimate knowledge, accepted between 40 and 50 children daily. In each case the father came under one of the headings quoted in my previous letter. In each case "the home" consisted of one or two "let-off" rooms. I gladly agree with Dr. Gray that such cases are a minority, but they do exist and must be helped.

But what about the majority—i.e., the man and wife: he in his job, and she occupied with her house duties? I suggest that if the scope of the day nursery were extended also to provide part-time service for them according to their individual needs and circumstances they would thereby be stimulated, encouraged, and assisted to add to the population. In addition, the valuable contribution that a well-managed day nursery can make towards hygiene, education, and social behaviour of the child in its most formative years must not be overlooked.

Dr. Gray and I are on common ground in deploring the fact that the young mother with a child should go out to work, and be underpaid into the bargain, but I think he is mistaken in laying the blame at the door of the nursery. Such a line of thought could lead us to accuse the hospitals and health clinics of promoting disease.—I am, etc.,

London, N.W.11. L. S. WOOLF.

Catalogue of Medical Films

SIR,—A catalogue of all the medical films in Great Britain is now being prepared by the Royal Society of Medicine in co-operation with the Scientific Film Association. It would be appreciated if any persons holding films of medical or paramedical interest, who have not already been asked for details, would communicate with the Film Cataloguer, Royal Society of Medicine, 1, Wimpole Street, W.1. By so doing they would not commit themselves or their films, but would enable the catalogue to be complete.—We are, etc.,

GORDON GORDON-TAYLOR,
President,
Royal Society of Medicine.

ARTHUR ELTON,
President,
Scientific Film Association.

The Services

It has been announced by the War Office that the release of medical officers will be proceeded with up to Group 23 by Jan. 20, 1946, in step with the rest of the Army.

The Central Medical War Committee is informed that the rate of release of medical officers from the Royal Air Force has been accelerated. The following age and service groups will be released by the dates shown: By Oct. 31, Groups 13 and 14 (i.e., additional to Groups 11 and 12); by Nov. 30, Groups 15 and 16; by Dec. 31, Groups 17 and 18; by Jan. 31, 1946, Group 19; by Feb. 28, 1946, Group 20.

Lieut.-Gen. Sir Alexander Hood, K.C.B., C.B.E., M.D., F.R.C.P., late R.A.M.C., Director-General of Army Medical Services, on completion of tenure of appointment is retained on the Active List (supernumerary).

Major-Gen. S. R. Burston, C.B., C.B.E., D.S.O., E.D., A.A.M.C., has been appointed Honorary Physician to the King, *vice* Brig. D. M. McWhae, C.M.G., C.B.E., V.D., A.A.M.C., who has resigned the appointment.

Temp. Surg. Lieut. Arthur Morton Evans, R.N.V.R., has been awarded the D.S.C. for bravery, determination, and devotion to duty in an action with shore batteries off Andaman Island on March 19, 1945, and in successful attacks on enemy submarine chasers and merchantmen on March 26, 1945.

Capt. Robert Barer, R.A.M.C., has been awarded the M.C. in recognition of gallant and distinguished services in North-West Europe.

Lieut.-Col. (Acting) A. D. MacPherson, R.C.A.M.C., has been awarded the D.S.O. in recognition of gallant and distinguished services in North-West Europe.

Major J. A. Wright, R.C.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services in North-West Europe.

2nd Lieut. Harbans Singh, I.A.M.C., has been awarded the M.C. in recognition of gallant and distinguished services in Italy.

The King has conferred the Efficiency Decoration upon the following medical officers of the Territorial Army: Lieut.-Col. G. T. Hankey; Majors (Temp. Lieut.-Cols.) H. W. Bambridge, R. E. M. Fawcett, E. Hutcheon, F. L. Ker, P. J. May, M.B.E., and D. N. Nicholson; and Majors R. V. Facey, H. V. Ingram, and D. P. MacIver, M.C., R.A.M.C.(T.A.).

CASUALTIES IN THE MEDICAL SERVICES

Flight Lieut. SAMUEL LLOYD JONES died on July 29 while on sick leave after being invalided from over-seas. He was born on Feb. 9, 1913, and studied at the Welsh National School of Medicine, qualifying M.R.C.S., L.R.C.P. in 1940. After holding appointments at Swansea General Hospital and as assistant medical officer of health, Merthyr Tydfil, he received a commission as flying officer in the R.A.F.V.R. on Oct. 17, 1941.

Killed.—War Subs. Capts. Alexander Brown and David Frew Wood, R.A.M.C.

Died abroad, as the result of an accident.—Surg. Lieut. Angus Charles Macrae-Gibson, R.N.V.R.

Died in India.—Major Alfred Charles Greene, I.M.S.; Capt. Jean Cunison Nelson, R.A.M.C.

Died in Bermuda.—War Subs. Capt. John Michael Hamer, R.A.M.C.

Died.—Lieut. Gerard Baum, R.A.M.C.

Wounded.—War Subs. Capt. S. Hyman, R.A.M.C.

Obituary

ERIC BIDDLE, *M.C.*, M.B., B.S.

We regret to announce that Dr. Eric Biddle, pathologist and transfusion officer at the East Suffolk and Ipswich Hospital, died on Aug. 21 as the result of a motor accident. He had been chairman of the East Suffolk Division of the B.M.A. in 1939–40 and was elected president of the Suffolk Branch last year. A student of Guy's Hospital, he qualified M.R.C.S., L.R.C.P. in 1915 and after service in the last war as major, R.A.M.C., during which he won the Military Cross and bar, he took the M.B., B.S.Lond. in 1922. At Guy's Eric Biddle held appointments as house-surgeon, out-patient surgical assistant, and senior assistant bacteriologist. He was later assistant in the venereal disease department of the Royal London Ophthalmic Hospital and pathologist to the Devonshire Hospital, Buxton. He joined the B.M.A. in 1926 and was a member of the Pathological Society and the Association of Clinical Pathologists. He published a report on the bacteriological investigation of arthritis in the *Journal of Clinical Research*, and contributed to the *British Medical Journal* in 1939, jointly with Mr. G. F. Langley, a paper on transfusion with conserved blood. His last published writing was a letter in these columns on May 26 of this year in which he put pertinent questions on the subject of blood donors and transfusion services under post-war conditions. In common with many other transfusion officers he was faced with a transition period in which drastic and serious fall in the number of donors must be expected and a resignation of many of the voluntary staff who had helped him during the war.

A. R. H. writes:

The tragic and sudden death of Eric Biddle has come as a shock to his many medical and lay friends in Ipswich and East Suffolk. He came to us from Guy's, where he was senior assistant bacteriologist. As pathologist to the East Suffolk and Ipswich Hospital, he had been in charge of the laboratory since his appointment in 1927 as its first director. In 1928 the new pathological laboratory was officially opened in Ipswich by the Princess Royal, and from then until now, under his able direction, it has grown both in the scope of its work and in its usefulness to the hospital and the area which it serves. During the war years the work of the department became more and more exacting. Dr. Biddle organized a most efficient blood transfusion service which he built up from small beginnings before the war. Latterly he had as many as 172 donors at one session, and averaged 100 donors at each fortnightly session. All this he did and much more outside the terms of his appointment, and always cheerfully and ungrudgingly. He undertook research in penicillin, and his interest in the forensic side of medicine resulted in his services being sought by the authorities to find the cause of death in obscure or suspicious circumstances. He was medical officer to the 9th Suffolk Home Guard and carried out his duties with characteristic enthusiasm. A keen photographer, he was an active member of the Ipswich Photographic Society, and would always help a colleague with photographic evidence for publication or for filing with clinical data. The Music Club for Nurses, which has afforded much entertainment and recreation to the nursing and resident staff, was founded by him. His keen sense of humour and ready wit—free from cynicism or invective—were a joy to us all. Those of us who knew him as a friend and colleague feel the loss of a genial and kindly personality who was always eager to render service at any time and in any emergency.

A. P. BACHA, M.B., B.S., F.R.C.S.

India has lost a pioneer surgeon by the death of Dr. Ardeshir Pestonji Bacha on May 5. He was born in 1881 at Navsari, a town near Bombay in the Baroda State Territory. He passed the matriculation examination from the local high-school and joined the Grant Medical College in Bombay in 1898, where he passed all his examinations in the first class and won scholarships, prizes, and medals. He graduated from the Bombay University in 1903. After working for a short time as a house-surgeon in Dr. Masina's private hospital he secured the Tata Scholarship for further studies and joined University College, London, where he passed the M.B., B.S.Lond. in 1907 and F.R.C.S.Eng. in 1909. He returned to India early in 1910. At that time the Grant Medical College and the Jamsetjee Jeejeebhoy group of hospitals were the only teaching institutions in medicine in Bombay, and they were entirely staffed by I.M.S. officers. At about the beginning of the century Dr. H. M. Masina, F.R.C.S., had started a private hospital, the first of its kind in Bombay. In 1910 Dr. Bacha started a modern nursing home, and by dint of sheer merit he gradually built up a good surgical practice. Since then Bombay has got the new G.S. Medical College, with the K.E.M. Hospital attached to it, the Jerbai Wadia Hospital for Children, the Tata Memorial Hospital for Cancer, and many other hospitals, all staffed by capable Indian medical men and women.

J. B. D. writes:

Dr. Bacha was a keen student of contemporary medical and surgical literature. He subscribed to the leading British and American medical journals and read them carefully. He also bought all the best books published during the last thirty-five years, and the collection in his splendid library had cost him a very large sum. He was also equally lavish in the acquisition of the best appliances and instruments for his work, the latter being also of great value. He took great pains over the minutest details of operations and the after-care of his patients, and thus built up a thoroughly well deserved reputation as a most careful and successful surgeon. Throughout his life he remained a close student of the latest developments in the field of general surgery. He was a staunch Indian Nationalist, though during the later period of his life he greatly deplored the disruptive and communal tendencies in the Nationalist movement which have developed later. During this war he gave his services to the war-wounded as a lieut.-colonel, I.A.M.C., till he was incapacitated by his last illness, and for these he was thanked by Col. Sir Jamshedji N. Duggan, I.A.M.C., the head of the war hospital in Bombay. He was a member of the British Medical Association for over forty years, and a past-president of the Bombay Medical Union. He was surgeon to the Parsi General Hospital and surgeon and lecturer in surgery to the King Edward Memorial Hospital. He was an examiner in surgery for the M.B., B.S., and the M.S. degrees of the Bombay University. He cherished the highest ideals of our profession, and was very strict and uncompromising in his observance of those ideals. I had the privilege of an unbroken intimate friendship with him for fifty years. He was a pioneer Indian surgeon who has set a very high standard for others to follow—one who would have been acclaimed as an outstanding surgeon in any country.

ALFRED SALTER, M.D.

Dr. Alfred Salter, who died in Guy's Hospital on Aug. 24, at the age of 72, first entered the House of Commons as Labour member for West Bermondsey in 1922. He lost his seat in the following year, but regained it in 1924, and held it until his retirement at the recent dissolution. His political activities overshadowed his achievements in medicine, which in his earlier years gave promise of a brilliant career. He was a Guy's man, qualifying in 1895, when he took the gold medal in medicine and triple first-class honours in the London M.B., and in the following year he proceeded M.D., again with gold medal. In 1897 he won the Golding Bird gold medal and scholarship in public health and the Gull research scholarship in pathology. After holding an appointment as house-physician and resident obstetrician at Guy's he became bacteriologist to the Lister Institute of Preventive Medicine, where he remained for three years, and contributed many papers on bacteriological and pathological subjects to French and German as well as English periodicals. His ardent sympathy for and championship of the poor led him into general practice in a working-class district, and he became the senior member of a large partnership in Bermondsey, where he was a well-known figure going on his rounds on a tall bicycle and wearing even in those days the flaming Socialist tie. The woeful condition of the people in some parts of London even as late as the early years of this century caused him to take up various forms of social and religious philanthropy—he would give an address in a little mission hall on a Sunday evening, and then rush off to perform a minor operation, afterwards going on to his adult school or his lads' club—and to become a member of his borough council (of which he was an alderman at the time of his death), of the County Council, and of Parliament.

A correspondent who had known Dr. Salter for over forty years writes:

He was one of those rare spirits who combine the pacifist approach in public affairs with an extreme militancy in propaganda. He was a "bonny fighter," and never feared to cause dismay in the ranks of his friends by his extreme views and forthright utterance. Had he been more accommodating in his conscience he might have won a higher place in politics; as it was, he remained a back bencher while men in his own party far less richly endowed than he, whether in intellect or in moral strength, pushed their way to leading places. Unlike a good many of his friends, he was a pacifist not only in the first but in the second European war. His pacifism was based on a strong religious conviction concerning non-resistance. He was equally resolute in his condemnation of the drink evil. Not long after he entered the House of Commons he created a stir by declaring in a public speech that he had seen many members drunk in the House, and that no party was exempt from this disgrace. The House could do no other than take cognizance of such a statement, and it placed on its records a resolution that Dr. Salter's words were a gross libel and a grave breach of privilege. But there is little doubt that at that time, with many new men entering Parliament, unaccustomed to its long hours and tedium, and finding there a bar which was not subject to licensing restrictions, Dr. Salter had good ground for his statement; he refused to apologize for it or amend or withdraw it. Similarly he was a great champion of free speech, and he actually resigned from the Labour Party in his own borough, which he had founded thirty years previously, because it refused free speech to Fascists. No one more than he detested Fascist tyranny, but it was exactly because he detested it that he was anxious that it should not be imitated by his friends.

In medical politics he took little part (he ceased membership of the British Medical Association in 1913), but he was an active member of the London Panel Committee in its early days, and scarcely a meeting passed without some rising of temperature due to his spirited interventions. Like many men with his sharp tongue and pugnacious jowl, he was, to those who knew him intimately, of the gentlest disposition. His deeds of kindness as a doctor, especially to the very poor, were a legend in South-East London, and in his elections his personality won the support of many who could not abide his politics. He was extraordinarily fortunate in his domestic life. Ada Salter, who died three years ago, like himself a member of the Society of Friends, fully shared her husband's ideals and helped him in his struggles. She was for many years a member of the L.C.C. and was actually mayor of Bermondsey when that borough first returned her husband to Parliament. He felt her loss keenly, and had been in failing health for some time.

It is with regret that we announce the death of Dr. Samuel John Watt Donald, of Brook Street, Sutton-in-Ashfield. Dr. Donald was 54 years of age, and had been ill since last December, but during recent months he appeared to be making progress. The news of his passing was received with deepest regret throughout the district, where his sterling qualities and kindly disposition endeared him to every section of the community. A native of Ballyrickard, Ireland, he graduated M.B., Ch.B., and B.A.O. at Queen's University, Belfast, in 1916; he immediately joined the Forces, and was sent to the Middle East, serving under the late General Allenby in Palestine, Iraq, and India. Later he completed his services with the Army of Occupation in Germany as a divisional D.A.D.M.S., and subsequently settled at Sutton-in-Ashfield until his untimely end. Among his other activities he took an enthusiastic interest in the St. John Ambulance Brigade; having begun in 1920 as a division surgeon he rose to the highest position in the county, that of County Commissioner. He attained the meritorious award of Serving Brother and Officer of the Order of St. John. During the war, amidst a very busy life, he joined the Home Guard as a major, and acted as C.M.P. for the Army. For some time it was evident that he was working under great mental strain. During his long illness that followed, many were the anxious inquiries of his friends, and they hoped against hope that he would be spared to enjoy some little respite from his arduous toil. He was truly one of the war's casualties.—P. M. G.

The many friends of the late Dr. John L. Moir in Anglesey and Cheshire learned with regret of his unexpected death at the age of 63. John Lowndes Moir, second son of the late John Moir, J.P., Brereton Hall, Sandbach, was born in 1882. Educated at Charterhouse School, Manchester University and Medical School, he graduated M.B., Ch.B. in 1908. Following the house-appointments of junior and senior H.P. and senior H.S. at the Manchester Royal Infirmary, he practised at Congleton, Cheshire, from 1910 to 1931, holding the appointments of honorary medical officer Congleton War Memorial Hospital, certifying factory surgeon Congleton district, M.O. to the Post Office, and recruiting M.O. Congleton and district. From his retirement in 1931 John Moir lived at Cemaes Bay, Anglesey. He was called to the Bar by the Middle Temple in 1935 and became a member of the Northern Circuit. He volunteered for the R.A.M.C. in the last war but was rejected on medical grounds, and again volunteered at the outbreak of the present war, but his services were refused as he was over age. Moir then devoted his time to the work of the British Red Cross Society and Order of St. John, and became county medical officer and county civil defence officer of the Anglesey B.R.C.S. On the inception of the Home Guard he was made zone medical adviser with the rank of lieut.-colonel, and for several years undertook the whole of the medical work for the Anglesey County Home Guard unaided. G. P. W. writes: A staunch colleague and a great upholder of the dignity and traditions of his profession, John Moir gave of his utmost to any cause he took up. Prospective Conservative candidate for Ardwick, Manchester, from 1939 to 1944, he was the author of many pamphlets on medico-legal, medical, and religious subjects; a fluent speaker, he often addressed public audiences on these matters. In June, 1945, he was appointed by the Lord Chancellor to the post of medical member of the Pensions Appeal Tribunal, and was engaged on this work up to the time of his death. Deeply religious, he gave freely of his time and energy to any individual or organization he deemed worthy of help, and gave of his best to his patients, rich or poor, irrespective of the financial reward. In his practice at Congleton he was truly the "beloved physician," and innumerable old patients mourn his loss. His epitaph, chosen by himself some years ago, typifies his life: "We are more than conquerors through Him that loved us" (Romans viii, 37).

Dr. Arthur Murray Wood, late of Leith, who died at Cockburnspath on Aug. 19, graduated M.B., Ch.B., with first-class honours, at Edinburgh University in 1900 and proceeded M.D. four lears later. He was elected F.R.C.P.Ed. in 1915 and took the D.P.H. of Edinburgh and of Glasgow. He had been resident physician at the Edinburgh Royal Infirmary and at the Sick Children's Hospital, and not long after graduation held office as senior president of the Royal Medical Society of Edinburgh. Dr. Wood served for more than 15 years as physician in charge of wards at Leith Hospital, and was afterwards appointed to the consulting staff of that institution. He devoted much time to the teaching of ambulance work in Leith, and for many years examined in first-aid work at Leith Nautical College. He joined the B.M.A. in 1911 and remained a member until the end of last year, when ill-health had overtaken him. His two sons are doctors, and one of them carries on the family practice.

Dr. Joseph White, after many years spent in active practice in London, retired to Bournemouth in the early days of the present year. His anticipation of a well-earned rest was but briefly realized, and he died on Aug. 19. Of him, in a short sentence, it may be justly written that he was born a student and that he lived a student. His record at the University of Glasgow was set in due sequence in the Faculties of Arts, of Science, and of Medicine, and the degrees of M.A., B.Sc., and M.B., C.M. were each awarded to him with the distinction of "Honours"; he gained also a much-coveted prize in the shape of the Clark Scholarship. After graduation he continued his studies at Paris, Berlin, and Vienna, with particular attention to midwifery and gynaecology. Thus the fates seem to indicate for him a promising academic career. Yet his choice in the end was for the wide fields and opportunities of general practice, and he applied to these both a trained professional equipment and a personal enthusiasm and devotion. Little wonder that he quickly gained the confidence and regard of patients of all classes, for his ideal was one of service and his purpose was to realize this. With a trained mind and a high standard of accuracy he combined a gentleness of thought and understanding which engaged the affection of his patients and the regard of his colleagues. He knew well the charm of friendship and the values of the domestic atmosphere. In a word, in Dr. Joseph White were seen the modest scholar, the effective practitioner, and the honest man, and his record of service is quietly but firmly written. To his wife and family many friends and colleagues will desire to offer a tribute of sympathy and regard.—C. O. H.

Dr. G. N. P. Carrell died suddenly at his home in Kingswood, Surrey, on Aug. 28. He was in his 90th year. Carrell was a student at Guy's in the 'eighties, and a contemporary and friend of Hale-White and Charters Symonds. He qualified M.R.C.S., L.R.C.P. in 1889 and was clinical assistant in the ophthalmic department. He went into practice at Ilford in 1894 and worked there for nearly 40 years. In that time he saw the small village grow into a large town. Its citizens owe a great deal to his long and devoted service. Carrell was a good doctor and a good man. The many thousands who were his patients will remember his charm, his humour, and his great affection. I know of no one who more closely approached the ideal of the family doctor. He married Sage Ward Haddow in 1894, who survives him. His son, Guy Carrell, is a surgeon lieut.-cmdr. in the R.N.V.R., and his daughter, Enid, is the wife of Lieut.-Col. Cokkinis, R.A.M.C., of St. Mary's.—A. J. C.

Universities and Colleges

UNIVERSITY OF OXFORD

The following medical degrees were conferred at the end of July:

D.M.—J. C. Neely.

B.M.—D. W. H. Barnes, David Gall, J. B. E. Baker, D. S. Cooke, D. St. C. Roberts, Elizabeth J. Horder, *D. G. Melrose, *Christopher Ounsted, *C. J. Radway, *J. S. Dismorr, Anthony Betty Shaw, N. T. Jace, G. E. Dixon, J. C. Lawrie, D. R. Wood, *C. H. Neville-Smith, *C. C. Draper, *J. D. L. Reinhold, *Mary Balf.

* Conferred in absence.

UNIVERSITY OF CAMBRIDGE

The following medical degrees were conferred at a Congregation held on Aug. 3. Only those whose names are marked with an asterisk received their degrees in person; all the other degrees were received by proxy.

M.D.—W. R. Billington, K. W. Donald, C. M. Fletcher, M. I. A. Hunter R. A. Shooter.

M.B., B.Chir.—N. K. Connolly, W. P. D. Ross, J. P. D. Mounsey, C. J. H. Paget, F. S. Sinker, R. H. Whitworth, C. G. Attenborough, R. E. B. Spencer, A. R. C. Butson, P. M. Jeavons, B. W. Pay, I. P. Williams, I. D. P. Wootton, A. R. Buckley, I. S. Hodgson-Jones, D. A. Pyke, M. G. Thorne, R. G. M. Longridge, William Waugh, A. M. H. Bennett, R. E. Church, J. M. Drew, J. W. B. Forshaw, J. B. Lawson, C. M. Monro, V. R. Pickles, David Wilkes, J. H. F. Wood, C. H. Kinder, A. J. Underwood-Whitney, J. M. Walshe, J. C. Sloper, James Crichton, A. G. Dingley, R. B. Wilson, J. A. Dew, P. F. Boreham, H. R. Mallows, J. R. Smythies, David Wilson, M. F. Bethell, R. A. Green, N. B. Malleson, J. R. Moffatt, K. M. Nuttall, O. L. Wade, S. P. Wrightson, J. F. Fisher, A. D. Beard, Emeric Halász; *N. T. Welford, *I. M. P. Dawson, *D. G. Abrahams, *G. R. E. Naylor, *K. E. E. Read, *D. A. W. Edwards, *D. W. S. Sheldon.

UNIVERSITY OF LONDON

Alterations in and additions to the regulations for diplomas and certificates administered by the University Extension and Tutorial Classes Council, including the postgraduate diploma in psychological medicine, have been published from the wartime address. All communications regarding these regulations should be sent to the University Extension Registrar, University of London, Imperial Institute Road, South Kensington, S.W.7. In 1946 all examinations normally due to begin between the dates June 10 and July 31 (both inclusive) will begin one week later.

The following candidates have been approved at the examination indicated:

Academic Postgraduate Diploma in Medical Radiology.—J. J. Stevenson *Part I:* R. Astley, J. Borrowdale, D. Brash, L. Ceballos, E. Giordani, G Hollingsworth, S. Josephs, Gwenllian B. Morgan, R. S. Murray, J. F. Nicholl A. W. O'Farrell, L. G. Picciotto, R. C. Tudway, F. Zammit.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The autumn course of professorial lectures on anatomy, applied physiology, and pathology will be delivered at the College, Lincoln's Inn Fields, on Sept. 24, 26, 27; Oct. 1, 3, 5, 8, 10, 12, 15, 17, and 18. Prof. John Beattie's course on applied physiology at 2.30 p.m. each day will be devoted to kidney function. Prof. R. A. Willis's course on pathology at 3.45 p.m. each day will be devoted to tumours. Prof. A. J. E. Cave's course on anatomy at 5 p.m. each day will begin with a series of demonstrations. All three courses are open to medical practitioners and advanced students.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

The report for 1944 of the curator of the laboratory of the Royal College of Physicians of Edinburgh (Dr. A. Fergus Hewat) states that the reports which have issued from the laboratory during the year numbered over 25,000, making a record. Dr. Cranston Low has been appointed superintendent of the laboratory. In mentioning that the research work has gone steadily forward, Dr. Hewat utters a warning against attaching too much mystery to the term "research" or suggesting that it must be conducted under conditions of cloistered seclusion. "It may be necessary to look for future activity of the laboratory on the lines of community service and to combine this work with appropriate research on the abundant material provided. . . . Research is not necessarily to be looked on as a set piece, or even as a major piece of work, so long as it does usefully contribute, like the individual brick, to a final edifice." Brief accounts are given of the work done under Lieut.-Col. W. F. Harvey in histology and haematology, and under Dr. W. O. Kermack in biochemistry. There are also departments of bacteriology and of mathematics and statistics. The histological collection of the laboratory together with clinically recorded tumour material, mainly of Edinburgh, is being used by Dr. Blackwood, pathologist to the Scottish mental hospitals, in an endeavour to make a comprehensive and critical survey of tumours of the nervous system—a study which will require a long period of analytical and statistical investigation.

Medical Notes in Parliament

Age Incidence in Diphtheria

Mr. Viant inquired on Aug. 21 what were the ages in the 23,152 cases finally diagnosed as of diphtheria in 1944 and in the 934 fatal cases.

Mr. Bevan said the particulars requested were:

Age Group	Cases	Deaths
Under 5	4,171	351
5–9	7,200	342
10–14	4,417	104
15–24	4,306	64
25 and over Age unknown	3,058	72 1

Mr. Bevan added that information about immunization was not available for all cases of diphtheria because it was derived from returns by local authorities relating to the immunization campaign, affecting only children up to the age of 15. These returns, moreover, do not include immunizations by doctors in private practice.

Milk

Dr. Summerskill said on Aug. 23 that progress toward enforcement of the standards of milk at the time of sale to the consumer set out in the White Paper had been disappointing. No areas had yet been specified under Regulation 55G. Until the deficiencies of plant, equipment, and buildings could be made good, imposition of heat treatment of milk upon all dairymen would not be practicable. Considerable progress had been made in this direction and the output of new plant was improving.

Mr. Bevan states that a high proportion of school milk is now either heat-treated or tuberculin-tested. He is consulting the Minister of Food on what further action can be taken respecting the supply of adequately heat-treated milk.

Tuberculosis in Ex-Service Men: Treatment Costs

Capt. Bullock on Aug. 22 asked the Minister of Health to reconsider the present arrangements relating to men discharged from the Army suffering from tuberculosis so as to ensure that their institutional treatment should always be a charge upon the State. Mr. Bevan said responsibility for treatment of tuberculosis rested upon local authorities. Where the Ministry of Pensions accepted tuberculosis in a man discharged from the Army as attributable to or aggravated by war service, payment was made by that Department to the local authority concerned at an agreed capitation rate in respect of approved cases of institutional treatment. In any other case the cost of such treatment was borne by the local authority's tuberculosis service, which attracted Exchequer grant.

Medical News

The conference of the Association of Special Libraries and Information Bureaux will be held during the week-end Sept. 15–16 at the Portland Hall (Polytechnic Extension Building), Little Titchfield Street, London, W.C. An inclusive fee of 30s. per head to members (£2 to non-members) will cover admission to all sessions, lunch and tea both days, and a free copy of the report of the proceedings. Application forms can be obtained from the Aslib office, 52, Bloomsbury Street, W.C.1.

A meeting of the members of the British Association of Physical Medicine will be held at 11, Chandos Street, W., on Wednesday, Oct. 24, at 5 p.m., when Dr. James MacDonell will read a paper on "Sleep Posture—Its Implications," to be followed by a discussion.

The address of the Socialist Medical Association is now 35, Long Acre, London, W.C.2.

According to a dispatch from the Delhi Correspondent of the *Times* the Government of India created on Sept. 1 a Department of Agriculture, a Department of Health, and a Department of Education, in place of the existing single Department of Education, Health, and Lands. Sir Sardar Jogendra Singh, Minister in charge of the conjoint department in the Viceroy's Executive Council, will for the time being take charge of all three departments of the central Government.

Dr. Cecil Gordon Roberts, second medical officer to the General Post Office, has been appointed Chief Medical Officer in succession to the late Dr. W. Logan Scott. Dr. M. C. W. Long, assistant medical officer, has been appointed second medical officer.

Courses of ten lectures on "The Psychology of Frustration and Fulfilment in Adult Life," arranged by the Provisional National Council for Mental Health, will be given at Sheffield, Leeds, Bradford, Manchester, and Liverpool throughout the ten weeks from October 1 to December 7. They will run concurrently, the weekly speakers and their subjects being: Dr. Edward Glover, "The Psycho-analytic Approach"; Dr. Lois Munro, "The Psycho-analytic Approach"; Dr. R. G. Gordon, "The Celibate Man"; Dr. Noel Harris, "The Married Man"; Miss Lloyd Baker, "The Celibate Woman"; Dr. Winifred Rushforth, "The Married Woman"; Principal J. H. Nicholson, "Co-education of Young Adults"; Dr. J. A. Hadfield, "Parenthood"; Dr. H. Crichton-Miller, "Frustration and Authority" and "Evolution and Fulfilment." Tickets (for the course, £1) and further information may be obtained from the offices of the Provisional National Council for Mental Health, 39, Queen Anne Street, W.1.

Officials of the Memorial Cancer Hospital, New York, have accepted a grant of $4,000,000 (£1,000,000) from Mr. Alfred P. Sloan, chairman of General Motors Corporation, to the Sloan-Kettering Institute for Cancer Research at the Memorial Centre. The grant will come from the Alfred Sloan Foundation, and half the money will be for buildings and the rest will provide $200,000 annually for ten years towards working costs. Dr. Charles F. Kettering, director of research at General Motors, will be responsible for the organization of industrial techniques for cancer research, but the Corporation will not concern itself with the programme of work. A public campaign is to be launched to raise the $3,000,000 to $4,000,000 required to complete the hospital.

The Minister of Health, the Right Hon. Aneurin Bevan, M.P., has appointed Major Donald Bruce, M.P., to be his Parliamentary Private Secretary.

Viscount Dawson of Penn, by his will, directed that unless conditions arising out of the war made it too difficult, or doctors in attendance thought no service to knowledge could follow, a post-mortem examination of his body should be made. "I do this because I think the public do not sufficiently realize the importance of post-mortem examinations being made and the advantages to knowledge and therefore to future generations which will thus accrue. We do not hesitate to have operations performed on our bodies when we are alive and when circumstances require it. Why, then, should we mind operations (which are done with the same care, the same gentleness, and I may add the save reverence) being done to our bodies when we are dead? Surely this is a rightful service which the dead should give the living. The benefit of such service to the living is very great."

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* the incidence of infectious diseases, with the exception of measles and dysentery, remained at almost the level of the preceding week. Measles returns were 354 fewer, and those of dysentery 41 fewer.

The trend of whooping-cough varied: notifications fell in the north and south, but rose in the midlands, the total for the country increasing by 31. Lancashire reported a rise of 14 in returns for diphtheria. The decrease in measles notifications was general, except for rises of 27 in Kent and 16 in Durham.

The only fresh outbreak of dysentery was in Cambridgeshire, 15 cases. The other chief centres of infection were Essex 52 (Maldon M.B. 39), Lincolnshire 33, Surrey 22, London 22, Middlesex 16, Glamorganshire 16, Lancashire 13, and Warwickshire 10.

Six cases, one fatal, of infantile paralysis have occurred among Ilford boys who recently returned from a Scouts' camp, and the sister of another boy has contracted the disease. The local medical officer of health has given the camp a completely clean bill of health, and considers the camp in no way responsible.

In *Scotland* diphtheria notifications rose by 18, and those for dysentery by 25. In Glasgow the incidence of dysentery rose from 13 to 28, and it was here also that more than half the cases of diphtheria were notified.

In *Eire* there was an increase of 16 in the notifications of diphtheria. The outbreak of diarrhoea and enteritis in Dublin C.B. rose from 54 to the very high level of 88 cases.

In *Northern Ireland* scarlet fever notifications rose by 21, and those for diphtheria by 9. Four members of one family in Londonderry have contracted typhoid.

Week Ending August 9

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,001, whooping-cough 1,152, diphtheria 409, measles 1,151, acute pneumonia 318, cerebrospinal fever 47, dysentery 232, paratyphoid 17, typhoid 12, poliomyelitis 31.

No. 33

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 18.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week)

---

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Owing to movements of population, birth and death rates for Northern Ireland are still not available.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London.*

ANY QUESTIONS?

Histidine and Peptic Ulcer

Q.—*In view of the experimental evidence that histidine is necessary for the adequate nutrition of the carnivorous stomach, and in view of many clinical successes from the use of histidine in gastric and duodenal ulcer, why is this form of treatment not more generally used? Is it because the patient dreads the use of the needle, and persuades the doctor first to try rest in bed, alkalis, and a milk diet?*

A.—There are, of course, many "cures" for peptic ulcer, including such diverse substances as vitamin A, alkyl sulphates, pituitary snuff—and histidine. Their reputation is due to the fact that peptic ulcer is a remittent disease, and remissions are particularly likely to occur under the influence of psychic stimuli. Unless a new treatment is carefully controlled, it may well appear successful at first. Histidine treatment has by now, however, been very carefully tested in animals and man, particularly in the U.S.A., and there is no case for using it. It is not effective in experimental ulcer in animals. Several well-controlled trials in man have shown that it is less effective than the usual diet and alkalis, and that injections of distilled water give equally good results. Some suggestive work has been done on the inhibition of histamine by histidine, the excretion of histidine in normal pregnancy, and the excretion of histamine in toxaemia of pregnancy (Kapeller-Adler, R., *J. Obstet. Gynec.*, 1941, **48**, 141), but there is no evidence that similar disturbances in metabolism occur in peptic ulceration. Finally, it should be noted that the dose of histidine commonly used in the treatment of peptic ulcer, 0.2 gramme daily, is probably only one-tenth of the normal intake in the food; and that recent American work on young men taking diets in which the nitrogen is provided by amino-acid mixtures rather contradicts the view that histidine is an essential amino-acid in man.

Vitamin K

Q.—*Apart from the prophylactic use of vitamin K in haemorrhage of the newborn, in what other conditions is it of value?*

A.—Vitamin K may be of value in any condition in which the prothrombin content of the plasma is reduced. Deficiency of prothrombin is responsible for the haemorrhagic tendency in jaundice; if this is due to obstruction it will usually respond to vitamin K, but if it is due to parenchymatous disease of the liver it will not. The response to vitamin K may therefore be used as a diagnostic test. The prothrombin level is depressed by the anticoagulant drug dicoumarol, but this action can be reversed in emergency by very large doses of vitamin K—i.e., 100 to 500 mg. A similar but less striking depression of prothrombin occurs during heavy dosage with salicylates, and it has been recommended that 1 mg. vitamin K should be given for every gramme (15 grains) of salicylate. Recently it has been claimed that a high proportion of patients with chronic urticaria show a deficiency of prothrombin and are relieved by vitamin K in a dosage of 2 mg. t.d.s., a.c.

Vaccination and Diphtheria Immunization

Q.—*Is there any practical reason why a child should not be vaccinated against smallpox and immunized against diphtheria on the same day?*

A.—Vaccination against smallpox is usually done some time between the second and sixth months of life, while inoculation with A.P.T. against diphtheria is usually done about the first birthday. It is probably wiser to vaccinate early rather than late, as more severe reactions seem to occur with older infants, and in any case there is a statutory obligation to do so before the child is 6 months old. The question then arises, "Should the infant be given its diphtheria prophylactic at 6 months of age or earlier?" Children under 1 year, even when they receive maternal antibody via the placenta, may develop diphtheria, and there is some evidence that infection in infancy has become more common in recent years. It would therefore seem advisable to begin immunization at 5 to 6 months of age. Now, there is no objection to combining two *bacterial* antigens, since the one does not interfere with the other in stimulating antibody production; but when two viruses are simultaneously injected there may be an "interference" phenomenon, and it is therefore not possible to say if vaccinia would interfere with the stimulation of antibody by the diphtheria antigen. Thus, while there is a case for early immunization against diphtheria, it would probably be wiser to begin the course after vaccination has been successfully completed. It should also be remembered that the child responds less well to antigenic stimuli in early infancy than it does later on, so that the initial dose should be adequate (say 0.5 c.cm. A.P.T.) and a boosting dose should be given 2 to 3 years later.

Iodine for Asthma

Q.—*A man of 54 has been taking Lugol's iodine, 3 drops twice daily for 2 years, as treatment for asthma. He found the attacks much less frequent and less severe during this period and suffered from no side-effects. It was discontinued for six months, but he now wishes to resume the same treatment. Is this desirable?*

A.—Iodine and iodides are of the greatest value in the treatment of asthma, particularly in cases associated with bronchial infection. The only contraindication to their use would be the occurrence of iodism. The usual symptoms of this are nasopharyngeal irritation as from coryza, skin eruptions, nausea, diarrhoea, cachexia, and depression.

Foot-up Position in Shock

Q.—*An accepted practice in cases of shock, especially after haemorrhage, is to raise the foot of the bed. Is there sound evidence that the circulation is better in this position than lying flat? It is uncomfortable in health, and I have found patients so tilted thankful when allowed to resume the horizontal.*

A.—Asmussen *et al.* (*Surgery*, 1940, **8**, 604) showed conclusively that in normal men the cardiac output (Grollman method) and blood pressure were decreased and the pulse rate increased in head-up tilt compared with the horizontal, and in the horizontal compared with a foot-up tilt of 30 or 60°. This was particularly marked if the effective blood-space was increased by reactive hyperaemia, and conversely less marked if the leg blood-space was obliterated by cuffs. Duncan, Sarnoff, and Rhode (*Ann. Surg.*, 1944, **120**, 31) have provided some confirmation of these findings for the smaller tilt used in clinical practice (7.9°) in patients suffering from severe haemorrhage. The mechanism is this: with decrease in blood volume (e.g., after a severe haemorrhage) or increase in blood-space (as in fainting or spinal anaesthesia, due to peripheral vasodilatation), a decrease in venous and right auricular pressure occurs, leading to a fall in cardiac output and blood pressure. In the head-up position, blood is pooled in the veins of the legs, and right auricular pressure decreases further. With the foot-up position, right auricular pressure is increased and blood is drained back to the heart from the veins of the legs, with resultant improvement in cardiac output. If, however, "shock" is due to cardiac failure, or if the heart is already overloaded, as in chronic anaemia, further increase in venous pressure (already above normal) would be harmful. Here, therefore, the horizontal or foot-up position is contraindicated. It all depends, in fact, on what you mean by shock!

Pregnancy and Diabetes

Q.—*Has any recent progress been made towards improving the chances of pregnancy in diabetics, and is one justified in encouraging it in women whose present treatment does not require insulin? Can the existence of diabetes be taken as the main cause of impairment of sexual function—e.g., frigidity—or should one search further?*

A.—The chances of pregnancy occurring in a diabetic woman have been enormously improved by insulin. The question rather suggests that the patient is anxious to avoid insulin and is having an inadequate diet; and if this is the case inadequate treatment of the diabetes may be responsible for the infertility and frigidity. If the condition persists when a diet is given containing over 150 g. of carbohydrate with an adequate caloric value and sufficient insulin to maintain the blood sugar within reasonable limits, further search should be made for another cause of impaired sexual function.

Mastitis and Breast-feeding

Q.—*If a breast goes through the stages of engorgement, mastitis, suppuration, at what precise stage should the baby be taken off that breast?*

A.—There will probably be some diversity of opinion as to the answer to the third part of this question, and in any given case it will always require a nicety of judgment to decide when breast-feeding should be discontinued. Engorgement is not an indication for taking the baby off the breast, but the writer's view is that as soon as there is definite evidence of mastitis (before suppuration occurs) feeding should be discontinued, and so should all manipulations of the breast, which should be put at rest.

Stilboestrol for Suppressing Lactation

Q.—*How much stilboestrol is usually required to suppress lactation? What is the best preparation to use and how should it be administered? If lactation reasserts itself after a course of treatment, what further steps should be taken?*

A.—To prevent or suppress lactation stilboestrol is usually given by mouth, starting with a large dose and gradually reducing over the course of four to seven days. Various schemes of dosage are employed, and in general it can be stated that smaller amounts are required when treatment is begun immediately after delivery than if it is delayed until lactation is already established. If begun early, the following scheme works well: 5 mg. b.i.d. on the first day, 2 mg. t.d.s. on the second day, and then reduce the total daily dose by 1 mg. a day, completing the course in seven days. Alternative oestrogens employed by the oral route are hexoestrol in similar dosage, and dienoestrol in about one-fifth of the above doses. It is said that a single intramuscular injection of 12.5 mg. hexoestrol dipropionate if given within three days of delivery, is sufficient to prevent lactation. For further details see Josephine Barnes (*Journal*, 1942, **1**, 601) and F. Prescott and Margaret Basden (ibid., 1944, **2**, 428).

The breasts sometimes show sign of some activity 24 to 48 hours after completion of the course of treatment. If this is minimal no treatment at all is required. If necessary, however, a further course of stilboestrol can be given, say 4, 3, 2, 1 mg. on four successive days.

Sex Hormones to Control Uterine Bleeding

Q.—*Would you discuss the use of oestrogenic preparations in the treatment of menorrhagia and metrorrhagia? For both these conditions I have been using progesterone, 2 i.u. daily for four days before the expected date of the period, and have had fair success, especially in menorrhagia. Recently a colleague advised that a patient with metrorrhagia, who had been having "periods" which lasted from seven to ten days and occurred about every two or three weeks, should have stilboestrol 1 mg. t.d.s. for four days, starting on the fourth day of the period and repeated whenever irregular bleeding occurred. I cannot see the rationale of this treatment, as surely stilboestrol will only increase the haemorrhage? Recently, on the advice of a colleague, I gave another patient (who began profuse bleeding six weeks after a normal confinement) tab. dienoestrol 0.1 mg. t.d.s.; within two days haemorrhage had ceased. Why should oestrogenic preparations be used in conditions which suggest a lack of progesterone?*

A.—A complete answer to this question would be a lengthy one, and the inquirer should refer to one of the textbooks on sex endocrinology for the details. Briefly it can be stated that functional uterine bleeding is either ovular or anovular—i.e., occurs from an endometrium previously stimulated by progesterone, or, only by oestrogen. Most bleedings take place when the hormonic stimulus is reduced or removed. Progesterone-deprival haemorrhage can be controlled by progesterone but not by oestrogen. On the other hand, oestrogen-deprival haemorrhage can be controlled either by substituting progesterone or by giving oestrogen to raise the blood level again. In practice, therefore, progesterone is usually employed, because not only will it control either type of haemorrhage, but it is more rational in that it supplies the missing hormone and completes the oestrogen-progesterone cycle, thus following the natural sequence of events. However, not all anovular forms of bleeding are due to oestrogen withdrawal; rather they may be due to incomplete stimulation with oestrogen, so the endometrium remains atrophic or only in an early proliferative phase. In such cases progesterone may not control the bleeding, because for it to be effective the endometrium must be well primed with oestrogen. Under such circumstances oestrogen will, however, complete the proliferation and control the bleeding—at any rate temporarily—during the period of its administration.

It is always wise to hesitate to give oestrogen for the control of uterine bleeding, because of its tendency to produce endometrial hyperplasia and to result in further heavy haemorrhage when treatment is suspended. Evidence to show that it is indicated (such as the finding of atrophic endometrium on endometrial biopsy) is desirable before it is given, and even then the dosage should be worked out carefully. Also there is much to be said for continuing treatment after the immediate bleeding is controlled, and to stimulate the natural ovarian cycle by giving first oestrogen and then progesterone over a period of three to four weeks.

Digestive Disorders and Swallowed Sputum

Q.—*Is there evidence that the swallowing of sputum and nasal mucus in bronchial (chronic) patients has any adverse effect on the digestive process?*

A.—The human air-conditioning system is designed on the principle that bacteria and morbid secretions are trapped and directed into the pharynx, whence they are swallowed and sterilized by the gastric secretion. It is probably for this reason that digestive symptoms are conspicuous by their absence in chronic sinusitis and bronchiectasis. When digestive symptoms occur they can usually be explained by pyrexia and the haematogenous spread of toxins. Owing probably to its waxy coating, the tubercle bacillus is more resistant to digestion and more likely to infect the intestine, and the association of gastro-intestinal symptoms with cough should always suggest the possibility of tuberculosis.

Hydronephrosis and Calculus Formation

Q.—*A man of 40 has periodic headache recurring every four weeks and lasting four days. Associated with this are the following symptoms: renal colic, vomiting, blurring of vision, and ptosis of eyelids. He then passes a small calculus about 2 mm. long. This condition has existed for a number of years. The blood pressure is 160/90; blood urea, 30 mg. per 100 c.cm. of blood; examination of the urine shows the presence of calcium oxalate and uric acid crystals. There is slight hydronephrosis of the right kidney, but pyelography reveals no calculus. What further steps of investigation should be taken, and what should be the treatment?*

A.—The presumption is that the hydronephrosis is favouring the formation of calculi, and that the passage of the calculi gives rise to the symptoms. It is also probable that an element of infection is present. The first step should be to have one of the small calculi analysed. If it proved to be uric acid, the uric acid content of the plasma should be estimated; if the level is above normal the patient should be treated as for gout. If the stone is mainly calcium salts, the possibility of hypercalcaemia from a parathyroid adenoma should be considered. If the stone is urate or oxalate, the urine should be kept alkaline, *p*H 6.0 to 7.0, by means of an alkaline diet and an alkaline mixture. With any type of calculus the intake of water should be at least 2,000 c.cm. a day and foci of infection should be removed. To clear up infection of the urinary tract it would be wise to take a small dose of sulphathiazole for a prolonged period—e.g., 0.25 to 0.5 g. t.d.s.

Diabetes and Epilepsy after Meningitis

Q.—*At the age of 6½ a female child developed meningococcal meningitis, which was rapidly cured by sulphapyridine. Eight months later the child was found to have severe diabetes, controlled with difficulty by ordinary insulin and protamine-zinc-insulin. Nine months later the same child has developed epilepsy. Is there any connexion between the three illnesses? There is no family history of either diabetes or epilepsy.*

A.—Epilepsy is not an uncommon sequel of meningococcal meningitis, which would seem to be the case in this patient, in spite of the rapid cure by sulphapyridine. Diabetes does not appear to be recognized as a sequel of meningococcal infection, but the present history at least arouses the suspicion that the infection caused damage to the pancreas.

INCOME TAX

Replacement of Car

P. B. proposes to sell his old car and buy another in replacement. He has had depreciation allowance in past years. What can he claim as an expense?

*** It is presumed that the old car will be sold for a larger amount than its present "written-down" value. In that case no "obsolescence" allowance will be due, and P. B. should claim, not the cost of replacement, but a depreciation allowance based on the cost of the new car.

Taxation of Pensions

W. W. draws a small pension from a public authority by whom he was employed. He states that during his service he suffered deductions from his salary to provide the pension, but paid tax on his salary in full.

*** The pension is undoubtedly liable to assessment to income tax. Deductions from salary to provide such pensions are usually allowed automatically as "expenses." If W. W. did not receive the benefit of such an allowance, he may have a claim to repayment of some tax for recent years.

Voluntary Disposition of Income

A. G. signed an agreement in March last agreeing to pay a certain annual sum for seven years for the benefit of a specified charity. A simple "agreement" is ineffective for the purpose; what is required is a deed under seal. In an attempt to put the matter on the proper legal footing A. G. added the attestation clause appropriate to a deed to the existing agreement and had it witnessed. The income-tax authority points out that the document is stamped as an agreement, not as a deed, and will be effective only as from the date of its execution under seal.

*** We agree, and suggest that A. G. should submit the existing document for stamping. An agreement and a covenant by deed are entirely different legal instruments and the agreement as such is legally ineffective.

LETTERS, NOTES, ETC.

Intravenous Adrenaline

Lieut.-Col. D. C. Macdonald (Farnborough) writes: I have recently returned from Italy and have had no *Journals* since May. In the first one I opened since my return I find an answer to a question on intravenous adrenaline (July 14, p. 73). I do not know who replies to these questions, but his last paragraph is unfortunate, if not indiscreet. He refers to a recent investigation into the use of adrenaline in malaria, the results of which have not yet been published. If he is referring to the investigation carried out in Italy by the R.A.M.C. he will find that the results of this investigation cannot be relied on. Over a year ago I invited first the Allied Control Commission and then the consulting physician A.F.H.Q. to send reliable observers to Palermo to see for themselves the remarkable results obtained by Prof. Ascoli, but, although I made tentative arrangements for accommodation, food, and transport, no one came. There is none so blind as he who does not wish to see. Americans reacted differently. They came, they saw, and they went away convinced that there was something in it. Perhaps your amanuensis would say that they went away with "dust in their eyes," but in America experiments are being carried out with "something more powerful than quinine or atebrin." To quote from their press: "The search for a quinine substitute following Pearl Harbour brought forward atebrin, but the *failure* of either drug to *provide a permanent cure* led to the present procedure." What an admission of failure! When the Conference of Army Physicians, C.M.F., was held in Rome (Jan. 29 to May 3, 1945) I asked permission to speak on the use of adrenaline in malaria; I was allotted *five minutes* as a very great favour and there was no discussion, the chairman simply dismissing the matter in one sentence. I have spoken to more than one medical specialist, and the answer was the same: "I should get 'bowler-hatted' if I carried out Ascoli's method." This, to my mind, was rank cowardice in the face of an enemy that is winning all along the line because our methods are obsolete and futile. Does your correspondent imagine that a man with one of the best brains in Europe would work on this for thirty years if it were completely valueless? What about the works of 150 independent observers written on this same important subject? Do they go for nothing? Would the Italian Army make this treatment compulsory, as it has done, if it were valueless? No, Sir! With one stroke of his little pen your correspondent seeks to wipe out one of the most astounding discoveries of all time. Ascoli will join the ranks of men like Jenner, Pasteur, and many others, who in life were ridiculed by an unbelieving profession but whose works prevailed despite it. The Italian Government has recently set up a Malaria Research Centre in Palermo with Ascoli at the head. Here doctors and students are being trained in Ascoli's technique. Two large malarious tracts of Sicily have been delineated, exactly similar in every detail, and in one malaria will be treated with quinine products only and in the other with adrenaline alone. I should advise the investigators referred to by your correspondent to hold up their report, which might be the subject of ridicule in years to come.

Sleep-walking

Dr. L. J. Bendit (London, W.C.) writes: The recent comments on the treatment of sleep-walking (Aug. 18, p. 241) rather dismay me. They seem to be on a par with treating renal colic with morphine and leaving the calculus where it is. Surely it is time that the profession realized that symptoms like somnambulism are based on psychological trouble and are manifestations of anxiety and hysteria. Thus to "cure" such a thing by making the child step into cold water is simply to ignore the disease and to treat a symptom. The proper way to deal with such cases is in a child-guidance clinic. I may perhaps be allowed to mention a rather dramatic case, where a child of 8 suffered from sleep-walking. The question seemed to resolve itself into finding out what she was looking for in her wanderings. When I had made fairly sure of my ground I told her where babies came from, in such a way as not to embarrass her and so that, if I had missed the mark, she would not be interested. Apparently I had made a good shot: she immediately stopped her nightly peregrinations. Needless to say, many cases are not so simple; nor are they necessarily due to sex traumata. But they are certainly due to anxiety repressed, and this needs psychological treatment, and not either dope or tricks.

Paronychia of Toe

Dr. W. F. Cooper (Kingston Hill) writes: I wrote a note on the use of a file for ingrowing toe-nails, and got reprimanded by one chiropodist who, however, had never had a piece of nail wrenched out. But the case in the *Journal* of Aug. 11 (p. 203) illustrates the advantage. The man wants to continue at work, and he can't do that if he has a piece cut out—it is painful, even if one remains in bed. Filing the middle part will ease pain due to ingrowing nail, and finally abolish the condition; one may be able to file over the pus. One wants a bastard-cut flat file, with safety edge (or second cut); and the safety edge is used to guide the work with a finger. If the safety edge is so used the nail can be abraded right to the skin. May I point out another important detail. The filing is done best when the nail is cold; but if the whole foot is immersed in hot water for some time, as hot as possible, the chitin alters its molecular condition and becomes soft; then one can slit the nail where there is pus, but not cut a piece out, so that any remedy can enter. I should smear the toe well with acriflavine emulsion, cover with one layer of oiled silk, and let him work. He can dress it often, himself. The hot water will help the inflammation. The man's urine is almost certainly acid, and he would do much better if given alkalis with small repeated doses of mag. sulph. until the urine is nearly neutral. I use a universal indicator for this. Addition of phosphates and syrup. ferri phosph. would also do good.

Nocturnal Cramp

Dr. J. Donaldson Saner (Edgware) writes: In answer to the question about nocturnal cramp in legs and feet (Aug. 18, p. 240), I was given a tip years ago by my cousin, the late Alfred Russell, M.D., of Wimpole Street and Devonshire Place, to take a teaspoonful of bicarbonate of soda in water just before going to bed each night. A simple remedy, but it acted like a charm.

Dr. T. L. Crawhall (Watlington) writes: Nocturnal cramp can usually be prevented by a tablespoonful of glucose taken on retiring. I speak from personal experience.

Resuscitation Across a Barrel: Information Wanted

Dr. F. C. Eve (Beverley) writes: Dr. John Yates inquires (July 28, p. 144) if this ancient method is similar to the rocking method. Presumably it is, but I have not been able to find out exactly how it was done. For efficiency, it is now considered necessary to rock 45 degrees each way. Hence the circumference of the barrel should be twice the height of the victim when kneeling. This would demand a barrel about a yard in diameter. One seldom sees so large a barrel nowadays. Can anyone tell me the sort of barrel which would quickly be available on a ship a century ago? Reliable witnesses who have seen this method in use will soon be extinct. I would like to rescue it from oblivion in my booklet, *Artificial Respiration Explained*, now being printed by Messrs. Livingstone. Can anyone kindly and promptly give me facts or references? I do not think it would be nearly so effective as the rocking method.

Dermatitis of Navel

Dr. E. Gallop (London, S.W.) writes: With reference to the question and answer on the above subject (Aug. 18, p. 240), I think that the possibility of ringworm should be kept in mind in this case. I had a similar one that cleared up on applying pigmentum contra tineam of the *Extra Pharmacopoeia*.

Effects of Tobacco Smoking on Health

Dr. Nigel W. Roberts (Cottingham) writes: I welcome the excellent and timely letters from Dr. Lennox Johnston (July 21, p. 98) and Dr. Sybil Tremellen (Aug. 18, p. 233), and I agree whole-heartedly with every word. But it will be of no avail for the medical profession to denounce tobacco addiction so long as so many of the members thereof are themselves addicts, and are, pretty obviously, content to remain so. An ounce of example is worth a ton of precept; it is regrettable to have to record that the worst tobacco-laden atmosphere I ever endure is that of the meeting-place of the local branch of the B.M.A.

Dr. W. A. Bellamy (Waddesdon) writes: Dr. Sybil Tremellen's letter (Aug. 18, p. 233) calls for comment. It contains far too many generalizations to be of any real value as a scientific article. Isolated cases prove nothing; because Winston Churchill is an inveterate cigar smoker and has shown a moral and physical stamina unsurpassed by millions of total abstainers it does not mean that cigar smoking is a panacea for all our ills to-day. The odd cases quoted by Dr. Tremellen prove, as I say, nothing; neither does the fact that I took my company on a "ten-miles-in-two-hours" (in full marching order, three months before my fortieth birthday) on forty cigarettes a day prove anything either.

"Atomic Pregnancy"

Dr. H. G. Howitt writes: A patient told me this morning that she had recently undergone an operation for "a ruptured atomic pregnancy." It is truly amazing to note the rapidity with which the latest scientific inventions are adapted to modern medicine.

Disclaimer

Dr. E. C. Thomas and Dr. Margaret Thomas, of the Edinburgh Medical Missionary Society, writing from the Victoria Hospital, Damascus, wish to disclaim any responsibility for accounts which they understand have appeared in the British daily press describing the recent disturbances in Syria. They have not seen these reports, but learn that their names have been quoted in connexion with the care of casualties.

AND

H. S. PEMBERTON, M.B., F.R.C.P.

(From the David Lewis Northern Hospital, Liverpool)

From the great sequence of workers from Astwood in 1943 to Leys in 1945 there has come a practically unbroken chorus of praise for the good effects of thiourea, thiouracil, and methyl thiouracil in the treatment of thyrotoxicosis ; there are, however, some few (Joll ; Morley, 1944) who are not entirely of that mind. To this more critical view we ourselves would incline, while fully realizing the great value of thiouracil in the treatment of most cases of thyrotoxicosis. We therefore present a series of 29 cases observed and measured by us, mostly over a period of 16 to 21 months, whereas other workers (Nussey, 1944) include some much shorter observations. We believe that this longer period is of great importance, as in several cases we have seen initial improvement, comparable to that obtained with Lugol's iodine, followed by later relapse while still under treatment ; and, in some instances, leading to thyroidectomy.

Our Series of Cases

In all, 29 cases are here studied—8 men and 21 women—the ages varying from 22 to 66 years. The evidence of thyrotoxicosis, suggested by the symptoms, has in each case been supported by a raised basal metabolic rate. The division into primary and secondary types has so much bearing on our main argument that some explanation is necessary : the former have developed their symptoms and signs either before the appearance of a goitre or *pari passu* ; the latter are regarded as secondary to an established goitre, often of years' duration.

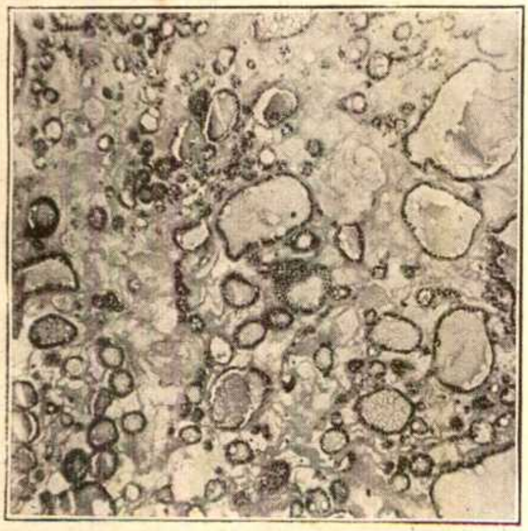

FIG. 1.—Case 14816. Photomicrograph of section of thyroid gland. (× 175.)

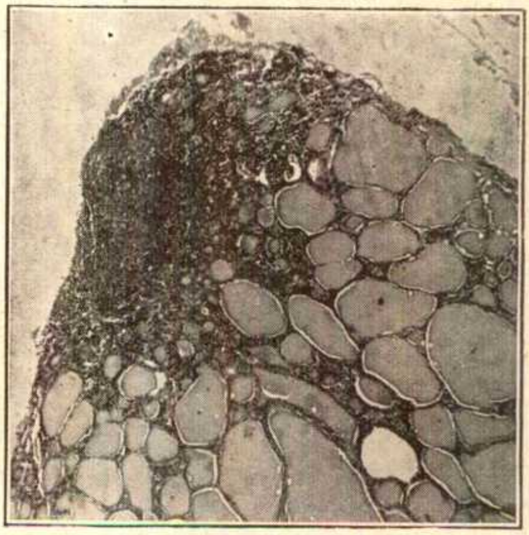

FIG. 2.—Case 14766. Photomicrograph of section of thyroid gland. (× 175.) (Photos by E. L. Murray, A.R.P.S.)

Thiouracil was used almost exclusively—first while the patient was in hospital, until the B.M.R. returned to normal, and then as an out-patient practice. Of the physico-chemical measurements made, initial and end readings alone are given ; in all B.M.R. estimations the Benedict spirometer was used ; blood sugar and cholesterol levels were determined weekly, but we cannot agree with Leys that they are anything like so useful as the B.M.R. as a guide to the degree of thyrotoxicosis. Our usual dosage of thiouracil has been 0.5 g. twice daily until the B.M.R. began to return to normal limits ; then 0.2 g. daily or twice daily ; and finally 0.05–0.19 g. as a maintenance dose. The figures given (see Table) of the time under treatment refer only to the actual days on which the patient took the drug and do not include periods of investigation or of rest (often lasting for weeks). From this table of results the following broad inferences have been drawn.

Improvement was noted in 22 cases, irrespective of sex and age but not of duration ; the tendency was, the longer the history the less the effect of thiouracil. Of these 22 cases, 12 could be classed as much improved, mainly in a clinical sense, although there was a corresponding march in physico-chemical changes, most notably in B.M.R. Three cases were so little improved as to require thyroidectomy, and in all three it will be noted that the thyrotoxicosis was of secondary type. Of the 21 primary cases recorded above improvement occurred in 19 ; of the 8 secondary cases, improvement took place in 2 only.

Effects on the Thyroid Gland

Enlargement.—In those cases with marked goitre further enlargement of the thyroid gland was noted after the 7th day—which constituted the peak period—afterwards declining to a size somewhat above that before treatment. In one case (No. 26) the neck enlarged from 31.4 cm. to 36.2 cm. and remained at that girth long after all symptoms had gone and physico-chemical measurements had returned to normal.

Microscopical Appearance.—In 2 cases we have had an opportunity of examining sections of the thyroid gland removed at operation, undertaken because of the failure of response to thiouracil. Photomicrographs (Figs. 1 and 2) are here shown, and the pathologist (C. V. Harrison) reported as follows :

" 14816.—Macroscopically, the thyroid was enlarged and nodular, and showed plentiful colloid. Some of the nodules showed signs of

degeneration. Microscopically, the gland is broken up into nodules by fibrous bands, but lymphocytic infiltration is minimal. The acini are variable in size, but are all in a resting stage with colloid storage. There is hyaline degeneration in the stroma between the acini.

14766.—Macroscopically, the gland was enlarged and nodular and contained plentiful colloid. Microscopically, the gland is broken up into nodules by bands of fibrous tissue. It shows quite numerous foci of lymphocytic infiltration, many with germinal centres. The thyroid acini are mostly enlarged and filled with colloid, and show a resting epithelium; only a few showed any signs of hyperplasia."

From the work of Moore *et al.* (1944) at the Massachusetts General Hospital on 34 cases treated with thiouracil as a pre-operative drug we know that the most prompt clinical response occurred in those patients whose thyroids, on histological examination, showed marked hyperplasia with a low colloid content. It is interesting to observe that those two cases of ours which responded badly to thiouracil both had thyroids in which involutionary changes predominated over hyperplasia.

Toxic Effects of Thiouracil

Symptomatic.—Although nausea and occasional vomiting were experienced in the earlier cases treated by us with thiourea, we have not seen this occur with thiouracil. The chief symptoms noted have been vasomotor—faintness, flushing, and vague muscular pains in the chest, head, and neck.

Granulocytopenia.—Nearly every case we have treated has shown an absolute granulocytopenia (of varying degree) with relative lymphocytosis, usually from the 7th to 10th day. When the white count falls to around 4,500 per c.mm. (with lymphocytes over 40%), cessation of the drug for 3 to 4 days is usually enough to cause the count to return to normal, and when this occurs the drug can be started again without untoward effects.

Agranulocytosis.—Only one of our cases (No. 18) developed a true agranulocytosis, although two others (Nos. 12 and 24) developed such severe neutropenia as to warrant active therapy. The striking fact in this case was the rate of development of the agranulocytosis; although blood counts were done on alternate days, the white count fell to *nil* in 24 hours. The cause would appear to be overdosage rather than a personal idiosyncrasy; because this girl began again with her thiouracil and has since had 20 g. without ill effects. This case is also of interest because the patient developed her agranulocytosis 23 days after treatment—contrary to Himsworth's general rule that such cases usually develop during the first 14 days. In all three cases extract of yellow bone-marrow given by mouth was found to be of most value in restoring the white count to normal.

Purpura.—Severe thrombocytopenic purpura has been described by Newcomb and Deane (1944). One of our cases, that of a female diabetic aged 58, developed a marked purpuric rash after 18 days' (16.5 g.) treatment with thiouracil. The blood picture was as follows: thrombocytes, 360,000 per c.mm.; coagulation time 5½ minutes; bleeding time, 9 minutes; Hess's test strongly positive. The condition abated on cessation of the drug.

Drug Fever.—St. Johnston (1944) has reported 3 cases of drug fever in his series of 7 cases treated with thiourea. In our series we have had one such case (No. 16). This patient, after 8 days' therapy (14 g.), began to complain of headache, nausea, painful glands in her neck, and sore mouth and eyes; her temperature rose to 102.2° F. and her pulse to 124. Her face was flushed, with numerous small white blebs over both cheeks, her eyelids were red and swollen, her mouth showed many small white ulcers, her submandibular and axillary glands were large and shotty; there was no splenomegaly; the skin over her thorax and abdomen had a fine maculo-papular rash. Her white count at this time was 7,400 per c.mm., of which polymorphonuclear cells were 68%, lymphocytes 17%, monocytes 2%, and eosinophils 13%. On cessation of the drug the symptoms abated, but on starting again—on two separate occasions—the signs and symptoms returned. This case differs from those described in showing ulceration of the mouth, eosinophilia, and absence of both splenomegaly and neutropenia.

Other Rashes.—Several of our cases have shown rashes, which were of two main types—maculo-papular, as in the woman described above, and scarlatiniform (Case 26).

Effects of Thiouracil in Cases Other than of Thyrotoxicosis

Hypertension and Diabetes Mellitus.—On the basis of reduction both of blood pressure and of blood-sugar level in cases of thyrotoxicosis, we measured the effect of thiouracil on a group of cases suffering from these conditions. Six cases of essential hypertension were treated for varying periods with little or no response. Its value in diabetes is also disappointing, although we found that its use in diabetes with mild thyrotoxicosis allowed of a reduction in the amount of insulin formerly required.

Cardiac Failure.—Blumengart *et al.* have suggested subtotal thyriodectomy in severe cases of cardiac failure, on the assumption that by reduction of B.M.R. the work of the heart is diminished. On this principle we tried to decrease the activity of the thyroid in two cases of cardiac failure; one case was treated for 30 days (22 g.) with no apparent improvement. We reached the conclusion that thiouracil is of value only in those cases of cardiac failure which have a thyrotoxic basis. Cases of auricular fibrillation of thyrotoxic origin may be controlled by thiouracil with a return to a normal rhythm; this was seen in Cases 1 and 19.

Myxoedema.—In an attempt to discover the mode of action of thiouracil we gave it to a patient with myxoedema. She received 26 g. in 26 days. There was no change in her blood sugar or cholesterol levels, her B.M.R. rose from −40% to −37%, and she lost 4 oz. in weight.

Summary

Of 29 cases of thyrotoxicosis treated with thiouracil improvement was noted in 22, while 12 were classified as much improved.

Of the 21 cases of primary type, improvement was noted in 19, and of the 8 secondary types in 2 cases only.

The effects on the thyroid gland are discussed and photomicrographs after thyroidectomy shown.

Toxic effects are discussed.

The effects of thiouracil in cases other than thyrotoxicosis are recorded.

Our thanks are due to Messrs. Ward, Blenkinsop and Co. for their generous supply of thiouracil in the early days, and to Dr. C. V. Harrison for his reports on the sections.

THE ROLE OF ANIMAL-TYPE DERMATOPHYTES IN HUMAN RINGWORM

BY

BERNARD A. THOMAS, M.D., B.Sc., D.P.H.
(Department of Dermatology, Royal Infirmary, Cardiff)

MARY LENNOX, M.B., B.Ch., B.Sc., D.P.H.
Deputy Medical Officer of Health, Borough of Barry

AND

J. T. DUNCAN, F.R.C.S.I.
(Emergency Public Health Laboratory, Winchester)

A feature of dermatology in recent years has been the increased incidence of fungous diseases. Attention has been drawn to the fact that ringworm infections in particular are seriously increasing (Ingram, 1944) and that ringworm of the scalp, which had become a comparatively rare disease, is again threatening to attain epidemic proportions.

Comment has never been lacking on the association of ringworm in man with animal contacts and on the finding of "animal-type" fungi in human lesions. Possibly because it is not always easy to trace the infection from animal to man, this association has been presented in the light of an uncommon occurrence. It is our belief that the importance of the animal source of infection in human ringworm has been insufficiently stressed in this country, and that animal infections occur far more often than is commonly supposed. The mycological findings in ringworm specimens submitted to cultural methods of investigation show a high proportion of fungi hitherto considered unusual in human lesions, especially in ringworm of the scalp, and suggest either that we are witnessing an increase in the incidence of ringworm in man caused by dermatophytes usually parasitic on the lower animals, or that infection by these types of dermatophytes has in the past been incompletely assessed.

In a consideration of the epidemiology of ringworm a distinction is drawn between tinea circinata and tinea tonsurans. A survey of the literature shows that, in the former, animal sources of infection have been recognized from time to time; but in the case of tinea tonsurans the connexion appears not to have warranted any detailed consideration. Kinnear (1931) reported that the occurrence of infection of the scalp with microspora other than *M. audouini*, was very rare in this country. Ashton (1932), investigating the frequency of ringworm in cattle, concluded, after interviewing nearly 400 insurance practitioners, that ringworm derived from animals was not uncommon in certain districts, but chose particularly the glabrous skin rather than the scalp. More recent English publications (Roxburgh, 1944; Shanks, 1944) advocate treatment of tinea tonsurans only by *x*-ray epilation, and, except for suppurative cases, make no mention of the conservative method, which is permissible where the causative organism is an animal type.

The prevalence of the different types of pathogenic fungi is known to vary from country to country and, indeed, from locality to locality. Sabouraud was at pains to emphasize the frequency of animal-type infections in ringworm subjects in France. In the United States the importance of animal types of fungi has for long been realized. The practical significance of these epidemiological considerations was recognized by Lewis and Hopper (1937), who correlated and confirmed the findings of earlier American workers (Bloch, Jadassohn, Miescher, etc.). These had suggested that scalp infections caused by microspora pathogenic to animals are curable by topical methods alone. The topographical variability in the United States is well described by Wise and Sulzberger (1938). They point out that when one considers that in the west and south-west States almost all mycotic scalp infections are due to the "animal-parasite" fungus *M. lanosum*, while children in the cities of the eastern seaboard are mainly affected by *M. audouini*, the human form, it becomes at once comprehensible that the results of various types of prophylaxis, therapy, etc., must be completely different in different parts of the United States.

The role of *M. felineum* as a cause of ringworm in children has been investigated in Canada by Davidson and Gregory (1933). In a study of ringworm in Winnipeg they isolated species of microsporum from 75 children, 43 being *M. audouini*, and 32 *M. felineum*. However, as 19 of the *M. audouini* isolations were from a single school outbreak, the authors considered that a fairer impression of the relative importance of the two species, in the area, would be given by a quotation of the number of outbreaks caused by each. These were: *M. audouini* 14, and *M. felineum* 24.

To attempt to estimate the incidence of animal-type ringworm in Great Britain is no easy matter, and one is forced to the conclusion that not enough evidence is obtainable from published records to support any dogmatic statement as to the relative frequency of the human and animal types. Sabouraud (1910) stated that the earlier English observers had not controlled their microscopical examinations by cultures. He asseverated that animal microspora were not rare in England, it being probable that the cases of tinea circinata ascribed by Adamson and others to *M. audouini* were in fact caused by animal dermatophytes.

Fox and Blaxall (1896a, 1896b) were the first workers to demonstrate the transmission of cat ringworm to man. They recovered *M. felineum* from 14 cases of ringworm, and were able to trace the infection to 11 separate sources.

Generally speaking, little has been done by culture-tests to determine the types of ringworm fungi in Britain, apart from some local investigations. Tate and Hare (1928) examined specimens from L.C.C. schools and found *M. audouini* to predominate. Smith (1944) refers to the oft-quoted figure of 90% as representing the incidence of *M. audouini* in cases of tinea tonsurans. We have reason to believe, however, that infection by animal types of microspora is now much more frequent than this figure suggests. Duncan (1945) isolated 265 cultures of dermatophytes from unselected cases of human ringworm in various parts of England and Wales, but chiefly in the southern counties, and found that 58% were types usually parasitic on the lower animals. The genus *Microsporum* was represented by 211 cultures, of which 122 (57.8%) were of animal types (*M. felineum*, 74; *M. lanosum*, 48) and 89 of the human type (*M. audouini*).

Animal Contagion

Most of the common domestic animals have at different times been suspected of imparting ringworm to man. With animals, as with man, it is the young that are most susceptible to infection. *Calves* have probably been most often implicated, especially on the European continent, and it was in relation to them that the transmission of ringworm from animal to man was first described. In 1840, contemporaneously with an epizootic of ringworm among cattle, almost the entire population of the Swiss village of Andelfingen was known to have ringworm. A smaller outbreak was recorded in 1925 at the cattle-testing station at Pirbright, in this country. Despite specific precautions, five attendants were infected from diseased cattle. Ashton (1932) reached the following conclusions, *inter alia*, regarding ringworm in man.

1. It is the trichophyta rather than the microspora that are commonly communicated to man from cattle.
2. Young stock animals are chiefly involved.
3. Dogs and horses are also susceptible, goats and cats more rarely.
4. Direct contact with the animals or with posts, etc., they have rubbed against is the usual method of transmission.
5. The disease is often limited to the arms and forearms.
6. The prognosis is good and spontaneous cure may occur.

At the present time, while sporadic cases from calves are being constantly encountered, cattle ringworm does not present a problem of urban districts or a source of institutional outbreaks.

Grooms, farriers, and others were formerly often infected from *horses*. As in the case of cattle ringworm, in which adult males are the victims of contagion, tinea barbae is a typical manifestation of the affection. More modern methods of locomotion have rendered the horse an unimportant focus of ringworm infection nowadays, but it used to be otherwise. Tilbury Fox (1871) described an outbreak of ringworm involving seven men, who had received their infection from a pony, but even in those days this plurality of victims was considered exceptional. Bunch (1901) was able to demonstrate cultural proof of connexion between two cases of human ringworm and their equine sources.

A *cat* was proved to be responsible for the biggest recorded "epidemic" produced by one animal. Roberts (1909) described how a kitten brought from Egypt communicated ringworm to 13 persons and another cat directly, and to a child and a dog indirectly. It was found possible to take specimens for culture from all those infected, and the same species of microsporum was isolated in each case. There is no dearth of evidence incriminating the cat in smaller outbreaks and sporadic cases. It is interesting to note how frequently a stray kitten has been taken into a household just before the occurrence of a case of ringworm in that house.

Whereas no textbook omits to refer to canine hosts, the friend of man seems to have been neglected in attempts to provide direct cultural connexion with human ringworm. Sabouraud *et al.* (1908), in their work identifying *M. lanosum* with *M. canis* (Bodin), noted that a particular character of this microsporum is that it often gives rise to family epidemics. They instance an outbreak, in a family of six persons, all with ringworm lesions. *M. lanosum* was recovered from five of the cases; the sixth was not seen. As to the source of the epidemic, they stated that a dog was accused, without proof, of this family outbreak. More recently in France, Stevenin (1937) has recorded three cases occurring in veterinary students; *M. lanosum* was found on culture in each case, but it was not possible to trace the infection to a particular animal. In England, Bunch (1901) included a terrier in his series, showing that the dog was infected with the same organism as he recovered from a case of kerion.

Our own experience in this respect is considered worthy of record. We have recently encountered an epidemic in which an adult and four children, directly, and four children and a cat, indirectly, were infected from a puppy (Table I). Conclusive cultural evidence as to the essential unity of the outbreak was forthcoming in the cases of the eight children and the dog. Hull (1941) has averred that most reported cases of transmission between man and animals are open to criticism, as they are based on slim circumstantial evidence. Accordingly, we have made every effort to obtain direct evidence, where possible. The affected adult was unwilling to submit to examination, and the cat, domiciled next door, was destroyed after a diagnosis of ringworm had been made independently by a veterinary surgeon. Cases 1, 2, and 3 (Table I) were the children of the one adult concerned. All the patients lived in three neighbouring streets, in a part of the town which is known as the "Island" but which is, in fact, a peninsula separated from the main town by a causeway some 200 yards long. They all attended the same school, four of the girls being in one class. The puppy had been recently acquired, and was observed to be in what was described as a "mangy" condition when bought. No child had any skin lesions before the purchase of the animal, and we have not been able to trace any case of ringworm on the Island for at least 12 months previously. The puppy was a mongrel of uncertain origin and age. Inspection revealed gross involvement of its skin, the trunk being almost devoid of fur and the limbs and head only sparsely covered. The denuded areas were layered with an abundance of large flaky scales, which were easily detachable.

TABLE I.—*The "Island" Epidemic*

Case No.	Age	Contact	Condition	Lesions
1	8	Puppy	(a) Tinea circinata	(a) Twelve scattered circular scaly patches, about 1 cm. in diameter, on face. Multiple similar patches on chest, with uniform papulation. Limbs liberally covered with small papular and pustular microsporides.
			(b) Tinea tonsurans (developed subsequently)	(b) Patch, 1·5 cm. in diameter, in occipital region, almost devoid of hair and showing slight scaling
2	13	,,	Tinea circinata	Multiple minor healing lesions on face, neck, arms, and left thigh. On the right thigh a large fresh circular patch, papular and mildly erythematous
3	10	,,	,, ,,	Five discrete circular lesions on face. Diffuse scaling on neck. Multiple scattered papular microsporides on limbs. Large solitary patch on front of chest
4	10	,,	,, ,,	Eight discrete circular lesions, ½ cm. in diameter, on face, neck, chest, and arms
5	12	Case 2	,, ,,	Solitary raised circular patch with red papular edge and healed scaly centre on inner side of right upper arm
6	6	?	Tinea tonsurans	Circular patch, almost denuded of hair and covered with thick scales, in occipital region
7	11	Case 3	Tinea circinata	Red scaly lesion on right arm, 2·5 cm. in diameter, and with slight peripheral vesiculation
8	10	,,	,, ,,	One circular scaly lesion, 2 cm. in diameter, on thigh. Small peripheral papules

The causative organism in all these cases was found to be *M. lanosum*. In order to trace the subsequent course of the outbreak and to investigate the possibility of another focus of infection, all cases of suspected ringworm occurring in the immediate locality since, and also further afield in the area, have been examined and specimens taken for culture. It is a fact that, in 21 positive cultures over a period of eight months, *M. lanosum* has not once been found, though *M. felineum* has been frequent.

The subsequent unselected cases, 45 in all, yielded interesting information when specimens from them were submitted to culture. Table II shows the results in the 21 positive cultures, and otherwise includes only the two instances of simultaneously affected siblings, in one of which no specimen was obtained for culture and the other giving a negative finding. The large preponderance of animal-type dermatophytes in all these sporadic cases is at once apparent.

TABLE II

Case No.	Age	Condition	Contact	Organism	Type

Opportunities of examining the animal suspected of being the source of the various infections, by means of Wood's light, etc., have not often presented themselves, and obviously the majority of patients are able to describe some household pet. But we regard the frequent association of kittens and other young animals with cases of ringworm as more than coincidental. In Cases 15 and 16, for instance, the destruction of their kitten because of a "diseased" coat, following the onset of these two cases, is unlikely to be fortuitous; and in Case 20 the patient, a slaughterman, explained that a few days previously he had dressed a calf's carcass, the coat of which had "alopecia." A colleague of his was said by him to be similarly affected.

Specimens from 22 patients gave negative results. Of these, 12 were on clinical examination considered to be probably ringworm. One girl—clinically our most certain case of ringworm—possessed two Persian kittens, which are reputed to be particularly susceptible to ringworm. Another possessed a recently acquired kitten, and a third a puppy.

There remained 10 cases, which had specimens cultured on the off-chance of their yielding a ringworm fungus, but which were probably not ringworm. Only one of these subjects possessed a kitten. Thus, quite apart from the Island cases, close contact with young animals was found in 12 out of 35 cases of proved or probable ringworm. No pretence is made that statistical significance can be read into such small numbers, but they do tend to confirm the suggested infectivity of young animals, already referred to.

Two other points must be borne in mind when assessing the importance of animal contagion. On the one hand, older animals may play some part in the transmission of infection. Sabouraud *et al.* (1908) found that the average age of 15 dogs with ringworm was 23 months. On the other hand, animal-type fungi can be transferred between human beings, but opinions differ as to the proportions thus communicated. Lewis and Hopper (1937) point to this facility of transmission from man to man as a method of distinguishing between animal and human types of infection. Thus the ease with which human types pass between human beings, and animal types between animals, is in contrast with the smaller risk of contagion from man to animal and animal to man. This fact is borne out in our Island series. The four primary cases were all grossly infected, the four secondary cases showed only solitary lesions, and we have been able to trace no transmission from these to tertiary cases. Obviously the profusion of the pathogen accounts for the severity of the directly infected persons. The areas of their bodies affected were chiefly the chin, the neck, the upper part of the chest, and the front of the forearms—i.e., the areas of contact with the puppy when they nursed it, as apparently was often the case.

Nature of Lesions

As regards the glabrous skin, the wide variability of the lesions has often been described. As long ago as 1871 Tilbury Fox pointed out that ringworm of the surface varies considerably in aspect, from a mere desquamating erythema to a pustulating surface resembling, and apt to be mistaken for, eczema, there being many transitional herpetic forms. In his pony cases the severity of the lesions was considered to depend on the profusion of the fungus implanted on the skin, and our puppy cases correspond with this. Despite the variability in clinical appearances, the typical ringworm patch—circular, faintly erythematous, with central scaling and peripheral papulation—was most frequently encountered.

Infection with animal-type fungus is considered to produce more inflammatory lesions on the glabrous skin, to be more resistant to treatment, and, as already mentioned, to be less contagious. No great difficulty is experienced in clearing up the smaller solitary lesion of either animal or human type, but the severer infections, in which microsporides are present, may prove refractory. The time taken to cure the four primary puppy cases varied between five and ten weeks.

The clinical appearances in ringworm of the scalp often make it possible to distinguish between animal and human types of infection. The classical description of tinea tonsurans met with in the various textbooks applies particularly to those cases in which *M. audouini* is the pathogen. The typical patch shows as a greyish and scaly area, with hairs broken off to about one-eighth of an inch. These stumps have lost their elasticity and, being bent in different directions, have an appearance described as "stubbled corn." Erythema is not marked, there is rarely swelling, and oedema and pustulation are absent. The patch may increase in size to involve almost the whole of the scalp, but will be found to have a clear-cut circumscribed growing edge.

Generally the animal types of infection produce an inflammatory appearance. The skin is reddened, often swollen, almost devoid of hair, and occasionally surmounted by pustules, without necessarily reaching the grossly suppurative condition known as kerion. The few remaining hairs are easily removed with forceps. Exceptions to this general description are met with, and in the two *M. lanosum* cases (Nos. 1 and 6) erythema was entirely absent. Yet these two children, whose parents refused treatment, went on to achieve a spontaneous cure. Multiple patches have been commoner than single ones in these animal-type cases. The larger patches sometimes evidence pustulation, while the smaller lesions in the same case may be erythematous only.

Treatment

The treatment of tinea circinata merits no special description. The number of fungicidal preparations is legion and most of them are effective. We have found, for routine treatment, that Whitfield's ointment is quite efficacious, and we have not had recourse to the more elaborate proprietary remedies.

It is in cases of tinea tonsurans, however, that the importance of distinguishing between human and animal types finds its greatest application. In the former group epilation by means of x rays is the method of treatment that holds pride of place, and its value is indisputable. Many consider that thallium acetate should no longer play a part in the treatment of ringworm of the scalp, and the Ministry of Education does not sanction its use. There are also objections, however, to the use of x rays, and the following may be mentioned.

1. There may be failure of re-growth. Shanks (1944) reports that, with modern apparatus and accurate dose calibration, these accidents are now rare. With less skilled workers the number of cases of permanent alopecia rises.
2. A period of some five to six months is required before a full growth of hair is obtained, and the more sensitive children, especially girls, object to returning to school at the end of one month after treatment, which is the minimum time in which they may be allowed to do so.
3. Apparatus is not everywhere available, and, particularly under present conditions, treatment is unobtainable in some districts.
4. X rays are unsuitable for very young children.

The group of scalp infections attributable to an animal dermatophyte differs from the human type in being amenable to treatment by topical measures alone. In this country it had been usual to restrict these conservative measures to suppurative cases. Of the nine cases of animal-type scalp ringworm (Table III), four at some stage showed evidence of slight pustulation, and five were non-suppurative. As previously mentioned, two of these underwent spontaneous cure in eight and thirteen weeks respectively. The remainder received topical treatment and were cured in periods varying from four to eight weeks, but it was not considered that these times were minimal. Cure was assessed by negative response to Wood's light, negative result to direct microscopy, and, in one doubtful case, negative culture, all treatment having been discontinued for seven days. On the affected patches new hair grows slowly and does not keep pace with the re-growth of the rest of the scalp.

TABLE III.—*Tinea Tonsurans Cases*

Case No.	Organism	Mode of Cure
1	M. lanosum	Spontaneous
6	"	"
11	M. audouini	X-ray epilation
12	"	" "
14	M. felineum	Conservative
15	"	"
17	"	"
18	Probably M. felineum	"
19	M. felineum	"
21	T. asteroides	"
26	M. audouini	X-ray epilation
27	"	" "

The routine treatment adopted was similar to that described by Sutton and Sutton (1941) as follows:

1. Close clipping of the hair over the whole scalp.
2. Daily shampoo with ordinary soap.
3. Epilation of hairs from the affected patches and from a narrow margin around the patches, the hairs extracted being carefully burned.
4. Application daily of an ointment containing 6% precipitated sulphur and 4% salicylic acid. This may be rubbed into the lesions so long as no untoward reaction is observed.
5. The wearing of a clean linen cap, which should be renewed daily.

The willingness of the parents to co-operate in this somewhat elaborate toilet had previously been doubted, but with the exception of the two cases in which they refused any treatment, their response was surprising and gratifying. Their aim was to get the child back to school in the shortest time.

Discussion

It is apparent that the type of infection has considerable prognostic significance, and that the lesions produced by dermatophytes pathogenic to animals are those likely to be cured spontaneously or without great difficulty. It has been indicated that, of the human type of fungi, *M. audouini* is very resistant to treatment and is a common offender in this country, but it must be noted that Livingood and Pillsbury (1941) have shown that even *M. audouini* infections have occasionally been known to heal spontaneously, sometimes before puberty, if left long enough. Much less common, but even more resistant to treatment, are the endothrix trichophyta (e.g., *T. tonsurans*, *T. sabouraudi*). The ectothrix trichophyta (e.g., *T. asteroides*), representing animal infection, while producing more violent local inflammatory reaction, are easily amenable to treatment.

In the United States, Lewis and Hopper (1943) go a stage further in their adherence to conservative methods of treatment. They divide their scalp ringworms into resistant and non-resistant groups of infection. The non-resistant cases are those which respond to local therapeutic measures, and include not only those produced by animal dermatophytes but also those human-type infections which produce, among other symptoms, markedly inflammatory reactions. In the resistant group such simple measures are unlikely to succeed. Nevertheless even here manual epilation under filtered ultra-violet rays, followed by the application of adhesive plaster, has, in their experience, been found adequate treatment for some small patches of tinea tonsurans.

From the preventive aspect attention should be paid to animals which are likely to be infected with ringworm. It may be difficult to get a patient to part with his pet (the Island puppy still lives), but he can be induced to consult a veterinary surgeon, and treatment of the animal instituted. Wooldridge (1934), advocating the use of Wood's light by veterinary surgeons, makes it clear that a careful search is indicated before absolving an animal from a charge of ringworm. He points out that in the cat there may be no loss of hair, and that the small size and general hidden character of the lesion, coupled with the fact that there is little irritation, may result in its being easily overlooked even on close inspection. It would be advantageous if the introduction of kittens, particularly stray ones, into a community of children could be preceded by such an examination. As a further precaution, animals belonging to households containing ringworm should not be sold or allowed their freedom.

Finally, the advantage of cultural methods in diagnosis, which provide the only means of identifying the species of the infecting fungus, must be obvious to all, and they should be used whenever practicable. In the borderline cases, where there is no clinical indication as to the type of infection, it is submitted that the patient should be given the benefit of the doubt and only conservative treatment undertaken. Culture on a larger scale will eventually give valuable information as to the organism predominating in a particular area, and knowledge of this will be a further pointer in diagnosing between animal and human types of infection.

Summary

The position of ringworm infection with animal-type dermatophytes in this country is reviewed.

Well-authenticated cases of the transmission of ringworm from animal to man are described.

An account is given of a recent particular outbreak in which five persons directly and four persons indirectly were infected from a puppy, the association being proved by cultural investigation.

Some 20 subsequent cultures, taken from patients in the same area, are discussed and the type of organism given.

Clinical findings are described.

Treatment of tinea tonsurans is discussed, and stress is laid on the importance and practicability of treating by conservative methods scalp ringworm produced by animal-type fungi.

Our grateful acknowledgments are due to Dr. E. I. Davies, medical officer of health to the Barry Borough Council, for permission to publish details of the majority of cases dealt with in this article; also to Mr. Walter Wathan, chief clerk in the Public Health Department of the same authority, for the very willing clerical services he has afforded us.

NERVE INJURIES IN CHILDREN

BY

H. S. SOUTTAR, C.B.E., M.Ch., F.R.C.S.

Injuries of the peripheral nerves in children are fortunately rare, but when they do occur they present certain peculiarities so unexpected that it appears worth while to describe two recent cases. Both were injuries of the deep branch of the ulnar nerve due to deep penetrating wounds by glass fragments, in both suture was undertaken after healing of the original wound and the full establishment of degeneration and paralysis, and in both recovery was rapid and complete.

Case I

Mary S., aged 10, was referred to me by Dr. Riddoch with the history that six months previously she had fallen while holding a glass vase. The glass broke and penetrated the palm of the right hand, just below and lateral to the pisiform bone. A small healed scar showed the point of entry. Sensation was normal, but there was complete paralysis of all the muscles of the hand supplied by the deep branch of the ulnar nerve; Froment's sign was present.

Through a curved incision, lateral and distal to the pisiform, the deep structures of the wrist and palm were exposed. The main trunk of the ulnar was first identified and the cutaneous branch seen to be intact. On following the deep branch it was found to be completely divided, ending in a small end-bulb. The distal portion, also with a small bulb, was found with ease, and after removal of the bulbs suture was effected with very fine catgut. Healing was normal, and ten months later recovery of all the small muscles appeared to be complete and the function of the hand normal. At the time of operation the great size of the nerves and the facility of suture were remarked.

Case II

John M., aged 6, was cut by glass in an air raid, a wide deep wound extending across the inner border of the right hand just below the wrist. A large deep scar remained. Sensation was lost in the ulnar area of the hand and there was paralysis of all the small muscles supplied by the ulnar nerve; Froment's sign was present.

It seemed doubtful if in such a small hand suture could be effected, but on exposing the tissues in front of the wrist the ulnar nerve was found to be of almost adult size and quite out of proportion to the other structures. The deep and superficial branches were followed with ease and both were found to be completely divided, ending in bulbs. The distal portions were found without difficulty and suture of each was effected in the usual manner. A year later there was complete recovery both of sensation and of movement, and the function of the hand appeared to be perfectly normal.

Commentary

These two cases give rise to several curious observations. It would appear that the peripheral nerves in a child are out of all proportion to the other structures, and indeed approach adult dimensions. On reflection it is what one would expect on developmental grounds, since the nerve cells are almost unique in their individual persistence throughout life, but, so far as I am aware, the fact has not been recorded nor its surgical importance appreciated. The discovery of even small nerves among the minute structures of a child's hand is thus easy. Their rapid recovery is to be expected from the superior vitality of a child.

Complete recovery after suture of the ulnar nerve is very unusual, if it ever occurs, but this is due to the fact that it is a mixed nerve, and not, as has been suggested, to the smallness and delicate function of the muscles it supplies. The deep branch is a purely motor nerve, and with it one may reasonably expect complete recovery, as occurs after suture of other purely motor nerves such as the posterior interosseous and in a great degree the musculospiral.

In such small hands the diagnosis of a nerve injury is not easy and Froment's sign is invaluable. The best way to elicit it is to pull on a card with the finger and thumb of both hands. Normally the powerful adductor muscle of the thumb is used and the thumb remains flat, but in ulnar paralysis this muscle is not available and an attempt is made to replace it by using the long flexor. This, however, flexes the terminal joint of the thumb, producing Froment's sign. A sign which can be recognized by the patient himself is of real value, particularly if its disappearance is associated in the infant mind with the hope of financial reward.

It is hoped that these experiences may encourage others to deal with an injury which if untreated has such grave consequences to the patient and which at first sight appears to involve difficulties which one might well regard as insuperable.

SCIATIC "NEURITIS"

BY

J. MacD. HOLMES, M.D., M.R.C.P.
Physician, Staffordshire General Infirmary; Consultant Physician, Wrexham and East Denbighshire War Memorial Hospital

AND

B. R. SWORN, M.B., F.R.C.S.
Surgeon, Staffordshire General Infirmary

It is now generally accepted that the commonest cause of chronic pain in the distribution of the lumbo-sacral nerve roots is a rupture of a lumbar intervertebral disk, but there has been much discussion during the past few years between the exponents of the "disk" and "neuritis" theories of the causation of lumbo-sacral root pain. For instance, Dandy (1943) believes that, apart from tumours of the cauda equina and bony disease of the spine, sciatic pain is invariably caused by a ruptured disk or a "concealed" disk. Symonds (1943) has stated that "the vision of an inflamed and swollen sciatic nerve, so confidently stated to be the cause of the syndrome in question, has never yet been granted to human eyes." On the other hand, Bankart (1943) has expressed the opinion that "neuritis" is the commonest cause of sciatica. He believes that the neuritis arises from a spread of periarticular inflammation in spinal arthritis to the nerve roots in the intervertebral foramina.

It seems clear, from reading the voluminous literature on the subject, that much of the variation in opinion of different authorities, neurological and orthopaedic, is due to lack of a common definition of the term "sciatica." If the diagnosis of "sciatica" be applied less loosely to cases of posterior crural pain and used only when there is evidence of a lesion of a lumbo-sacral nerve root we believe that a much more accurate clinical classification will be possible. This narrowing of the definition to "lumbo-sacral root pain" is particularly valuable when surgical treatment may be contemplated, and has previously been suggested by Pennybacker (1942).

Since we treated our first cases of ruptured lumbar intervertebral disk in 1938 we have modified our original views on the frequency of this lesion as a cause of chronic lumbo-sacral root pain, but we are in agreement with those who state that it is the commonest cause of the syndrome. In a series of 50 cases, which we have followed up and which were investigated clinically and radiologically by myelography and eventually submitted to operation, the incidence of ruptured disks was 44%. All our cases had signs of a root lesion, but at operation we encountered many conditions other than ruptured disks. The purpose of this article is to report three cases of sciatic "neuritis" in which the lesion was found at operation and was clinically indistinguishable from a ruptured disk before operation.

We have on two occasions found a swollen oedematous nerve root, and once seen adhesions around the root in the spinal canal. In none of these cases was there any evidence of a ruptured or "concealed" disk on careful exploration of the intervertebral space, although this had been the pre-operative diagnosis; neither was there any evidence of spinal arthritis in the apophysial joints. For obvious reasons we cannot submit any histological evidence of "neuritis," but there was ample visual evidence of oedema of the nerve roots in two of the cases, and in the third the adhesions around the root were easily seen and freed. It would of course be possible to remove a piece of posterior nerve root for histological examination, but we have not thought it advisable to subject our patients to this procedure.

Case I

A miner aged 34. First seen Nov. 14, 1944, complaining of low lumbar backache, which had been present intermittently for twelve months. Says he "twisted his back" five months previously. He had occasional numbness and tingling in the two outer left toes, but definite posterior crural pain did not appear until after a period of physiotherapy. Lumbar pain was increased by sharp movements. Lasègue's sign present in left leg. Left ankle-jerk diminished. Slight objective sensory loss on outer border of left foot when leg was raised. No muscular wasting. No improvement after physiotherapy. Straight skiagrams of lumbar spine showed slight osteoarthritic lipping of adjacent anterior borders of 3rd and 4th lumbar vertebral bodies, but no thinning of the disk spaces or arthritis of the apophysial joints. Myelography after the injection of 5 c.cm. of "fluid" neohydriol showed a defect of filling of "axillary pouch" of left first sacral nerve root opposite disk between L 5 and S 1. C.S.F.: No cells; protein, 55 mg. per 100 c.cm.; W.R. negative.

Operation.—Jan. 22, 1945. Interlaminar approach on left side between L 5 and S 1. First sacral nerve root found to be thickened to about three times normal size. This was at first thought to be due to a neurofibroma of the root, but on incision of the dural sheath no tumour was found; the root was swollen and oedematous. Further decompression was made by excision of the ligamentum flavum and parts of the laminae adjacent to the opening. The intervertebral disk was explored. No extrusion could be seen, and no softening of the disk was found after incising the posterior longitudinal ligament and inserting a sharp spoon. Most of the iodized oil was removed with a syringe before closure of the wound. The patient had intense sciatic pain after the operation, which subsided gradually in about ten days, but since that time he has had no pain and has returned to full work as a miner. Lasègue's sign and the slight sensory loss had disappeared before his discharge from hospital on Feb. 12.

Case II

A male school-teacher aged 35. First seen March 20, 1945. A year ago had pain in left buttock, and left leg felt "stiff" in mornings. Occasionally had a shooting pain down back of left leg. Pain lasted throughout the summer, but later improved after physiotherapy. About a month before he was seen the pain recurred after a period of complete freedom, but much more severely. He had to be carried into hospital. Pain down back of left leg was increased by coughing and sudden movement. He says that before the onset of the pain a year ago he lifted a heavy sack and felt some strain in his lower back. On examination Lasègue's sign at 30° on left side. Pain also produced in left leg by raising right leg to 60°; left ankle-jerk diminished; scoliosis to left; slight hypo-aesthesia on outer border of left foot and shin; slight tenderness over sciatic nerve in left thigh; no muscular wasting. C.S.F.: 4 lymphocytes per c.mm.; protein, 30 mg. per 100 c.cm.; W.R. negative. Myelography by Dr. Stanley Nowell showed a notched filling defect on left side opposite disk between L 5 and S 1. There was no evidence of thinning of the disk or arthritis of the apophysial joints.

Operation.—March 28. Left interlaminar approach. No disk extrusion found and no softening of disk on incising posterior longitudinal ligament. Left first sacral nerve root showed definite swelling and oedema. The decompression was enlarged by slight excision of the laminae laterally.

This patient also had severe sciatic pain for a week after the operation, and some retention of urine. The pain recurred in attacks for several days and then subsided. He returned home on April 17 and later resumed work, but he is not yet entirely free from pain although not severely disabled. The iodized oil was not removed at operation, and a further film taken before his discharge from hospital showed that the notched filling defect remained in the same position as before.

Case III

A housewife aged 44. First seen July 20, 1944. Had had recurrent left sciatic pain for four years. Pain increased by coughing. Lasègue's sign present and left ankle-jerk diminished. No sensory loss or muscular wasting. C.S.F.: No cells; protein, 40 mg. per 100 c.cm.; W.R. negative. Myelography of the lumbar region showed a slight asymmetry of filling of the first sacral "axillary pouches," with less filling on the left side. No bony abnormality was seen and there was no narrowing of the disk spaces.

Operation.—Sept. 22. Laminectomy of L 4 and L 5. No evidence of disk protrusion on careful exploration of both disk spaces. No softening of disks found. Fine adhesions clearly seen on left first sacral root within the spinal canal. These were freed and the root mobilized. The patient made a rather slow recovery from her pain over three weeks and has remained free from pain since.

Comment

In the first case the swelling of the root was so gross that we were satisfied that it must have been due to a local tumour or very severe oedema. As there was no evidence of any disk protrusion or other cause of external pressure a longitudinal incision was made into the nerve root, which was found to be pale, homogeneous, and oedematous. The enlargement was more than sufficient to cause the defect seen in the myelograms. The prolonged and severe pain after operation is quite unusual in disk cases, but might well be expected with an inflammatory lesion.

In the second case the swelling was less marked, and we might not have felt so confident of the diagnosis but for the similarity to the first, especially in the post-operative course. In this case the iodized oil was left in the theca and, as would be expected, the filling defect persisted in a post-operative skiagram in spite of the decompressive effect of the operation.

The diagnosis of "neuritis" or "radiculitis" at operation is obviously very difficult unless gross enlargement of the root is present, and as these cases have occurred recently we think we may have missed a similar but less marked condition in some of our earlier and hitherto unexplained cases of root pain in which we found no lesion at operation.

It is impossible at this stage to arrive at any definite conclusion as to the cause of the oedema of the nerve roots which we have observed. We could find no evidence to suggest that it was due to the spread of inflammation from arthritis of the intervertebral joints. The mechanical explanation afforded by Dandy's conception of the "concealed" disk causing intermittent compression of the nerve root could perhaps be invoked to explain the oedema and even adhesions in these cases, but, as we have said, we could find no evidence of any abnormality of the disk, and we have not yet encountered any cases conforming to Dandy's description. Mechanical compression of a nerve root from narrowing of the intervertebral foramen or encroachment of posterior osteophytic outgrowths could conceivably cause the oedema we have observed, but one would expect radiological evidence of this to be visible, which it was not in our cases. Magnuson (1944) has discussed these aspects of the diagnostic problem.

If the lesions are inflammatory and no mechanical factor is concerned in their causation it is difficult to think of any condition which would affect isolated spinal nerve roots, apart from herpes zoster. There is some evidence that zoster can occur without a cutaneous eruption, but it is highly improbable that oedema of the affected nerve root would continue for many months even in those cases in which neuralgia persists. In this connexion we have recently seen a case of herpes zoster of the fifth lumbar nerve root after the removal of a fragment of a ruptured fourth lumbar disk. The patient was entirely free from pain on discharge from hospital, but returned a week later with a severe recurrence of his sciatic pain. It was at first thought that a further rupture of the disk had occurred, but within two days a herpetic eruption developed in the fifth lumbar area on the right leg. The severe pain lasted for about a week, but then subsided gradually and has not recurred.

We must leave the problem for further elucidation by observation of the "pathology of the living," as it is improbable that morbid anatomical studies will be available to provide the answer. At present we cannot differentiate these cases of "neuritis" from those with a ruptured disk before operation. We must for the moment be content with having seen a lesion which Symonds considers "has not yet been granted to human eyes."

FOOD CONSUMPTION OF WORKING-CLASS AND LOWER-MIDDLE-CLASS FAMILIES IN BRUSSELS DURING JANUARY, 1945

BY

P. A. BASTENIE, M.D., Agrégé, Univ. Brussels

Wing Cmdr. T. F. MACRAE, O.B.E., D.Sc.

Squad. Ldr. G. A. SMART, M.D., B.Sc., M.R.C.P.

AND

Squad. Ldr. S. YUDKIN, M.B., Ph.D., M.R.C.P.

(From the St. Pierre Hospital, Brussels, and the R.A.F. Institute of Pathology and Tropical Medicine)

Great concern has been shown regarding the feeding of the peoples in the occupied countries both during the German occupation and since their liberation. There have been many conflicting reports, and little reliable information has been published concerning the feeding position even in those countries which were liberated many months ago. This article gives an account of the feeding of a number of working-class and lower-middle-class families in Brussels during Jan., 1945, some four months after their liberation. It is felt that this description might assist in forming some general opinion concerning the feeding in other localities.

The rations supplied during the period chosen for this study were much the same as had been available for the whole of the period from the liberation in Sept., 1944, to Jan., 1945. They were, in fact, not greatly different from those allowed during the latter part of the German occupation, although during the first two winters of the occupation food had been in such short supply that famine oedema and other evidence of serious malnutrition were encountered in Brussels and other large cities (Bastenie *et al.*, 1944). Thus the data give a fair indication of what the people of medium economic status in Brussels have had to eat during the past two or three years. Wealthier families, by buying on the black market, have had more to eat, and others, through poverty, have had less.

Methods and Results

The information was obtained from records specially kept by 19 clerks or workers at a factory in Brussels, who noted all the purchases of food by their families during a period of one week from Jan. 8 to 14, 1945. The subjects also indicated whether the various items were bought legally or on the black market. The men were given a light midday meal at their place of work, for which they surrendered food coupons, and this was taken into account when assessing the diet of the families. No other source of food was available. Details of the composition of each family and of the income were also obtained. The excellent co-operation given by the men and by the social workers at the factory ensured that the information was reasonably reliable.

The families chosen for this investigation were those of 10 clerks and 9 workmen employed by a gas and electric company. Only men who were willing to co-operate were selected, but there was no reason, on this account, to suspect any bias whereby their diet was not generally representative of that of their economic groups as a whole. There was little difference between the incomes of the clerks and the workmen, the extreme limits being 2,066 and 4,100, with an average of 2,850, francs per month. (176 francs=£1.) The 19 families were composed of 70 individuals of both sexes and various ages.

Total	G. per head daily	379·5	14·1	598	289	39·3	47·1	30·2	2·05	12·6	11·9	5·91	37	28·9	9·0

* Expressed as grammes per head of milk solids.
† " " " fresh eggs. Average weight of one egg taken as 55 g.

The basic analysis of the results is shown in Table I, where the daily amounts per head of the various items of food from the three different sources are shown; the percentage of each item obtained from the shops legally, from the black market, and from the works canteen is also given. The bulk of the food was obtained legally. Nevertheless 11 of the 24 francs spent daily per head on food were spent on the black market. Calculation shows that a calorie cost about 6½ times as much on the black market as when legally obtained.

Table II gives a comparison between the total food obtained by the Brussels families and that moving into consumption in the United States, Canada, and the United Kingdom in 1943 (see *Food Consumption Levels*, 1944). The Brussels diet was particularly low in meat products, dairy products, and fats, whereas cereal products and potatoes formed an unusually high proportion of the diet. With such a combination of foodstuffs it was very difficult to prepare palatable meals. It should be pointed out, however, that even in normal times large quantities of potatoes are eaten in Belgium. As would be expected, a close correlation existed between the amount of a given foodstuff bought on the black market and its deficiency on the legal market.

TABLE II.—*Comparison of Amounts of Food obtained by the Families in Brussels in Jan., 1945, with that moving into Consumption in United States, Canada, and United Kingdom in 1943*

	Grammes per Head Daily			
	Brussels	U.S.A.	Canada	U.K.
Milk and milk products, excluding butter (expressed as milk solids)	31	80	79	61
Meats, including cured and canned and edible offal (carcass weight)	39	176	166	133
Poultry, game, and fish (edible weight)*	28	34	33	23
Eggs (fresh equivalent)	5·9	51	47	28
Oils and fats (fat content)	20	55	54	48
Sugars and syrups (sugar content)	54	104	98	81
Potatoes and sweet potatoes	598	193	255	318
Pulses and nuts (weight without shell)	0·51	24	14·5	6·9
Tomatoes and citrous fruits†	0	128	76	29
Other fruits and vegetables	288	202	184	310
Grain products	289	250	268	308
Beverages‡	9	18	13	15

* Only fish was obtained by the families studied in Brussels.
† No tomatoes or citrous fruits were available in Brussels during Jan., 1945. Tomatoes, however, are available in considerable quantity during the summer months.
‡ These include tea, coffee, and cocoa in the U.K., Canada, and U.S.A.; in Brussels only artificial coffee made from malt and chicory was available.

Table III shows the amounts of the various nutrients per head daily, obtained by the families in Brussels from all sources; the total amounts are compared in Table IV with those moving into consumption in the United States, Canada, and the United Kingdom in 1943 (see *Food Consumption Levels*, 1944). In calculating the values for the Brussels families the Combined U.K./U.S.A./U.N.R.R.A. Working Party Food Tables for European Food Supplies (see *Nutrition and Relief Work*, (1945) with corrections kindly supplied by Dr. B. S. Platt, have been used. The nutritive values of the food moving into consumption in the United States, Canada, and the United Kingdom have been calculated from other food tables (see *Food Consumption Levels*, 1944). However, this difference is small and does not invalidate the comparisons.

TABLE IV.—*Comparison of the Nutritive Value of the Diet of the Families in Brussels in Jan., 1945, with that of the Population in the United States, Canada, and United Kingdom in 1943*

	Amounts per Head Daily										
	Kilo-calories	Protein	Animal Protein	Fat	Calcium	Iron	Vit. A	Vit. B_1	Riboflavin	Nicotinic Acid	Ascorbic Acid
		(g.)	(g.)	(g.)	(mg.)	(mg.)	(i.u.)	(mg.)	(mg.)	(mg.)	(mg.)
Brussels	2,100	66	19	43	572	17	6,200	1·8	1·3	13	167
U.S.	3,130	95	56	138	996	16	6,979	2·4	2·3	20	106
Canada	3,120	97	57	133	956	16	6,783	2·0	2·1	19	61
U.K.	2,827	87	40	113	1,054	16	5,000	2·1	2·1	19	127

An assessment of the nutritional adequacy of the Brussels diet can be made by "weighting" for the individuals of different age and sex comprising the 19 families. Table V gives the amount of each nutrient in the diet of the Brussels families expressed as a percentage of the amount they should have received on the basis of the National Research Council Recommended Dietary Allowances (quoted in *Food Consumption Levels*, 1944) and also on the basis of actual intake values found by Dr. R. A. McCance and Miss E. M. Widdowson

TABLE V.—*Nutritive Value of the Diet of the Families in Brussels expressed as Percentages of National Research Council Recommended Dietary Allowances and of McCance and Widdowson's "Found" Values*

	Percentage of N.R.C. Recommended Dietary Allowances	Percentage of McCance and Widdowson's "Found" Values
Kilocalories	82	87
Total protein	106	91

(private communication) for British middle-class families in the few years before the war. It is apparent that the chief deficiencies are in calorific value, animal protein, fats, calcium, and riboflavin. It is noteworthy that except for riboflavin there is no obvious deficiency of vitamins. Although the Brussels diet is not deficient in total protein the proportion derived from animal sources (29%) is unusually low: this might affect the biological value of the total protein. Moreover, some 40% of the animal protein was derived from milk, which was allocated almost entirely to children, so that the adults must have received an even smaller amount of animal protein than would appear from the tables. Similarly, since 60% of the calcium in the diet was derived from milk, the adult intake of this mineral must have been strikingly low. The deficiency of riboflavin is brought about by the shortage of dairy products, meat, and eggs, which, for example, in the United Kingdom in 1943 supplied 60% of the total riboflavin of the diet (*Food Consumption Levels*, 1944).

No attempt has been made to assess the intake of vitamin D, but the diet obviously contained little of this nutrient. However, most children received supplements of calciferol from benevolent sources.

It should be stressed that the rationing system gave high priority to young children. In fact, their allowances were more than they could possibly have eaten (Bastenie *et al.*, 1944). Thus the food position of the families with young children was usually satisfactory, whereas families without children or with children of 12 to 18, whose requirements were high but for whom no extra rations were available, had much less adequate diets.

Comment should be made on the fact that apparently about 92% of the earnings of the families studied was spent on food. Five factors accounted for this. (1) Past savings were drawn upon with monotonous regularity. (2) When they had all been spent, debts were piled up. (3) As has been pointed out by Ellis (1945), rationed foodstuffs were bought and then sold on the black market to provide money for the purchase of other foods; great nutritional bargains were sometimes made in this way. (4) The coupons for rationed items which were not available were sold at a high price to people who lived in districts where these foodstuffs could be obtained. (5) Many took an active, though small, part in black-market activities; for example, they might go at the week-end to the country, purchase food from a farmer, and bring it back to town, there to sell the greater part at black-market prices.

Summary and Conclusions

By means of household budgets a dietary survey has been made on the families of 19 Brussels workers during Jan., 1945.

The amounts of meat products, dairy products, and fats available to the families in Brussels were low. This is strikingly apparent when comparison is made with the amounts of these foodstuffs available in the United States, Canada, and the United Kingdom during the war. Cereal products and potatoes formed an unusually high proportion of the diet in Brussels.

The nutritive value of the diet in Brussels has been compared with that of the diet in the United States, Canada, and the United Kingdom during 1943, with that of the diet in the United Kingdom before the war as found by McCance and Widdowson, and with the National Research Council Recommended Dietary Allowances. The comparison shows that the diet in Brussels was deficient in calorific value, calcium, riboflavin, animal protein, and fats. There was no obvious deficiency in other nutrients, but vitamin D may also have been inadequate in the diet of adults.

We wish to thank Air Marshal Sir H. E. Whittingham for enabling us to carry out this work and for his encouragement. We would also thank the Director of the Electro-Gaz works, Brussels, and the subjects and their families for their co-operation. We also record our gratitude to the social workers at the Electro-Gaz works, who gave us much assistance in obtaining the data.

This work was undertaken at the request of the Subcommittee on Post-War Nutritional Research of the Accessory Food Factors Committee of the Medical Research Council and the Lister Institute of Preventive Medicine.

A CASE OF LOCAL TETANUS

BY

FRANK A. ELLIOTT, M.B., M.R.C.P.

Major, R.A.M.C.; Command Neurologist

The term "local tetanus" is used to denote those cases of infection by *Cl. tetani* in which muscular spasms and contractures are limited to one region of the body throughout the course of the disease. It is often extended to cases in which the tetanic manifestations are predominantly rather than exclusively local and to those with a prolonged local phase before a terminal generalization. Though referred to by earlier writers, the modern study of local tetanus started with a paper by Courtellemont in 1915. The diagnosis was made with increasing frequency, and by 1918 accounted for 19.2% of all cases of tetanus among casualties treated in the United Kingdom (*Official History of the War*, 1922). The most frequent form was the monoplegic, affecting an arm or a leg, but paraplegic, cephalic, and (rarely) abdomino-thoracic types were recorded. Splanchnic tetanus, so called because it follows a visceral infection, is "local" only inasmuch as the patient dies of asphyxia before generalization can occur.

The features of local tetanus were widely appreciated by the end of the last war, but all forms of the disease have become less common, and there is a risk that the rarer types may escape recognition for a longer period than is desirable in the interests of the patient. It is therefore thought justifiable to record a case, recently studied by Major A. G. Emslie, R.A.M.C., and me. The patient was seen four months after wounding and two months after the onset of what was taken to be a spastic paralysis of the right leg.

History of Case

The patient, a man aged 22, had received no tetanus toxoid or other prophylactic measure before he was wounded on Aug. 21, 1944. The injuries occurred in the chest, left shoulder, abdomen, and anterior aspect of the right thigh in its upper third. He was given 1,500 units of A.T.S within 12 hours. Débridement of all wounds was carried out within 24 hours, and he was then given 9,000 units of anti-gas-gangrene serum on account of the dirty condition of the wound in the thigh. He made a good recovery, and was discharged from hospital on Oct. 11, 51 days after injury. He remained fit for a further three weeks, after which he noticed a dull pain with stiffness in the region of the right hip. This gradually became worse, and he reported sick on Dec. 22. Until then he had been up and about, and throughout his illness he preferred to stay out of bed, as walking relieved the ache in his thigh. Examination on Dec. 29 revealed a cheerful healthy-looking man. Temperature and pulse were normal. All wounds were healed. The cranial nerves were normal. There was no trismus. Power, tone, sensation, and reflexes were normal in the arms and left leg. The right leg was held in an attitude of semiflexion at the hip and full extension at the knee. There was a slight increase of the lumbar lordosis. The lumbar muscles on the right were somewhat tense as compared with those on the left. The tensor fasciae latae, quadriceps, and adductors on the right were hard, tender, and could not be made to relax, but the hamstrings and muscles below the knee were normal. The right knee-jerk could not be elicited owing to the rigidity of the knee. The ankle-jerk was somewhat accentuated. The plantar responses were vigorously flexor. Sensation was normal throughout. The rigidity above the knee was such that the hip-joint seemed ankylosed. No spasms were seen. Radiographs showed a small metal foreign body lying to the inner side of the femur in its upper third. Blood count and sedimentation rate were normal.

A tentative diagnosis of local tetanus was made; this was supported by the observation that the contracture persisted in sleep and under pentothal anaesthesia—a fact which excluded the possibility of a hysterical condition. The consultant physician, Brig. Stevenson, considered the clinical indications definite enough to justify immediate treatment. The patient was given 40,000 units of A.T.S. intramuscularly daily for two days, followed by 100,000 units intravenously in saline on the third day. On the fourth day the wound in the thigh was explored and the foreign body removed. He received 80,000 units on the day of operation, followed by 40,000 units daily for three days. He thus had a total of 380,000 units of serum in 7 days. Despite the operative intervention no trismus or other evidence of generalization occurred.

Cultures taken from the foreign body gave a growth of *Cl. tetani* and *Cl. welchii*—an association often met with in tetanus. In order to control any remaining organisms left in the wound he was given a four-day course of penicillin, amounting in all to 400,000 units, by intramuscular injection at three-hourly intervals. The contractures slowly declined, and tone was normal in the affected muscles 7 weeks after operation. He has remained well since then.

Comment

The long incubation period of two months is not unusual in local tetanus, though in many cases—notably in Bruce's 1918 series (*Official History of the War*, 1922)—it has obviously been an artifact due to the giving of repeated doses of antiserum at weekly intervals after wounding.

As a rule local tetanus arises in subjects who have had antiserum, but this is not always the case. Claude and Lhermitte (1915) have described a case in which no antiserum was given, and have further drawn attention to the existence of an attenuated form of generalized tetanus in which spasms do not occur, symptoms being confined to painful contractures which interfere but little with the patient's activities. Clearly the varying balance between the patient's passive immunity and the strength of the infection will provide a wide choice of clinical pictures.

This case illustrates the manner in which the toxin, ascending along peripheral nerves, involves a sharply demarcated zone of grey matter. The muscles involved were those supplied by the upper lumbar segments on one side only. If contracture was present in muscles above and below this level it was not clinically apparent.

As regards treatment, the large quantities of antiserum given were designed to prevent the generalization which has sometimes occurred after surgical intervention in this type of case. Penicillin was used to control any organism still left; but the happy outcome cannot be attributed to that drug, since many cases of local tetanus have been known to recover after removal of a foreign body and the use of serum alone. Nevertheless, it would seem to be a useful insurance in such cases.

My thanks are due to Lieut.-Col. P. A. Stewart, R.A.M.C., for permission to publish this case.

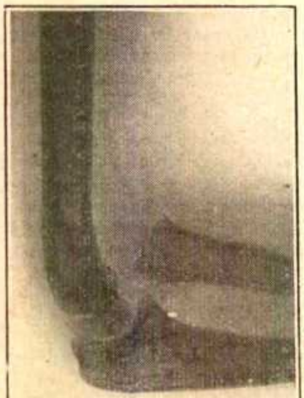
Medical Memoranda

Congenital Recurrent Dislocation of Head of Radius

One feels that this case is worthy of report not only on account of the rarity of the condition but also because of the unique features presented in this particular instance. Twenty-two cases of congenital dislocation of the head of the radius, unaccompanied by other lesions, have been recorded, but in only one (Mauck and Butterworth, 1938) was the dislocation recurrent and completely reducible, and in that case the condition was bilateral, with reduction occurring in full extension.



CASE REPORT

On Jan. 16, 1945, a girl aged 9 was brought to the orthopaedic out-patient clinic of Durham County Hospital with the complaint that exactly one week previously, while attempting to loosen a button on the left shoulder with her right hand, she suddenly felt pain in the right elbow, and noticed that a "lump" appeared in front of the elbow, which disappeared on manipulation. The pain was momentary, and not severe. No history of any previous injury to the elbow was offered. Her birth was by Caesarean section at seven months' gestation, and the birth weight was only 4½ lb.

Examination showed that the patient was a well-developed, intelligent child. The left elbow was normal. Inspection of the right elbow revealed no swelling or bruising. Flexion, pronation, and supination were full. Very slight limitation of extension was present, and the tendon of the biceps with its aponeurosis was unduly prominent in the last few degrees of extension. When the patient extended the elbow past 90°, in supination, the head of the radius dislocated forwards, without pain. It could be reduced with ease by simple thumb pressure. Dislocation was not possible in pronation or in flexion beyond the right-angle.

Radiographs showed that the head of the radius was shallow and poorly formed. There were no additional zones of ossification about the elbow. The ulna had no tendency to anterior curve of the upper aspect of its anterior and posterior borders, as described by McFarland (1936). The radius was not longer than normal.

COMMENT

The absence of any history of trauma and the x-ray appearance of the head of the radius strongly suggested that the condition was of congenital origin. The complete absence of disability rendered any immediate radical treatment, such as orbicular ligament reconstruction, unjustifiable. Excision of the head of the radius was particularly contraindicated by the age of the child.

It was explained to the mother, however, that as the radius grew, dislocation for appreciable periods would permit of undue lengthening of the bone, with the probable result that dislocation would become permanent, and limitation of movement ensue. In that event excision of the head of the radius would be considered.

My thanks are due to Mr. A. H. G. Munro, hon. orthopaedic surgeon Durham County Hospital, for permission to publish this case, and for his help and advice.

ELLIS BINDMAN, M.B., Ch.B.,
House-surgeon.
Durham County Hospital.

Operation for Recurrent Subluxation of the Temporo-mandibular Joint

In the *Journal* of Sept. 23, 1944 (p. 423), there appeared a letter on the subject of "clicking mandibles." This, and the reply given, prompt me to send the following case record.

An airman in the R.A.F. Regiment was first seen in Feb., 1944. He complained that when he opened his mouth there was a loud click on the right side. When eating, the click would often be associated with a sharp pain in the region of the right temporomandibular joint, severe enough to cause him frequently to abandon his meals. He gave a history of having been an amateur boxer, but he had never had his jaw dislocated or fractured.

In Jan., 1943, he had undergone a dental clearance, and had been fitted with dentures. Six months later he noticed the clicking of the jaw. On examination the click was obviously associated with a partial subluxation of the right temporo-mandibular joint. When he closed his mouth the subluxation was spontaneously reduced. A radiograph of the joint failed to show evidence of osteo-arthritis. He maintained that his condition caused him much disability, and he agreed to submit to operation even after the uncertainty of a cure and the relative certainty of a frontal paralysis had been explained to him.

At operation the right temporo-mandibular capsule was exposed through a curved incision. The capsule was found to be lax. A vertical incision was made in the capsule, and the cut edges were then overlapped and sutured so as to tighten it in an antero-posterior plane. Two sutures were also inserted to draw a very small "pleat" of capsule up to the root of the zygomatic process, and by this means tighten it in a vertical plane. The mandible was then "immobilized" in a jaw splint for seven days. Right frontal paralysis followed the operation. On removal of the jaw splint the patient was able to open his mouth, insert his dentures and eat, without his jaw clicking, and without his old pain. He was seen again in June, 1944, when the right frontal paralysis had completely recovered. According to the patient's statement, recovery had occurred suddenly ten weeks after the operation. He could open his mouth widely without any recurrence of his symptoms, although there was still slight deviation of the point of the jaw to the left. The scar of the operation is inconspicuous.

He was last seen on March 3, 1945, and was then still symptom-free.

For permission to publish these case notes I am indebted to Sir Harold Whittingham, Director-General of Medical Services, Royal Air Force, and to Wing Cmdr. H. F. Harvey, officer commanding our Mobile Field Hospital. I wish to thank Air Cdre. Stanford Cade, Consultant in Surgery to the Royal Air Force, for much help and encouragement.

H. N. G. HUDSON, M.B., F.R.C.S.,
Squadron Leader, R.A.F.V.R.

Reviews

PREVENTIVE MEDICINE

Lectures on Preventive Medicine. By Harvey Sutton, M.D., D.P.H., F.R.A.C.P. (Pp. 658; illustrated. 27s. 6d.) Sydney: Consolidated Press Ltd., 168, Castlereagh Street. 1944.

After six years of war it is no easy matter to give a fresh account of preventive medicine for the student. We have lived so much on improvisation that there have been no real standards since 1938. Col. Harvey Sutton has given us a new start by publishing a series of lectures, based to a considerable extent on recent Australian figures. This work does not pretend to be a textbook, but there is a wide and interesting range of subjects and each one is fully treated. He is evidently specially interested in genetics and the problems of hereditary transmission of mental defect, as he devotes a racy chapter to the subject. The section dealing with maternal mortality is illustrated by recent Australian figures. Some of the conclusions indicate that the age of the mother is a more important factor in mortality than the order of birth; that the first birth is the safest, the mortality rising sharply after the sixth child. In other words, " the young primipara is by far the safest in child-bearing and the multipara over 35 most deserves attention." Sutton estimates that in 1940–1 there were 20,000 deliberate abortions (66 per 1,000) and 15,000 accidental (50 per 1,000). The total natal and neonatal losses were 56 per 1,000—less than half the wastage from abortion and miscarriage. Australia compares very favourably with the other nations in its infant mortality rate, with figures ranging from South Australia (33) to New South Wales (42). The best annual figures in recent years have been Adelaide (27.36) and Perth (27.96).

About half of the lectures are devoted to communicable diseases. Col. Sutton has been at great pains to bring his material up to date, and the section on vectors is well illustrated. The historical notes are often amusing, but the text is in parts little more than a catalogue. In dealing with the epidemiology of infantile paralysis his bewilderment and his honesty are both in evidence. After giving a list of the usual precautions against infection he turns in a kind of aposiopesis to exclaim: " It is curious how often children who have been most carefully kept away from contact with others seem, when the epidemic comes, the very ones to go down with the disease. The history of previous freedom from any infectious disease is more frequent in cases than the community of children." Yet he is content to talk about carriers, and does not draw the inference which is implicit in his observation.

This is a vigorous book, well worth reading, and not seriously marred by wisecracks and quotations from political authors.

PLASTER-OF-PARIS IN SURGERY

Plaster of Paris Technic. By Edwin O. Geckeler, M.D. (Pp. 220; illustrated. $3.00, or 16s. 6d.) Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox.

Is the skilful use of plaster-of-Paris in surgery an " art " or a " craft "? Dr. C. L. Scudder, in his foreword to this very valuable book, regards it as an art. This cannot be so, for the art of medicine must be bigger than technical procedures which are only a part of it. The art of any branch of medicine is to determine the nature of disease and apply its cure. There is craftsmanship in painting, sculpture, music, and poetry, but the techniques employed are not art. This is important, for to be an orthopaedist one must be more than a skilful user of plaster-of-Paris. In Britain several publishers of art books produce for the beginner works on " How to do it." Valuable as they are, the writers usually recognize that ultimately one cannot learn art, even artistic craftsmanship, from books. One must study the work of the masters and be taught practically by a master. So it is with plaster technique in surgery. Therefore it must be appreciated that the book under review is merely a guide, though a good one, for the beginner or practitioner who is forced to undertake work for which he has no practical training. The need for the latter should be stressed.

There are minor points to criticize—e.g., the uncertainty revealed as to whether the toes in leg casts should have plaster support beneath them and whether, generally speaking, the foot should be held at a right-angle. Too often in the illustrations the negative is portrayed while the positive view is stated in the text. Whilst improvisation, where necessary, should be described, the method here portrayed for fractures of the spine is bad and should not be fathered upon Watson-Jones. As this book can only be meant for beginners, unsafe measures should be avoided. At any rate in this country we would regard as such the use of transfixion pins for fractures of the femur and tibia. More emphasis should be placed upon the difficulties of swelling occurring within plaster splints—certainly one of the objectionable features the prevention and treatment of which should have much more space devoted to them. The medico-legal aspects of this complication ought to be touched upon, together with a description of the form of printed instructions which in this country is almost everywhere distributed to subjects who are being treated with plaster-of-Paris as out-patients.

THE PATIENT IN HIS SETTING

Patients Have Families. By Henry B. Richardson, M.D., F.A.C.P. (Pp. 408. $3.00, or 16s. 6d.) New York: The Commonwealth Fund; London: Oxford University Press. 1945.

In the study of the patient the most conspicuous objective factor is the symptom, which is of course most important to the patient himself. To the doctor, we hope, the symptom is only part of the disease, and too often the study of the situation stops there; but the disease is part of the individual, the individual of the family, and the family of the social group. The doctor cannot fully appreciate the whole situation unless he studies all these factors. It is to be hoped that the new chairs of social medicine will soon familiarize the profession and the public with this truth.

Here is a book from America which describes work parallel with that of the Peckham Centre, and shows the enormous influence which interactions within the family group have in determining the health or ill-health of the various individual members. The effects of infection are obvious, and so perhaps are those of dietary and general habits of exercise and the like; but too little thought is usually given to the effects of suggestion, imitation, and identification in the production of psychosomatic manifestations. Other factors to be kept in mind are the general equilibrium of the family, and personal dominance (even of dead members) in the genesis of anxieties and other psychoneurotic manifestations. Such considerations are, or should be, familiar to the family doctor—the general practitioner in this country; hence his importance—but they are not to the vast majority of consultants and specialists, and Dr. Richardson is rightly concerned with this in America, where few family doctors exist. Is family doctoring to be a new specialism or an integrated team? Be this as it may, integration of team work is necessary, bringing in hospital physician, psychiatrist, social worker, and health visitor, and the author indicates how this may be brought about. He discusses the family as a subject of research, and adds in appendixes various techniques for carrying out such investigations.

This is an important book which deserves to be studied by all concerned with the new health services, for if we are to secure health and not merely fight disease we must get beyond our elaborate instruments, however useful, and our laboratories, however well equipped, to the setting and surroundings of our patient as a member of a family unit.

PSYCHOLOGICAL DEVELOPMENT OF THE CHILD

L'Évolution psychologique de l'Enfant. By Henri Wallon. Collection Armand Colin No. 232. (Pp. 223. No price given.) Paris: Librairie Armand Colin. 1941.

The way in which the mind of the child develops is of importance both for education and for psychology. Much study has been devoted to the subject in recent years and many different approaches have been used, all contributing to the sum of knowledge which is reviewed in this book. In the first part there is a comparison of the child with the adult. It is pointed out that the child's mind is quite different from that of the grown-up and so requires special methods for its study and an appreciation of the way in which it develops. The second part deals with the activities of the child and how they develop with special reference to play. The third part studies more general applications, such as the emotional life, motor activities, the growth of knowledge, and the formation of the personality. All this is summed up in a brief sketch of the successive ages of childhood.

This is an interesting survey of child psychology which may be useful as an introduction to what is now an extensive literature.

Notes on Books

In 1941 we favourably reviewed the fourth edition of a *Textbook of Surgical Pathology*, by Prof. C. F. W. ILLINGWORTH and Mr. B. M. DICK. The fifth edition (J. and A. Churchill; 42s.), which has now appeared, incorporates some changes and additions to bring the matter up to date. In particular the articles on surgical shock and burns are new, and short descriptions are given of the crush syndrome, sarcoidosis, argentaffine tumours, and other conditions. The quality of the new matter is up to the general standard of the book. We see no reason to change the good impression which we previously expressed.

A Study of Endometriosis, Endosalpingiosis, Endocervicosis, and Peritoneo-ovarian Sclerosis, by Dr. JAMES ROBERT GOODALL, formerly professor of clinical gynaecology and obstetrics at McGill University, was warmly welcomed in these columns on Nov. 18, 1944. The original edition was exhausted in a few months, and J. B. Lippincott Company have now published a second (35s.). The only change of consequence is the addition of a new chapter on the urinary complications arising out of pelvic endometriosis, which vary from slight derangements of function to complete destruction of the organs of the tract.

The Wellcome Historical Medical Museum has arranged to publish shortly, in conjunction with the Oxford University Press, a book on *The Development of Inhalation Anaesthesia* from 1846 to 1900, by Dr. BARBARA M. DUNCUM, of the Nuffield Department of Anaesthetics, University of Oxford, and formerly on the staff of the Wellcome Historical Medical Museum. This will be the first of the Museum's post-war series of research studies in the history of medicine. It deals exhaustively with the history of inhalation anaesthesia in Britain, the United States of America, and on the European continent, from the scientific and clinical points of view. Features of the work are its investigation of the changes of opinion in regard to the physiological action of anaesthetics, the evolution and practical application of inhalers and other apparatus, and the introduction and adoption of anaesthetic drugs, during the period under review.

Dr. Rudolf A. Stern's *Trauma in Internal Diseases* was reviewed in the *Journal* of Aug. 18 (p. 220). We are informed by William Heinemann (Medical Books) Ltd. that an English issue of this book will appear under their imprint towards the end of the year at the price of 30s.

Preparations and Appliances

A CHEAP HOME-MADE SPECTROSCOPE

Dr. B. J. FREEDMAN sends the following description of an apparatus of low cost which can be readily set up in the laboratory, suitable for examining the absorption spectra of blood and other fluids:

Rationale

The spectrum is produced by a diffraction grating replica. This consists of a sheet of collodion 1.5×1 cm., which is a surface cast of a small sheet of glass, the original grating, on which about 14,400 parallel grooves to the inch are accurately and evenly ruled with a diamond. The replica, as sold by Adam Hilger Ltd. (Fig. 1), is surrounded by a black paper mask, and mounted between two sheets of glass 5×4 cm. for convenience in handling. If a ray of white light strikes a grating, most of the light passes straight through unaltered. A proportion on passing through is diffracted by the parallel lines, and deflected into two beams diverging on either side of the unaltered beam, the red rays being deflected more than the violet. If, therefore, a grating is held close up to one eye and a source of light is inspected through it a spectrum will be visible on either side of the light source. The grating produces a spectrum equally dispersed at all wave-lengths, unlike a prism or system of prisms, which compresses the spectrum towards the red end. The grating also causes greater dispersion, thus yielding greater resolution of wave-bands and hence wider separation of absorption bands. Any slight shift in position of absorption bands, as occurs on the conversion of oxyhaemoglobin to carboxyhaemoglobin, becomes correspondingly more apparent.

The slit is represented by the linear filament of a double-capped tubular lamp, of the type commonly used in shop windows and radiant-heat cradles. It is supported in the usual sockets, which are mounted one above the other on a board painted a dull black or covered with black cloth (Fig. 2). Alternatively the reflector in which this type of lamp is normally housed may be blackened and used instead. If the grating is now held up to one eye with the short sides of the mount vertical, and the incandescent filament is inspected through it, the spectrum will be seen on either side of the filament. If a sheet of coloured glass or an optical cell containing a clear coloured fluid is interposed between the grating and the lamp, absorption bands will appear in the spectrum (in the same manner as when using a prismatic spectroscope), corresponding to the wave-lengths that have been absorbed. A test-tube of about 1 in. diameter is in many ways better than an optical cell, and is of course incomparably cheaper. Such a test-tube when filled with fluid is a cylindrical convex lens, and, held parallel with the lamp filament (i.e., vertically) and a yard or two from it, causes a real image of the latter to be formed about 1 cm. outside the test-tube diametrically opposite the lamp. With a test-tube held at arm's length in the left hand, in a direct line between the lamp (which should be about 2 yards away) and the observer's eye, this real image will be seen as a bright line apparently running down the centre of the test-tube. This bright line will function as the spectroscopic slit, and will assume the tint of any coloured fluid placed in the test-tube. If now the grating is held close up to the eye with the right hand the spectrum with absorption bands will be clearly seen. A test-tube of smaller diameter is not recommended, as the image of the filament thereby becomes too narrow and lacking in brightness. As is the case with other types of spectroscope, the depth of colour must be optional; if too deep, neighbouring bands broaden and fuse, and the characteristic absorption spectrum of the fluid becomes unrecognizable. Using a test-tube of 1 in. diameter, three drops of blood in 3 in. of water gives a suitable concentration, in the absence of anaemia. Accuracy here is not necessary, and errors can be quickly corrected by adding a little water, or another drop of blood, accordingly.

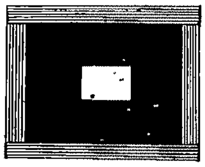

FIG. 1

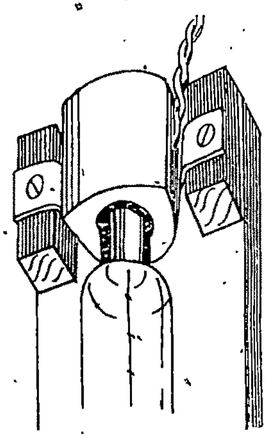

FIG. 2

FIG. 1.—Grating—replica in centre; black paper mask surrounding; edges bound with passe-partout. (One-quarter actual size.)

FIG. 2.—Showing brass strip holding socket to wood blocks. (One-quarter actual size.)

It is advisable to darken the room somewhat, or at least to see that no light objects are near the lamp, as these may obtrude themselves on the spectrum. The rationale has been gone into in some detail because readers may be unfamiliar with the diffraction grating.

Apparatus

1. Double-capped tubular lamp, obtainable from any electrician.
2. Pair of sockets for above, fixed to a black board as illustrated or in a blackened reflector. Sockets mounted on a metal rod and spaced the correct distance are obtainable from Linolite, Ltd. A few feet of twin flex and adaptor connected to the sockets.
3. Diffraction grating replica, obtainable from Messrs. Adam Hilger, 98, St. Pancras Way, London, N.W.1; price 4s. 3d.; catalogue No. K12.
4. Test-tube about 1 in. in diameter.

The total cost is a little over ten shillings.

Technique

1. The solution in suitable concentration is placed in a test-tube about 1 in. in diameter. If blood is being examined, about one drop per inch of water is the correct dilution. Cloudy fluids should first be cleared by centrifugation or filtration. The outer surface of the test-tube should be dry, because drops or smears of fluid impair its function as a lens.
2. Light the tubular lamp, which should be placed in a vertical position.
3. It is advisable, though not essential, to darken the room slightly.
4. Standing at a distance of about 2 yards from the lighted lamp, hold the grating, short side vertically, close up to one eye and observe the spectrum on one side of the lamp.
5. Holding the test-tube at arm's length in the other hand, parallel with the lamp filament (i.e., vertically) and on a level with it, move it across until it is interposed between the grating and the lamp.
6. The somewhat obtrusive direct (undiffracted) rays can be screened off by turning the head a little to one side, thereby interposing the black paper mask which surrounds the grating.

The procedure is simple, though this description may seem complicated to those unfamiliar with the diffraction grating. The advantages claimed for this apparatus over the usual pocket prismatic spectroscope are: (1) low cost; it is to be recommended where expense is a factor; (2) greater dispersion, yielding increased resolution of neighbouring absorption bands.

WORK AT HIGH TEMPERATURES

To those concerned with the welfare of men and women who work at high temperatures, whether they be industrial workers or Service personnel, it is of no small importance that the limiting conditions under which work can be done should be known. There arises straight away the question how environmental warmth should be measured. Comfort and the body's reactions to its thermal environment depend on four distinct factors: the temperature, humidity, and rate of movement of the air, and the radiation from the surroundings. A perfect index of warmth would need to give due weight to each of these factors. It often happens in buildings, and generally in mines, that the temperature of the radiating surfaces is substantially that of the air, so that the reading of the dry-bulb thermometer indicates the radiation from the surroundings as well as the temperature of the air. Then, at comfortable temperatures, a tolerably good indication of warmth is given by the reading of the ordinary thermometer. In hotter environments, however, the humidity of the air is of increasing significance, for in the limiting condition the whole, or nearly the whole, of the heat produced by the body must be dissipated by the evaporation of sweat.

One index of warmth which is influenced by both the temperature of the air and its moisture content is the wet-bulb temperature. Forty years ago J. S. Haldane[1] concluded that the wet-bulb temperature is the limiting factor of the environment which determines the ability of man to retain his heat balance, and that a higher wet-bulb temperature can be tolerated if the air velocity is increased. Haldane gave the limiting wet-bulb temperature for resting men as 88° F. in still air and 93° F. when the air velocity was 170 feet per minute. Almost similar results were obtained for saturated air by McConnell, Houghten, and Yagloglou[2] twenty years later. Houghten and Yagloglou[3] had already developed the scale of effective temperature which is now in general use in the United States: this takes into account air temperature, humidity, and air velocity, but it gives greater weight to air temperature than is allowed for in the wet-bulb temperature. Pulse rate and rectal temperature were found to correspond closely with effective temperature. Haldane,[4] however, still maintained that wet-bulb temperature was the only thing that mattered.

During the war acclimatization to high temperatures has been extensively studied, and other investigations have been made of the upper limits of environmental heat which can be tolerated by acclimatized men. In his Croonian lectures, published in this *Journal* last month, Macdonald Critchley gave a most interesting account of the climatic problems of naval warfare. Eichna and his colleagues[5] studied acclimatized men who were nude except for shoes and socks and, sometimes, cotton shorts. The men spent eight to nine hours a day in the hot environment, five hours a day being spent in continuous marching. Dry-bulb temperatures ranged from 93° to 121° F., and wet-bulb temperatures from 90° to 96° F. The limiting factor was clearly the wet-bulb temperature, while the dry-bulb temperature exerted but a minor influence. At these high temperatures even a slight increase in the wet-bulb temperature is of importance. Only 4° to 5° F. of wet-bulb temperature separates environments in which work is comparatively easy from those in which it is impossible. Men work easily and efficiently at wet-bulb temperatures below 91° F. At wet-bulb temperatures of 91° to 94° F. prolonged and moderately hard work can be done, but it is done inefficiently and with difficulty, at the cost of loss of vigour and undesirable physiological changes, and with some risk of heat casualties. Above 94° F. wet-bulb temperature most men soon exhibit disturbing changes and can tolerate only about one hour of sustained, moderately hard work. Continuance of work for a longer time is at the cost of strong physiological disturbances, while the work is most inefficiently done. The limiting wet-bulb temperatures are only about 2° F. higher with dry-bulb temperatures below 100° F. than when the air temperature is 120° F. Very similar results have also been reported by Robinson and his team.[6] For men walking in shorts the upper limits at which thermal equilibrium could be maintained, with an air velocity of 180 feet per minute, were an air temperature of 93° F. and 91% relative humidity, or 122° F. and 21% humidity. These conditions respectively represent wet-bulb temperatures of 91° and 84° F., and the corresponding effective temperatures are approximately 89° and 92° F. Here again the effective temperature scale makes too much allowance for air temperature. From this work it seems clear that at the upper tolerable limit of warmth the wet-bulb temperature is the most significant factor, and that the effective temperature scale needs some revision. Another shortcoming of the scale is that it makes no specific allowance for radiant heat, so that when the mean radiant temperature differs much from the air temperature an erroneous impression of the warmth of the environment is given. This source of error is readily apparent when normal room conditions are considered; and that it is important also at high temperatures is clear from the observations of Houghten and his colleagues.[7]

In spite of its faults the effective temperature scale is a valuable aid to engineers who are mainly concerned with the central-heating of buildings, but a scale of warmth is required which will allow adequately for each of the four thermal factors of the environment. For a restricted range covering the comfort zone such a scale of equivalent warmth was put forward by Bedford,[8] but there is a pressing need for scales which will cover the whole range of conditions from cold to great heat, and which will apply to persons who are resting or engaging in work of varying degrees of severity.

THE DECAYING VILLAGE

Life in a small village in England, whatever its outward attractions, means almost inevitably for many of the inhabitants a deprivation of some of the comforts and conveniences which a townsman takes for granted. In some villages the housing standard is deplorable. Below the thatched roof of the picturesque cottage and behind its too-small casements may be living conditions as bad as those to be found in the back streets and hidden courts of towns. Public services such as piped water, efficient sewerage, gas, and electricity are often not available, and social and recreational activities are difficult to maintain. This is amply illustrated in a survey undertaken by the Agricultural Economics Research Institute, Oxford,[1] of a little stretch of country in the South Midlands, 24 square miles in extent, comprising three large villages and twelve small ones, with a population of about 6,000 (having declined by 2,000 during half a century). The investigators—fifteen people, nearly all of them with university degrees—have explored the life of the rural labourer from his pre-natal clinic to his old-age pension. Such matters as the domestic budget, the methods of farming, the teaching in the (mostly old and ugly) schools, the attendance at church, the place of the "pub" in the life of the community, the health services and charities, the government of the village (very undemocratic as a rule) are all dissected expertly and sympathetically. These investigators have done in one small volume for a rural district what Charles Booth in seventeen volumes did for the life and labour of the people of London.

The area chosen is anonymous, and villages are identified by numbers. It is stated that no special significance attaches to the survey area, and any other country district would have done as well. From various clues it is possible to identify this strip of countryside. We were inquisitive enough to locate it because we sought an explanation of the almost entire absence of any reference to the rural medical practitioner. An enumeration of resident professional workers is given—8 clergy, 14 schoolmasters, 15 nurses, and so on—but not a doctor among them. We are told that the schoolmaster is the key man in social activities in the villages. The area is said to include four infant welfare centres, and two health visitors operate in it, but we are rather left to infer that the doctor must be sought in an outside market town. Actually the *Medical Directory*, 1945, gives the names of three doctors as living in one of the large villages, and two in another, not to speak of one or two on the retired list. Possibly the active doctors were away on war service when this survey was made. At the very end we are told that the area is reasonably provided with the services of doctors on the panel, but that only one is resident, others having surgeries in the villages. Apparently the method of calling the doctor depends upon the common knowledge that he will be visiting Mrs. Jones or Mrs. Smith round about a given hour, and a message can be left at her cottage asking him to call outside his prearranged round.

From an analysis of the weekly expenditure of 45 families it appears that the agricultural labourer spends just over half a crown a week on medical services and medical and hospital insurance, the professional worker just under three shillings, and the farmer a little over four—in each case about one-third of what they spend on drink and tobacco. On drink and tobacco the agricultural worker spends one penny in the shilling, and the industrial worker spends as much on these things as he does on the clothing of himself and his family. Hospital contributory schemes are very popular, and in the rural districts of the county (Oxfordshire) their membership reaches 80%. Even in remote parishes the hospital is a subject for local pride, though there is a feeling that townsfolk gain admission more readily owing to being near at hand. Complaints are also made of the congestion of out-patient departments and the long periods of waiting, which press severely on country people, who are controlled by the transport position. One reform would be a really good ambulance system for country areas. In the county of the survey nine authorities provide ambulances, some public and some voluntary, but they are entirely uncoordinated.

The larger lesson to be drawn from this survey is that the small village—of less than 1,000 or 1,200 inhabitants—as a self-contained community is doomed to decay. It cannot survive as a healthy organism. It cannot maintain the social services. Its children must go a long way to school. It can have only the occasional visits of a doctor. It must share a district nurse. It cannot afford the overhead costs of water supplies, sewerage, and electric light. Only six out of these fifteen villages have piped water, and in two only of these are many houses connected to the mains, and only two of the villages have sewerage as well as water. In one of the larger villages the wells and springs were condemned some time ago, and here 1,200 people are dependent upon drinking-water which has to be carted from a distance, and run into galvanized cisterns placed in the streets. Every activity, economic and social, is less effective than it should be owing to the smallness of the community.

The countryman has, of course, the same right as the townsman to public services. He should not be penalized because he works in a rural area. The solution will be found partly in bringing more services under central administration, converting more private undertakings into public utilities, making water supply regional, and light and power national, with a flat rate for country and town. It is the view of the survey also that farms should be reassembled in better-planned units, re-equipped, and given adequate transport. The decentralization of urban industries will also have a marked effect on the countryside. Meanwhile better rural housing is an urgent need. Farm workers now living in isolated cottages, often insanitary, should be rehoused in good-sized villages or towns, with the bus passing the door. But preceding the new housing programme, urgent as it is, there should be public services of water, sewerage, and electric light and power; and all new houses should be built on the assumption that those services will be available immediately if not already in existence. The survey makes clear, if it was not clear previously, that there is much to be done in planning and reconstruction before the life of the countryman, either on its material or its cultural side, is likely to approach the fullness of contentment and health.

STANDARDIZATION OF DIGITALIS

Since the active glycosides in digitalis leaves cannot be isolated and weighed, the potency of digitalis preparations can be maintained approximately uniform by biological methods only. The compilers of the *United States Pharmacopoeia* were the first to recognize this officially, and stipulated that a tincture should kill a frog within one hour when injected by a dose between certain limits. A check on the normality of the frogs was provided by requiring that a certain dose of crystalline strophanthin should also be lethal in the same length of time. This requirement remained effective in the United States for many years. A good deal of criticism was levelled against it, particularly by Hatcher at Cornell University, who introduced the cat method. Hatcher thought that in providing an estimate of the therapeutic value of digitalis the cat would be better than the frog, and for many years he and his clinical colleague, Dr. Cary Eggleston, urged the desirability of making a change in the official *U.S.P.* method, without success. In the meanwhile progress had been made in this country in the use of the frog. Trevan showed that there was a great variation among frogs. If, however, a given dose was injected into each of a large group of frogs the percentage which died was related to the dose. Thus there was a ratio, which was the same for any tincture of digitalis, between the amount that would kill 70% of frogs in a group and the amount that would kill 30%. Trevan's observations thus provided a method by which different batches of digitalis could be compared, and the introduction of an international standard of digitalis leaf provided material for making the comparison. As a result the frog method was indicated as the first method of choice in the *British Pharmacopoeia*, 1932, and has been used satisfactorily since that time.

In the U.S.A. things did not go so well. No provision was made for dealing with the variation in frogs, and the end-point of the test was at the end of one hour. Since digitalis injected under the skin of the frog must first be absorbed, the use of a period so brief as one hour has the effect that differences in the rate of absorption play a great part in determining the result of the test. A freshly made tincture is absorbed quickly, whereas one which is two years old is absorbed slowly. Examined at the end of two years a tincture appears by the *U.S.P.* test to have lost a great deal of its potency. In the United States the officials under the Food and Drug Act are active in examining digitalis preparations which are offered for sale; hence the manufacturer found it necessary to guard himself against the possibility that a tincture taken for analysis after a lengthy storage period would be found deficient in potency. Some manufacturers attempted to do this by issuing tinctures which were exceptionally strong when first put on the market, so that when analyses were made some tinctures were found to be no less than three times as potent as others. Three years ago Dr. C. W. Edmunds, who had strongly defended the frog method in the United States, died, and Dr. Eggleston became chairman of the Pharmacopoeia Convention. The result has been a change in the official method of standardizing digitalis. The frog method has been dropped, and the cat method introduced instead. This change does not affect this country, but it affects the Dominion of Canada. In Canada the *British Pharmacopoeia* has long been a statutory book of standards and has enjoyed a position which it has never enjoyed at home. Canada, however, wishes to sell tincture of digitalis which will satisfy the requirements of the *United States Pharmacopoeia*, and therefore has recently made a change in the official method of standardizing digitalis and strophanthus preparations to be in accord with the *U.S.P.* Six months after April 5, 1945, the cat method will be official in Canada. Details of the new procedure have been issued by the Laboratory of Hygiene, Department of National Health and Welfare, Ottawa.

The cat method is a satisfactory way of estimating digitalis potency, but it does not give a precise measure of the therapeutic value of the sample. No method of biological comparison does this. The doctor must still determine, for each patient, the dose which he requires, however accurately the tincture may have been standardized. This being so, it may be doubted whether the greater expenditure of time and material which the cat method demands is really justified. The difficulty presented in the frog method by differences in the rate of absorption can be avoided by allowing a much longer time for absorption to take place, as is the case in the official British method. This seems adequate to secure what is the main intention of standardization—namely, to ensure that the preparations of digitalis are of uniform potency on cardiac muscle so far as can be ascertained with due regard to economy of time and labour. Since the doctor must determine by trial the dose which the patient needs, it seems unreasonable to insist on a more expensive and elaborate procedure for the assay.

THE HEART IN INFLUENZA

The nature of the myocardial damage in influenza is not well understood, for, although the clinical evidence of this is abundant, recovery is usual and few records of pathological changes are available. Winternitz and his colleagues, in their classical monograph on the pathology of epidemic influenza, do not refer to the matter. The cases observed clinically have been found during convalescence from the disease rather than in its acute phase. It is, therefore, of unusual interest to read an account of two examples of acute myocarditis complicating influenza in both of which the A virus was isolated from the lungs.[1]

In the first case the patient, a woman of 34, suffered from a mild illness which was diagnosed as "bronchitis or 'flu," and some six or seven weeks later developed an acute illness characterized by pyrexia, leucocytosis, and signs of basal consolidation. A diagnosis of pneumonic was made and sulphadiazine therapy instituted. The condition, however, deteriorated, the signs of pneumonia consolidation extended, and death occurred. Post mortem, bilateral pleural effusions were present; microscopical examinations of the lungs showed no frank pneumonia, but congestion, mononuclear-cell and lymphocytic infiltration, some polymorphs and plasma cells, but no bacteria. The chief changes were found in the heart, in which there were widespread myocardial degenerative changes of an acute type, leading to necrosis and associated with mononuclear-cell and lymphocytic infiltration. The second case was that of a man of 39, who developed an acute respiratory infection and died from bronchopneumonia after an illness of six to seven days' duration. The bacteriological findings were not considered significant, but influenza virus A was isolated. In the heart there were areas of scarring and some recent necrosis of the muscle fibres; the lesions, however, in this fatal case were limited in extent and were discovered only after careful search.

The conclusion, which the authors themselves do not press, that these cardiac results are to be attributed to the influenza virus must be somewhat critically considered. The mere fact of the isolation of the virus from the lungs cannot be taken to be conclusive evidence, and it is pointed out that the lesions in the first case had the characteristics of Fiedler's acute interstitial, or acute isolated, myocarditis —a rare condition of unknown aetiology. In the second case the fibrous lesions clearly appear to have antedated the acute respiratory infection, and the acute myocarditic changes were minimal. These observations should stimulate further interest in the search for evidence of myocardial lesions in association with influenza. At the same time the question of damage to tissues by sulphonamide drugs must be borne in mind. We are still incompletely informed as to the frequency and nature of the lesions which they may occasion, and this possible cause should be remembered where unexplained necroses occur as a complication of acute disease when these remedies are employed.

AN INTEGRATED HEALTH SERVICE

Major A. V. Franklin, R.A.V.C., has briefly described[1] how the Royal Army Veterinary Corps produced fresh and disease-free meat and milk for the armies of the Mediterranean theatres of war. Farms, livestock depots, dairies, abattoirs, and inspection services were established on the lines of supply. The work was undertaken at a critical period; it relieved pressure on shipping and home supply, and it grew into a large-scale experiment in military preventive medicine under many and varied environmental conditions. According to Lieut.-Col. H. Nelson, S.A.M.C., who was in charge of the hygiene services of the Union Defence Forces, the supply of fresh food benefited the health of the armies. He has been led by wartime experience to the conclusion that a civilian service, embracing such work as the R.A.V.C. performed, is necessary in order to combat the "very serious problem" of malnutrition and food-borne infection in his country. In an address before the South African Veterinary Medical Association[2] he proposed the appointment to the civil health departments of "veterinary officers of health," who should have charge of services concerned with the health control of food and should help in controlling the sources of infectious disease. In his opinion "the veterinary officer should become as much a member of the public health team as the medical officer of health." The theme of Lieut.-Col. Nelson's address was the oneness of the public health service.

In Great Britain the idea of integrating the medical and veterinary public health services was discussed by members of both professions more than a generation ago. It contributed to the movement which resulted in the formation of the Section of Comparative Medicine of the Royal Society of Medicine in 1923. As the *Proceedings* of the Section over the past 25 years have shown, a harmony of thought, training, and purpose unites the two professions, whereas the art and science of examination, diagnosis, and treatment of the patient are peculiar to each. Each is an authority in the application of distinctive clinical art and science to its patients. The problem is how the administrative advantages of concentrating the management of a health service in the person of one individual, who is usually a medical officer, can be harmonized with the need for making sectional work sufficiently bright in its prospects to attract other professional officers of high standing. It is an issue which may go far beyond the particular question of the veterinarian's place in public health as the public health services evolve.

We shall watch with interest how our colleagues in South Africa resolve the difficulties inherent in an integrated public health service. In Great Britain the tendency may be to leave things much as they have been: to accept the principle of collaboration between medical and veterinary officers, between Ministry of Health and Ministry of Agriculture, hoping, when a particular job has to be done, that somehow one or both will rise to the occasion, as the R.A.V.C. did in the Mediterranean theatres of war. In fact, the effect of the Agriculture Act, 1937, has been to diminish the position of veterinary inspectors in the sphere of local government, and to establish a separate veterinary service directly under central management.

MEDICO-LEGAL APPLICATIONS OF BLOOD GROUPING

The discovery of the ABO system of blood groups was soon utilized in connexion with paternity cases and also for the typing of blood-stains. But the chance of exclusion of a wrongful accusation of paternity was not very great. Even with the subdivision of A into its two common subtypes the falsely accused man has, on the average, only one chance in six that he will be excluded by the determination of the blood group. Bloods or blood-stains are divisible into six kinds only—O, A_1, A_2, B, A_1B, A_2B. The establishment of the MN system constituted a notable medico-legal advance. In paternity cases it is of about equal value to the ABO system, so that the wrongfully accused man's chances improved to 1 in 3. There are three kinds of MN blood—M, N, and MN. Combining this threefold division with the sixfold division of the ABO system, human bloods could now be divided into 18 types. A new blood group, P_1, established by Landsteiner and Levine,[1] and more recently reported on by Wiener and Sonn,[2] seems to be clear-cut enough in its inheritance, P+ being dominant to P−. Its value in paternity cases, however, is negligible, for it would exclude only one wrongly accused person in every 100. For subdividing bloods, on the other hand, it is useful; with its help the 18 kinds of blood are increased to 36.

In the short-lived days of its pristine simplicity, when Rh+ and Rh− alone were distinguished, the medico-legal contribution of the Rh system was no greater than that of P. All that is now greatly changed. If Fisher's[3] hypothesis of triple allelomorphs is established, as seems likely,[4] there will exist no fewer than 27 serologically distinguishable kinds of Rh, though some of them are rare. Wiener and Sonn in the paper quoted above discuss the medico-legal implications of Rh, confining themselves to the eight Rh types upon which there has been general agreement for some time. They point out that the chances of the wrongfully accused man have now improved to nearly 1 in 2, while the distinguishable kinds of blood are $36\times8=288$. In this last connexion, however, it must be pointed out that there is a serious limitation; Rh reactions are delicate and are applicable only to fresh, wet blood-stains.

The Rh system will make a further contribution, and there is every likelihood that new blood-group systems will be established in the near future. In a recent paper in this *Journal* Callender, Race, and Paykoç[5] described no fewer than three new antibodies, demonstrated during the course of repeated transfusions to an apparently hypersensitive patient. One of these is a Mendelian dominant, displayed by 8 to 9% of the English population. Truly, serology is making rapid strides towards justifying the opinion of Landsteiner that some day blood groups would be known to be as individual as finger-prints.

SOME EXPERIENCES OF A MEDICAL PRISONER OF WAR

BY

B. MARKOWSKI, M.D.,

Surg. Lieut.-Cmdr., Polish Navy

Between Sept. 19, 1939, and May 19, 1945, I was a Polish prisoner of war in Germany and was employed as a surgeon in prisoner-of-war camps and hospitals. These six years have afforded me unique opportunities for studying the life of prisoners of war of almost every nationality, and of making medical observations.

I became a prisoner of war when surgeon-in-chief of the Polish Naval Hospital in Gdynia. After the closing down of this hospital I was sent to labour camps in Poland, in Pomerania, and thence to the fortress of Torun, where at first only Poles were kept, but since May, 1940, also British prisoners from Dunkirk and Norway. From the fortress of Torun I was transferred to the prisoner-of-war section of the German hospital in the same town, and, after three months, with the sick men under my care, back to the fortress. In 1941 I was sent to an oflag in Prenzlau, and after three weeks to the Inter-Allied P.O.W. hospital in Neu-Brandenburg, where I worked for four years as surgeon-in-chief.

The diseases prevailing among prisoners of war were more or less directly the result of the conditions in which they lived. In most cases the front-line soldier was taken prisoner in the heat of battle, at a moment when he was applying himself to a very hard task. The very fact of becoming a prisoner, in most cases unexpectedly, caused a severe psychological shock. This blow to soldierly ambition, the feeling that their personal career was interrupted, and in many cases the realization of the national collapse, induced many prisoners to commit suicide. Such cases were particularly numerous among Polish officers and soldiers after the campaign of 1939.

With his capture two new factors appeared in the prisoner's life. These were psychological and physical humiliations. The Germans tried to humiliate their captives by constantly stressing their individual and racial inferiority. On the whole, these attempts failed to break down morale, and often gave rise to a spirit of rebellion. Prisoners were forced to salute the Germans, their good uniforms were exchanged for prison rags, their equalettes and other badges were brutally torn off, they were forced to do the most hideous sanitation jobs, they were forbidden to enter public places or to walk on the pavements, they had to listen to dirty abuse of their superiors and national leaders. They suffered, too, from hunger, cold, the absence of elementary hygienic amenities and sanitation, and exhausting physical labour. All this affected the men most severely in the first few days of their capture.

I remember the arrival at Torun of the first British prisoners of war from Dunkirk. For six days they had been travelling in sealed cattle-trucks. The heat, thirst, and starvation were such that only a few of them could leave their wagons unaided on arrival. Many of them were so exhausted that they had to be detained in P.o.W. hospitals. The beginning of the period of internment for the Russian prisoners was even worse. I estimate that about 80% of the total number of Russian prisoners of war taken in 1942 and 1943 died from hunger and cold. The majority died in German-occupied Poland in special camps in which they lived without huts, tents, or blankets, in holes which they had dug for themselves in the fields during the severe winter.

Incidence of Diseases

Such conditions tended to develop diseases of the lungs and of the alimentary canal, and fevers. Individual and racial predispositions tended to foster the development of particular diseases.

Typhus.—Of epidemics the most serious and dangerous was typhus. In 1939 there were only sporadic cases. In 1942 and 1943 epidemics of this disease spread throughout the P.o.W. camps in Poland and Eastern Germany, in connexion with which I made one particularly interesting observation. Though the number of cases was largest among the Russians, their death-rate was lower than that of other nationalities. I estimated the death rate from typhus among the Russians in our camp at 10 to 30% in spite of severe underfeeding, which in many cases was the true cause of death. Resistance to typhus was lower among the nationals of countries lying further west: thus at a hospital at Hammerstein out of 20 cases among the German hospital personnel there were 20 deaths. In the Russian prisoner-of-war camp at Hammerstein the German authorities, noticing the high death rate among German personnel who were looking after sick Russians, ordered the speediest possible disposal of the source of infection. Of course, this source was the Russians, of whom about 2,000 were at that time ill with typhus or were under observation. Within three days the German camp commander reported that there were no Russians ill with typhus at Hammerstein. This was quite true. During those three days all the sick Russians had been murdered.

Tuberculosis of the lungs caused many deaths, particularly among the Russians, Serbs, Italians, Poles, and French. Serbs and Frenchmen were especially predisposed to tuberculosis of the bones (mostly Pott's disease). Underfeeding, colds, and hard physical labour made any prospect of improvement or cure out of the question. Treatment was limited to isolation. However, as the camps were overcrowded, isolation was in practice impossible; for in 1944, in the Neu-Brandenburg camp, out of a total number of 6,000 prisoners, 2,000 had open tuberculosis of the lungs, and their number was constantly growing.

Of *diseases of the alimentary canal* there were two big epidemics—typhoid fever, dysentery, and pseudo-dysentery in 1942 and 1944–5—which ravaged the Polish, English, American, and Russians. These resulted in a high death rate, mostly due to complications in the circulatory system. Nightmarish conditions prevailed owing to overcrowding and the lack of sanitation. The sight of so many emaciated patients lying in their excrements, on a floor covered only with a thin layer of straw, was indescribably painful. In the winter of 1944–5 about 1,000 of them arrived at our hospital. They belonged to every allied nation, including many British and Americans. They had been driven for hundreds of miles, from East Prussia and Poland to Western Germany, mostly on foot. They were forced to march while starving and sick, in bitter cold weather and snow. They had to tramp on because those who lagged behind were mercilessly killed by their German guards. I have no words to describe the misery of those poor wretches, who were supposed to be protected by the humanitarian regulations of the Geneva Convention.

All these diseases—i.e., typhus, tuberculosis, and diseases of the alimentary canal—were particularly important, because of the numbers affected. Other diseases hardly differed from cases to be found in hospitals in peacetime.

Diseases due to Prison Life

I should like here to dwell a while on diseases closely connected with the conditions of life of the prisoners, and therefore comparatively rare under normal peace conditions. These are: mental diseases; frostbite; wound gangrene; diphtheria; endarteritis obliterans; severe stomach troubles.

Mental Diseases.—On the whole, the period of captivity only facilitated the development of such diseases in those already predisposed towards them. Most numerous were schizophrenia and manic depression. The weakening of the resistance of the nervous system which found its expression in abnormally strong reactions and in an inclination towards both excitement and depression could be observed among the majority of prisoners. Actual damage to their will-power or mental efficiency cannot be defined by the doctors who were themselves prisoners, but must be done by psychiatrists.

Frostbite.—In this war cases of frostbite have been particularly numerous. Some of these cases I succeeded in getting the Swiss medical press to publish in 1944. These included a case of bilateral paralysis of the radial nerve in a man who suffered only from frost gangrene of his lower extremities. Altogether, I described 37 cases of frostbite (with photographs), most of which arrived in a very advanced state of gangrene of the extremities. This led in many cases to complete or partial loss of the feet. I should like to stress here that all these cases developed, not during the actual fighting or on the battlefield, but after capture, owing to camp conditions.

The infection of small wounds on extremities oedematous from starvation caused the appearance of a rare phenomenon—*gangrene* of the skin and of the subcutaneous tissue. Such cases, resulting from putrid infection, could be observed among Soviet prisoners of war in 1942. Radical removal of the necrosed parts, together with skin-grafting, gave satisfactory results. One day late in 1942 we received 27 patients, all of whom showed symptoms of this form of gangrene; and all of them were Russians.

Diphtheria.—Our experience of diphtheria epidemics should be of particular value to British colleagues. On the Continent we used to regard this disease as peculiar to children, and we were very much struck by the fact that an epidemic spread among British prisoners of war in 1940. In that year we had about 400 cases under treatment in Torun alone. Between 5 and 15 cases were constantly to be found in the Neu-Brandenburg hospital during the last four years. Among complications were disorders of the peripheral nervous system, but deaths were few and far between.

We had special difficulties with the treatment of *endarteritis obliterans*. These cases usually arrived in hospital in an advanced stage of Buerger's disease. In one week 8 patients suffering from this condition had to be operated upon. In the early stages sympathectomy and intensive " priscol " therapy, as well as hormones (obtained from Switzerland), seemed to give satisfactory results, yet in many cases progressive necrosis forced us to amputate the affected extremities.

Severe Acute Dilatation of the Stomach.—This was another disease fairly common among the prisoners of war though rare in peacetime. It was usually caused by the intake of even a *small* quantity of food after a period of *prolonged starvation*. I have personally met with such cases only among Italian and Russian prisoners of war.

Medical Care

The organization of medical services was as follows: the personnel was recruited from medical men of all nationalities who were prisoners of war. They had at their disposal sick-rooms in the P.o.W. camps, and also special hospitals for prisoners. The head of the medical personnel was always a German, both in the camps and in the hospitals. He controlled the prisoner-doctors, but concerned himself less with treatment proper than with seeing that the prisoners were kept as short a time as possible under treatment, so that valuable man-power should not be lost to the Reich. Medical supplies, adequate at first, decreased as the war went on until they were reduced to a ridiculously small amount, and towards the end of the war we hardly got anything at all. Of special medicines, some, such as sulphonamides, were given out to prisoners, but others, like penicillin or hormones, were outside their reach. The sick-rooms in the camps were, on the whole, very poorly equipped, were overcrowded, and hardly differed at all from the ordinary prisoners' huts. Bunks in place of beds, straw in small quantities instead of mattresses, and the lack of sanitation and of running water should give an idea of how bad the conditions were. The personnel consisted mainly of untrained prisoners—male nurses, whose number was strictly kept down. Hospitals were on the whole better equipped, but as time wore on they also got worse.

Medical supplies provided by the International Red Cross improved the position, though the shortage was felt right up to the end. The patients' food hardly differed from the ordinary fare of the prisoners, and the amount of calories was much lower than what was needed. Here again the Red Cross parcels were a great help. I think that if it had not been for these parcels some 70% of the prisoners would have died from starvation. In addition to the main disease, we always had to treat complications resulting from underfeeding and cachexia.

Sights Seen in a Russian P.o.W. Camp

I happened to be in the Neu-Brandenburg camp when dinner was served. This was composed of a watery vegetable soup doled out once a day in meagre quantities. It was winter. I saw a long line of terribly emaciated Russian prisoners in rags. Their feet, blue with cold, were sometimes bare, and sometimes they wore wooden clogs. They held their mess-tins in trembling hands, numb with cold. But it was their eyes that drew my attention. They had nothing human in them; they were deeply set, shining, and fixed with an animal expression on the soup-container. They seemed to see nothing except it; they seemed not to notice that some of their comrades had fallen from exhaustion and that they were treading upon them, doing them to death by the trampling of their clogs. Their only idea was to get nearer to the soup-container and obtain their ration quickly. After this scanty fare several prisoners who had not had enough strength to wait for their turn were carried to the camp cemetery.

I have seen bodies with pieces of flesh hacked out. The flesh was cut away by starving comrades after death, sometimes even before. Yes, this was the cannibalism which the Germans denounced as a proof of the bestiality of the prisoners. It was a proof of bestiality, but of the bestiality of the Germans, who sadistically satisfied their lowest, cruellest instincts. These acts of cannibalism took place in the very heart of Germany, where, right up to the end of the war, well-fed fat Prussian peasants forced emaciated and starving prisoners to perform the hardest tasks.

The Life of P.o.W. Doctors

Though the Geneva Convention guarantees special privileges for doctors, the only practical difference was that we could, and had to, work. We had the same food rations and the same lodgings as other officers. We were entitled to two hours' walk three times a week, but of course under the guard of a German soldier. This walk was a privilege only for doctors, but doctors working in Polish oflags were not getting it. The crowds of patients, the difficulties of securing clinical and laboratory aid, the lack of assistants and specialists—all compelled us to work exceptionally hard. Yet among the Germans we found no understanding whatsoever of our problems.

In 1940 I was sent to the prisoners' section of the German hospital in Torun. It was housed partly in the hospital chapel and partly in old wooden barracks. Infectious patients, medical and surgical cases, were all herded together. In February of that year some new cases had arrived and I discovered typhus among them. The Germans at once sealed off the whole section with barbed wire and forbade all contact with the outside world under penalty of death, while I, who was in charge of all patients, including non-contagious cases, was locked up with them in one large overcrowded room. I remonstrated that in these conditions the non-infectious patients would get contaminated, but my protest was of no avail. I spent five weeks in that room among patients with high fever, many of whom died. In April of that year we were removed to Fort 14 in Torun. This fort was partly underground; it had thick damp walls, no water, and no heating. It was suitable for storing ammunition, but not for a hospital. On the first day of our work there the dampness was such that the constantly wet bed-linen dried only from the heat of our patients' bodies.

In this hospital I was given an assistant, a young English doctor, who had to work very hard and for whom I tried in vain to obtain a change of linen. At the time when help from the Red Cross was not yet in full swing we obtained much aid from the local Polish population, though the penalty for any assistance given to prisoners of war, even for such small things as the gift of a roll or article of clothing, was death; these Polish people saved many prisoners from starvation. Doctors took upon themselves the role of middle-men in supplying food. Of course, for us Poles the discovery of such activities meant death or, at least, the removal to a concentration camp.

In the Neu-Brandenburg Inter-Allied Hospital I worked not only as a surgeon but also as a radiologist. The large number of patients, including many cases of tuberculosis, necessitated frequent *x*-ray screenings. We had only one *x*-ray apparatus for about 50,000 prisoners. It was of French make, a fairly powerful unit but a fairly old model. It was set up in an old barracks with no protection of the walls, and the only cover for the doctor was a ragged apron thrown away by another hospital. When I asked for the necessary precautions against the effect of *x* rays I was told that there was a great scarcity of rubber and that German hospitals had priority. I had therefore either to work without any safety measures or to deprive my patients of *x*-ray examinations. For two years I worked without any safety devices whatever.

Another difficult problem was blood transfusion. To take blood from other prisoners, overworked and exhausted, was not practicable. Many times my colleagues and I had to give our own blood immediately after an operation to save a man's life. We did not get any stored blood whatsoever from the Germans. In this connexion I remember a Russian prisoner of war who was brought to me with an open fracture of the leg. The blood vessels were torn and he had bled a great deal. Before beginning the operation I asked the German doctors for blood for a transfusion. Their reply was that they needed the blood for German front-line soldiers, and that the patient was anyway likely to die. I said that the patient would live if the necessary precautions were taken. To show how strongly I felt about it all I arranged a somewhat theatrical scene. I performed the operation in the presence of German doctors and S.S. men, and when I had finished I asked my assistant to take about 500 c.cm. of my blood (my group happens to be O). The patient was saved, and the Germans left the operating-room without saying a word. However, later on they began to offer us some help.

In 1942, when epidemics of typhus broke out in the Russian P.o.W. camps, only Polish doctors were sent to look after them. Almost all contracted typhus, and many died, including my friends Major Dr. Borkowski, Capt. Dr. Wierzbowski, and others. In that year some 30 Russian prisoners arrived in hospital with gangrene of the lower extremities. I was asked to operate on them and to send them back to their camp, where thousands of even healthy prisoners died from cold and starvation. I refused to send them back, saying that they were human beings and must be treated as such. At this time anti-Bolshevik propaganda was at its height in Germany and found expression in studied cruelty towards Russian prisoners. Although threatened with the firing-squad, I refused to change my mind, and the affair went before the highest German military authorities, who finally agreed to leave these Russians in hospital. Owing to the firm attitude we had adopted the only place in the whole of Germany where Russian prisoners of war were treated in the same way as other prisoners was the surgical side of our hospital.

These facts show the difficulties which the doctor must be prepared to face while carrying out his own profession. But the work of a prisoners' M.O. is not confined to his professional duties. In a stalag or in a hospital the doctor is the highest ranking officer and the chief. He is the trustee and adviser of his patients in all their personal, family, and national affairs. Thus the doctor has first to heal his patients, and, secondly, as their guardian to settle the many affairs that come under his notice. Of course, the Germans took every conceivable step to make it possible for the doctors to act in the latter capacity, and actually many of the latter paid with their lives for what they did in this respect. Among my closest friends and colleagues, Dr. Zenkteller, Dr. Dudo, and many others suffered death for their work.

However, the results obtained were, in spite of all, simply magnificent. Thus, for instance, in the Inter-Allied Neu-Brandenburg Hospital, with 40,000 patients and 5,000 surgical operations in five years, the ratio of cases cured was not lower than in peacetime hospitals. Some of the recoveries of particularly grave cases, such as abdominal gunshot wounds, intestinal obstructions, operations on lungs, bladder, etc., caused not only our own amazement, but also that of German professors who from time to time visited our hospitals.

Conclusions

I should like once more to stress two points. First, the importance of our observations with regard to diseases peculiar to prisoners, particularly diphtheria, frostbite, and stomach troubles connected with starvation. While a prisoner of war I could not follow closely the international medical literature: probably experience had enlarged our knowledge of these diseases during that time. All the same, I thought it my duty to record my observations. The second point I want to stress is that such results as were achieved by us were largely due to the morale of the doctors concerned. Strength of character, professional knowledge, and stout hearts fought victoriously against cruelty and brutality. Many of my colleagues perished during the struggle, whether shot on the spot or murdered in concentration camps. Their deaths were a loud protest against war, murder, and racial and national hatred. They were uncompromising in the help they brought to the sick and wounded of every race and every nationality. And they did not hesitate to offer their lives for their ideals.

CENTRAL TUBERCULOSIS SCHEME FOR NORTHERN IRELAND

The Northern Ireland Branch Council of the British Medical Association has published a report on the need for better facilities for the prevention, diagnosis, and treatment of tuberculosis. At present Northern Ireland suffers from a lack of proper diagnostic facilities in some areas, a universal shortage of hospital and sanatorium beds, and the absence of a plan for the training and rehabilitation of the tuberculous. It is pointed out that in England there are unified schemes for the West Riding of Yorkshire and for Lancashire, as well as a scheme for Wales, and all these areas have populations larger than that of Northern Ireland, which was estimated at 1,295,000 in 1939. Northern Ireland has an annual tuberculosis death rate of 840 per million, which is below that of Wales (958), but well above that of Lancashire and the West Riding (560 and 570 respectively), and Northern Ireland is much less favourably situated than any of these areas in its proportion of beds to the prevalence of the disease, taking as the criterion of prevalence the number of deaths. While in Lancashire the percentage of beds to annual deaths is 90, in Northern Ireland it is only 56. Long waiting lists are therefore the rule at the five hospitals and sanatoria which Northern Ireland at present possesses.

The Joint Tuberculosis Council has recommended that as an absolute minimum there should be a ratio of three beds in tuberculosis institutions for two tuberculosis deaths per annum in any area. In view of the advent of mass radiography and treatment allowances this ratio may prove barely sufficient, but on this basis 1,500 beds would be required in Northern Ireland, where there are only 614 at present. The Branch Council proposes as a minimum two additional institutions. One of these would be a large modern sanatorium to be erected near Belfast (but not less than 10 miles away from the city centre). Smaller but well-equipped institutions might be built elsewhere. Whiteabbey Sanatorium, with certain structural alterations and additions, would be suitable for use as a chest hospital for Belfast and district, though not for convalescent sanatorium patients. These institutions, together with Forster Green Hospital, should go far to provide sufficient beds for all cases of pulmonary tuberculosis. Provision might be made for orthopaedic cases in conjunction with the orthopaedic scheme for Northern Ireland, or, failing this, the temporary children's hospital at Greenisland might be constructed to provide 80 to 100 beds for tuberculous children requiring orthopaedic treatment. The idea of training colonies might be developed in co-operation with the Ministry of Labour.

It is stated that the existing arrangements for notification in Northern Ireland are unsatisfactory. Medical practitioners are required to notify only tuberculous persons who are infective—that is to say, when they have reached a stage at which their chances of cure or recovery are relatively poor, when they are capable of transmitting infection to others, and when long periods of institutional treatment are necessary. It is the view of the compilers of the report that all forms of tuberculosis at any stage of the disease should be compulsorily notifiable.

Other proposals are for a larger number of tuberculosis dispensaries (the name of which should be changed to "chest clinics"), situated where possible in voluntary or county or district hospitals, and the provision of night hostels for tuberculous men and women who are homeless or lack suitable accommodation in their homes. Belfast, it is said, could with advantage provide lodging-houses for such people, with well-ventilated rooms, a verandah, and garden.

The Branch Council also calls for the efficient pasteurization of all milk supplies for human consumption as a means of preventing tuberculosis of bovine origin. About 40% of the cattle slaughtered in abattoirs in Northern Ireland are found to have naked-eye lesions of tuberculosis, and about 6% of samples of unheated milk taken from supplies delivered to households in Belfast are infected with virulent tubercle bacilli. Certain proposals are made for research, education, and after-care. Stress is laid on the need for the systematic instruction of all nurses for the certificate of the Tuberculosis Association. The teaching of tuberculosis to medical students is considered inadequate. The Branch Council recommends that they should be given a regular course of instruction in tuberculosis work, and that more facilities for postgraduate study should be available.

MEDICAL RESEARCH IN EIRE

The Medical Research Council of Ireland in its annual report gives an account of many useful investigations. The goitre problem in County Tipperary has continued to receive attention, and an analysis of the findings of a three-years experiment on the treatment of goitre in school-children by means of iodine has been completed. The indications show that the iodine has had a positive effect in arresting the development of puberal goitre. A dietary survey with special reference to the intake of iodine has been made in Tipperary, with control areas in Galway and Leix. From this work it has been shown that the iodine intake of children in Tipperary ranges from 4 to 35 gamma a day, and that families using home-made (in preference to baker's) bread have, on the whole, the higher intakes. The administration of iodine to children of school and pre-school age and to pregnant women in a number of areas has been continued, but results from this work cannot be expected for some years.

Supplies of Penicillin

The Council has been made the controlling body for the distribution of supplies of penicillin in Ireland. The arrangements are being made by two committees—one for the south of Ireland under the chairmanship of Prof. J. M. O'Donovan and the other for the west under the chairmanship of Prof. J. F. Donegan. The first consignment of penicillin arrived in Ireland in August, 1944, and from that time up to the end of the year 222 cases were treated. Arrangements have been made with the Irish Drug Association for its members to take over the storage of penicillin and its distribution to teaching hospitals in Dublin, Cork, and Galway. The work of the committees will continue until the drug becomes available through the ordinary commercial channels.

Dietary Standards

The Minister for Local Government and Public Health has asked the Council's co-operation in connexion with a proposal to establish dietary standards suitable to the Irish population, both rural and urban. Certain suggestions have been made to the Minister, and it is hoped that the proposed scheme will be working during the present year. An investigation into the typhoid carrier condition, again at the request of the Minister, has been started. Under a special grant from the Eire Parliament two workers have been appointed to carry out an investigation into the chemotherapy of tuberculosis. The question of the incidence of rickets in Dublin has also been investigated, and nearly 400 cases taken at random from out-patient departments have been examined clinically. The maximum incidence was found in the age group under 1 year, whereas in a similar investigation in the spring of 1943 the maximum came in the group 1½–2 years. There was no evidence of any appreciable improvement in the intake of milk and vitamin D. A high plasma phosphatase was taken as justification for classifying the case as one of rickets.

The Council expended during the year £7,900 on grants

Correspondence

Neurologist and Neurosurgeon

SIR,—In your sympathetic editorial (*Journal*, Sept. 1, p. 292) upon the report of the Royal College of Physicians' Neurological Committee you observe that the report has not attempted to grasp the nettle of the future relationships of neurology to neurosurgery. It is true that it does not make any proposals in this regard, and it is true also that some will have to be made and agreed if a soundly integrated body of neurological medicine is to emerge in the future.

The problem that confronts us is that of harmonizing the roles of physician and surgeon in the field of neurology, and a clue to its rational solution is given in your remark that the neurologist is "a judge who sums up and advises as to the nature, origins, outcome of an illness, and the disposal of a sick person, and *he is not the purveyor of a particular line of treatment.*" (Italics ours.)

If we are to take this view of the neurologist's functions—and it is impossible to suppose that any less comprehensive view is practicable—certain consequences follow of necessity. The neurologist must be so trained that he is competent to act over the whole field of neurological illness, and, what is not less essential, over the entire range of clinical material that may be referred to him—even though erroneously—as neurological. For no neurologist of experience will dispute that an appreciable proportion of the cases that come under his observation are not neurological in nature, but include many and diverse illnesses, somatic and psychological. He has therefore to be vigilant and reasonably competent over the whole field of medicine if he is to be expert within his own. He has diagnostically to handle neurology and whatever his colleagues may believe to be neurological, whether in fact it is so or not.

If this be a fair and reasonable statement of his position, it is clear that to exclude from his purview all clinical neurological material which investigation may ultimately show to call for surgical intervention is arbitrarily to mutilate his proper field of experience, and to do so upon no scientific basis nor in accord with any nosological categories. Such a mutilation must cripple his competence both as diagnostician and as teacher, and have unfavourable consequences for those who seek his advice as patients. Therefore the preservation of a coherent and complete field of experience is essential, and a condition of his competence within any part of that field.

How does the position of the neurosurgeon compare with that of the neurologist in these respects? Of its nature his is primarily and predominantly a therapeutic specialty, and that this is so is implicit in his training, for he passes directly from the general surgical to the neurosurgical clinic in all but the rarest instances—instances too few to invalidate the statement. He does not undertake a general neurological training, and whatever he may chance to see of what we may call non-surgical clinical neurology comprises no more than those cases that come into a neurosurgical clinic because someone outside it—in error or in doubt—happens to think them in need of surgical intervention.

The dominance of therapeutic thinking is also reflected in the routine to which these cases are commonly subjected once they enter the neurosurgical clinic. The bulk of the neurosurgeon's non-traumatic cases is made up of space-occupying lesions of one kind or another, and the great ingenuity and skill of the modern neurosurgeon have provided him with a range of diagnostic methods peculiarly his own for the recognition—or exclusion—of such lesions. These are ventriculography, encephalography, and arteriography, which are indeed amongst the major achievements of modern neurological diagnosis within their proper field. It is therefore not surprising that they should come to constitute the neurosurgeon's diagnostic weapons of choice.

The neurologist, faced by a new case, instinctively asks himself, "What is the matter with this patient?" and he is prepared to find the answer anywhere within the field of medicine. Whereas the neurosurgeon instinctively asks, "Has this patient a space-occupying lesion, and where is it?" It can scarcely be maintained that this is an ideal approach, for it carries a tacit assumption which it is neither safe nor reasonable to make as a routine. That upon occasion it has its striking triumphs few would deny, but it remains a method in which far too wide a margin of diagnostic error or failure is implicit—a margin far wider than that of the individual variations in diagnostic acumen possessed by different individuals, be they physicians or surgeons. It leads also, no less inevitably, to the undue use of the particular surgical techniques enumerated and, when these fail to yield relevant information, too often to a negative diagnosis, and to the ultimate handing over of the patient to the neurologist, to whom in such cases—if we are to be perfectly frank—it would have been better to refer him in the first instance.

All this is not to depreciate the importance of the neurosurgeon in the field of neurology. It is simply to indicate that his role is different from that of the physician; and that this point of view is not all pure hypothesis will be evident to whoever may have read Cushing's final analysis of his experience with brain tumours (*Intracranial Tumours*, Baltimore, 1932). In this we learn that some 2,000 histologically verified cases of tumour were admitted to his clinics over a given period of years, and that in addition there were also admitted 1,030 cases of "tumour suspect," and a third category of histologically unverified tumours the precise nature of which is not clear. The "tumour suspects" were comprised by cases of cerebral vascular disease, disseminated sclerosis, cerebral syphilis, encephalitis and its sequels, convulsive states, aneurysms, arachnoiditis, and psychoneuroses. Of this total of 1,030 not less than a quarter were subjected to craniotomy, with an operative mortality of 15%. It is probable that a proportion of the "unverified tumours" were of this order also.

In the event, then, it seems fair to say that, as we know it, neurosurgery is primarily and predominantly a therapeutic specialty, and one that calls for a wider range of diagnostic experience and methods than is generally possessed by those who follow it.

It may be argued that the remedy is to ensure for the neurosurgeon an adequate training in neurology; but, supposing for a moment that before embarking upon his operative career he were to undergo some such scheme of training as is foreshadowed in the report under consideration (and it is difficult to see how he would find time for it), his subsequent and inevitable preoccupation with surgical duties and interests would allow him scant opportunity of gaining over the wider field the clinical experience and judgment for which this training could be no more than a preparation.

Thus it would appear that, for the present, physician and surgeon have each a proper role, and each a different role, in neurology, and it would be as unreasonable for the physician to claim to be able to employ surgical techniques without due training and practice as for the surgeon to ask to be accepted as completely equipped to meet the wider range of diagnostic requirements it is the physician's prime duty to acquire.—We are, etc.,

F. M. R. WALSHE.
C. P. SYMONDS.

London, W.1.

Surgical Conditions in Medical Patients

SIR,—Dr. F. A. H. Simmonds's plea (Sept. 1, p. 299) for maintenance of collapse therapy when a surgical emergency necessitates admission to another hospital is a special case of a similar plea which should be made for every medical patient finding himself in a surgical ward.

Surgery is but a branch of therapeutics, and should assist and not interrupt medical treatment. Yet I have known pernicious anaemia, ulcerative colitis, and even diabetes sadly neglected because a fracture or other surgical condition has intervened.

Interruption of treatment upsets the physician also, and particularly if he is more interested in the life-history of patients with disease than in the immediate diseases (i.e., labels) themselves. All that happens to a patient under a physician's care should be the physician's concern, and he should certainly arrange to know about admissions of his patients to surgical wards in the same hospital. I can recall several acute "medical abdomens" rescued from laparotomy by this arrangement. Treatment, too, of some surgical complications is best carried out from the medical ward. The practice, for example, of admitting perforations to dietetic wards has much to commend it.—I am, etc.,

Chase Farm Hospital, Enfield. C. ALLAN BIRCH.

Domiciliary Midwifery and the Family Doctor

SIR,—I would like to record my appreciation and thanks to Drs. Logan and MacKenzie for their article on domiciliary midwifery (Sept. 1, p. 294). It is with increasing concern and dismay that we in country general practice have watched the mothers enter urban maternity home and hospital for their confinements. I use a gas-and-air apparatus, and the district nurse gives an injection of pethidine and some sodium amytal as the cervix is dilating. We are all happy and confident with this combination. Puerperal infection is very rare and neonatal infections are unknown in this area. Yet many of the babies born in urban institutions return with worrying pyogenic skin infections. The journals report successive series of severe and mortal epidemics of infantile diarrhoea in the newborn. I have never seen a case in the home of a confined woman.

It is my humble opinion that a G.P. is well equipped to handle the normal pregnancy, to diagnose and assess the abnormal developments, and to attend his patient's confinement, whether at home or in a near-by maternity institution. Small rural units for this purpose are essential, and this principle is already recognized in America.

The hours spent together by a doctor, the district nurse, and a woman in labour are essential bonds of experience and sympathy which give the doctor access to valuable family and personal matters so useful in assessing other illnesses in the family. It will dehumanize our profession, and retard the development of psychosomatic medicine by decades, if a cleavage occurs between family doctor and confined woman.

I hope the views expressed by Drs. Logan and MacKenzie will be strongly supported, and will help to decentralize some responsibility and skill back to the G.P. when plans for the new health service are laid down.—I am, etc.,

Grange-over-Sands. P. D. MULKERN.

SIR,—Drs. Dale Logan and Eneas MacKenzie have stated their case very clearly for the retention of the family doctor in domiciliary midwifery. From Dr. Mackenzie we could not have expected otherwise, as he has been a doughty and humorous champion in this arena for many years, and his views command respect. Certain points in their article are deserving of further comment.

The authors take the attitude that the methods of general practitioners cannot be bettered, and that no corporate or other specialist body has the right to assail us. Criticisms, as indicated in the report of the Royal College of Obstetricians and Gynaecologists, are not groundless, and we are not in such a strong position as the authors think, even in Scotland. They state that the increased hospitalization of expectant mothers is due to the housing shortage. I beg leave to doubt this, though partially true. It is due to the appalling lack of domestic help in the homes of our patients. This increases the anxiety of the patient, and constantly hampers the doctor's work where such help, in his own home also, is usually meagre and reluctant. Nor can we expect much more assistance from the present Government than we had from the last. The domestic-help problem has been nibbled at, but never yet tackled seriously, and we carry on in a hopelessly unsatisfactory way.

Again, the family doctor, having far too much to do, must needs practise some form or other of "interference," when if he had the time to wait another hour or two a natural labour would be completed without any instrumental aid. Who of us can deny that we quite often are forced to keep one eye on the clock and the other on the perineum? Prof. F. J. Browne's admirable book on ante-natal care gives valuable advice on mental preparation of the expectant mother for her confinement, and the soothing of her anxieties over a possibly difficult labour, by relaxation, etc. How often can a harassed and busy practitioner find time to carry out these wise suggestions? In an age of hectic rush and speed we must combat a similar attitude and approach to the leisurely art of obstetrics; but, being caught up in the general maelstrom, and with endless other duties thrust upon us these days, it is quite impossible for the average family doctor to do so.

Our "house" is, therefore, not in order: far from it. What is the remedy? More houses, certainly; social security; healthy surroundings; adequate home help for the patient *and* the doctor; and, above all, many more doctors, and smaller practices. With these ends achieved, the standard of domiciliary midwifery practised by the family doctor would very greatly improve, the criticisms of the highbrows would be confounded, and the proposed National Health Service, inevitable as it seems, might have much of its objectionable bureaucratic control "left in the discard."—I am, etc.,

Thurso, Caithness. D. W. D. MACLAREN.

SIR,—It is with diffidence that one comments on opinions expressed by such authorities as the authors of the article in the *Journal* of Sept. 1, but surely it is going too far to assert, as they do, that the Maternity Services (Scotland) Act has changed the whole future of maternity practice in Scotland, presumably for the better, without some qualification. True, the Act points the way to an efficient service, but the way is long and the goal not just round the corner, as seems to be suggested.

One wrong turning is in sight now. Few will disagree with the statement that "the relief of pain is of supreme importance to a large percentage of parturient women," but how many realize that this relief is being withheld from a large percentage of the women attended under the Scottish Act, which permits a practitioner to leave the conduct of the confinement in the hands of the midwife when he is of opinion that labour will be normal. Increasing advantage is being taken of this permission, and it is now doubtful whether practitioners over Scotland as a whole are present at more than 50% of these "normal" births. Do none of these women require relief from pain? Yet the boast is made that "in Scotland we hold —and we are supported by the B.M.A.—that no midwife should be allowed to administer an anaesthetic without a general practitioner being present." One wonders what the unfortunate women think about it, and what would happen if the midwives, who have the thankless task of seeing them through unaided, insisted on sending for help on every occasion an anaesthetic was demanded by the patient.

As matters stand at present there seems very little to choose between the English and Scottish schemes, and our brethren in the South may be excused if they still prefer their infant mortality figures to ours. The practitioner cannot expect to have it both ways. Either the State-registered nurse-midwife should be allowed to administer an anaesthetic or the practitioner should guarantee to be on hand for that purpose. Surely, the experienced Queen's Nurse, whose efficiency, tact, and discretion are so justly praised, is competent to undertake this comparatively safe and simple operation if given the requisite training. To refuse her services and at the same time to leave her patient to suffer unnecessarily requires some justification beyond the pontifical utterance quoted above.

As usual, the local authority is criticized; this time for thinking too much in terms of institutions and too little in terms of the mothers' own homes. On other occasions the crime is failing to provide the necessary institutions. No local authority sets up a maternity home just for fun when the cost per patient-day is likely to be in the neighbourhood of 15s. and receipts from patients microscopical. They do so because (*a*) so many homes are totally unsuitable for a confinement, and (*b*) so many women desire admission, not only for the benefit of skilled and continuous nursing but also for the blessed escape it offers for a short time from all household worries. "Just like a rest cure" was the description given by one harassed mother.

In some small towns there are small maternity homes where patients are attended by their own doctors, whose views on the home versus the homes for normal labours would be enlightening to the advocates of the latter. The specialists have already had their say, and it may not be out of place for the administrative officer under the Act—the M.O.H.—to make a small contribution. He has the advantage—or perhaps it would be more nearly correct to say the disadvantage—of seeing the whole picture and the somewhat difficult task of reconciling theory with practice. If "within recent years no new era has dawned upon hospital and specialist obstetric practice," that is equally true of domiciliary practice, apart from the improvement due to outside help in the shape of skilled midwife assistance and financial and other aids given by the State and local authorities, without which midwifery practice would have little attraction to-day for the average practitioner.

The M.O.H. is probably in a better position than most specialists to appreciate the many difficulties encountered by the family doctor, with whom he sympathizes and is usually on excellent terms. Such help as he is able to give is not entirely unappreciated, but his efforts are not made easier by the arrant nonsense and cheap gibes which have disfigured too many letters in the *Journal* during recent years. Is it not time a halt was called to this one-sided carping? It may sound clever, even amusing at times, but if persisted in can only cause resentment and disunity at a time when it is of paramount importance to forgo petty squabbling and uphold the dignity and decency of medicine in the public view. A word in season from the *Journal* is long overdue.—I am, etc.,

Roxburgh. JAMES R. ADAM.

SIR,—The article "Domiciliary Midwifery and the Family Doctor" is like a breath of moorland air in a crowded street. I agree with every word the authors say, and hope they are right in their suggestion that the "present urge for institutional treatment [for midwifery] is a passing phase." It is no exaggeration to talk of the harm done at ante-natal clinics by unduly alarming patients about the dangers of confinement.

I heartily endorse all they say about Queen's Nurses, especially as regards the outstanding feature of their service being co-operation between doctor and nurse. The tendency for midwives to conduct a confinement on their own, and even to give anaesthetics, breaks this co-operation and is a retrograde step.

There is a question I would like to ask with respect to institutional midwifery. Is the method of preventing mixing of babies absolutely fool-proof? In other words, when the mother leaves the maternity block is she absolutely certain she has got her own baby?—I am, etc.,

Austwick, Lancaster. T. LOVETT.

Acute Inversion of the Uterus

SIR,—I believe that there can be no doubt that Dr. Vincent O'Sullivan (Sept. 1, p. 282) has discovered, and used with striking success, a new method of reducing the recently inverted uterus, and that it is a simple method likely to be of great value. As long ago as 1858 Dr. Tyler Smith introduced the plan of exerting on the inverted uterus "gentle and long-sustained" pressure by distending with water a rubber balloon placed in the vagina. With Dr. O'Sullivan's method the distended vagina would assuredly exercise pressure on the uterine surface more diffusely and presumably more effectively than would a rubber ball. Again the amount of pressure so exerted would definitely exceed that attained by the ordinary method of vaginal douching, which in itself had been associated, by those of us who have had cases of "spontaneous" reposition, with the vaginal douching prescribed as a cleansing measure in preparation for manual or instrumental pressure. Dr. Herbert Spencer (*Obstet. Trans.*, 1905, p. 227), in the discussion on a case of spontaneous reposition reported by Dr. Robert Boxall, agreed with the view that "possibly the gentle pressure of the stream of water had caused it." It would appear, therefore, that someone should have devised the method which Dr. O'Sullivan was astute enough to spot when it occurred fortuitously. In view of the rarity of this dangerous complication of parturition, he is fully justified in reporting an experience based on two cases only, in order that the method may be tested further by others as soon as possible.

It is vitally important to note and remember that he lays stress on the obligation of delaying the use of even this gentle measure until "shock is controlled." Finally, one cannot refrain from praising the magnificent feat of conservative surgery achieved in his second case.—I am, etc.,

Laugharne. MILES H. PHILLIPS.

SIR,—I was interested in the article by Mr. J. V. O'Sullivan (Sept. 1, p. 282), since in the East from very ancient times the urgency of acute inversion of the uterus has been recognized and countered by the postural method of immediate suspension of a patient in the almost vertical position by securing the feet to a pole (usually a bamboo), or by placing the patient, head downwards, on an acutely inclined plane made of rough-hewn logs. Thirty-five years ago I saw this method in use in the Chinese quarter of Bhamo in North-East Burma, and again later in a Bengal village. I was informed that such suspension for an hour or more was always successful, and a few years later I was able twice to demonstrate its efficiency in the labour room of the Eden Hospital, Calcutta, by just dropping the patient into the very highest Trendelenburg position and gently compressing the inverted uterus.

The proposal of Mr. O'Sullivan sounds ideal where the means exist, but maybe an occasion will arise in general practice where the tried wisdom of the East can be applied—that is, the use of a double clove hitch round the ankles attached to the bottom of a bed which is almost stood on end—a position that allows warmth, postural replacement, morphine, and rectal saline.—I am, etc.,

London, W.1. V. B. GREEN-ARMYTAGE.

SIR,—I read with interest the article by Mr. J. V. O'Sullivan; his method of treatment should help materially to reduce the high mortality of this rare condition. But it seems to me that in teaching the treatment of acute inversion far more emphasis should be placed on the *immediate* reinversion of the uterus *whatever* the condition of the patient. As Mr. O'Sullivan states in his record of Case I, on reinversion of the uterus "the signs of shock rapidly disappeared." To support the argument it may be of interest to mention three cases which I have had the unusual experience of seeing.

The first occurred after a normal pregnancy and first and second stages of labour. There was some delay in the delivery of the placenta, and Credé's expression was attempted without success. It was then noticed that the patient was becoming very restless and distressed, and she was returned to bed. I saw her about half an hour after the onset of the collapse, and we found she had then a complete inversion of the uterus, with the placenta attached to the fundus. She was profoundly shocked, but an immediate attempt was made at reinversion. The placenta was stripped off without difficulty, and it was found quite easy to replace the uterus following steady pressure with the finger-tips. No anaesthetic was given. The immediate improvement in the patient's condition was remarkable. No other treatment was given, and she made an uninterrupted recovery.

The second patient was admitted with a complete inversion some two hours after the condition developed; and in extreme shock. An attempt at reinversion was not successful (probably with Mr. O'Sullivan's method it could have been done quite easily), and she was desperately ill for three or four days, eventually reacting to the antishock measures adopted. The uterus gradually involuted, and eventually reinverted spontaneously some two months later while the patient was still in hospital.

The third patient was also admitted about two hours after collapsing, and she was moribund on admission. The uterus was completely inverted, with the placenta attached to the fundus. In view of her moribund condition an attempt was made to treat the shock first, but she was dead within a quarter of an hour of admission.

Surely the treatment of any case of shock is to treat the cause first if this is known. Mr. O'Sullivan recommends immediate replacement "before shock develops"; but will it not usually be found that shock appears at the same time as the inversion develops, due presumably to traction on the sympathetic system, and so cases are unlikely to be seen in which primary shock is not already present? As he states in his article, the degree of shock is "out of all proportion to the amount of blood lost."

It seems likely that, if this simple method were used as the first treatment to combat the shock, few other measures would be required.—I am, etc.,

Rothley, Leicester. A. M. FERENS BATTY.

Removal of the Wrong Eye

SIR,—Dr. H. M. Traquair (Sept. 1, p. 300) writes to inquire whether the removal of the wrong eye is to be regarded as a "hypothetical possibility rather than as an actual fact," and goes on to say that he has never heard of a case. I have personal knowledge of one such case, for I knew the surgeon well and the hospital where it occurred, and, indeed, all the subsequent story of the bitter remorse of the surgeon and the efforts taken to alleviate, so far as possible, the terrible blow to the unfortunate patient, who was totally blinded.

The possibility of such an accident is always present when there is no external evidence of disease in the affected eye such as may be the case in an intraocular tumour. I always practised and always taught students to practise, as a routine measure, the simple expedient of plainly marking the brow above the eye to be excised before the anaesthetic was started.

I know of another case, though I had no personal acquaintance with it, where the surgeon had just started to remove the wrong eye, but was stopped before any serious harm had occurred, by his assistant, who expressed a doubt on the matter. A hasty reference to the notes showed that the assistant was right, and a stitch or two in the conjunctiva, which I assume required a little explanation, sufficed to avert a major tragedy.

Dr. Traquair finds it difficult to imagine that a tragedy of this nature could occur without its being recorded in print; but surely it is scarcely a matter for surprise. The surgeon would obviously refrain from advertising his carelessness in the medical press, and most assuredly would adopt every means in his power to prevent the case appearing in a public court.—I am, etc.,

London, W.1. ARNOLD LAWSON.

Penicillin: Need for Control

SIR,—Supplies of penicillin will soon be available in unlimited quantities, and I feel it is timely to ask as a venereologist if the dangers of the uncontrolled issue of this preparation have been considered. The salutary lessons of the "just a couple of tablets" cure of gonorrhoea during the days of the sulpha series seem to have been forgotten in our new enthusiasm for the "just a couple of injections" in the present penicillin era, if one can judge not only from the reports in the non-medical press but also, unfortunately, from the large number of uncritical reports published in our own journals. Let it be remembered that now syphilis is included, and "cure" is being claimed long before any real assessment of cure is possible. Let me therefore stress the following points.

1. While penicillin undoubtedly kills the gonococcus and *Sp. pallida*, the *diseases* caused by these organisms in the human body bring about vast pathological and humoral changes which of necessity introduce factors which interfere with the lethal properties of the preparation.

2. Dosage is at present empirical, and failures are admitted even by the most enthusiastic. It is interesting if one compares the percentage cure rate in gonorrhoea claimed in the early days of sulphonamides with those now claimed for penicillin.

3. It follows from 1 and 2 that patient evaluation of results over many years, paying more attention to our failures than presenting glowing percentage cure tables, is necessary if we are to disseminate real knowledge and counteract in the lay mind the pernicious effects of articles on "wonder drugs" in the non-medical press.

4. Venereal disease by its very nature tends to become the happy hunting-ground for uncontrolled therapists if an added element of secrecy is thereby obtained. Can we imagine the chaos with the arrival of "tabs. penicillin"?

5. Unlike the sulpha drugs and arsenic, penicillin being non-toxic can be used with impunity.

Enough has been said to indicate the necessity of pressing for control now before penicillin supplies are released, and I leave it to others to point out the dangers that will certainly follow the improper use of penicillin in other specialties. Finally, this letter is not written to belittle in any way the remarkable properties of penicillin or the hope that it gives for the future treatment of venereal disease.—I am, etc.,

Streatham, S.W.16. F. L. LYDON.

Posture during Acute Rheumatic Fever

SIR,—Many textbooks on medical treatment declare that during the acute stage of rheumatic fever with cardiac involvement the patient is best nursed lying in bed without pillows, and that these should only be gradually added when there are signs of improvement. This method, however, seems to me to be a mistake, and even to embarrass the heart in the very way it tries hopefully but incorrectly to avoid.

We all know that a patient with cardiac failure will adopt the sitting posture in preference to lying down, before signs of dependent oedema or ascites have yet developed. Experimentally, this subjective feeling of orthopnoea has been shown to have partly a haemodynamic explanation, and many workers (e.g., "Cardiac Output in Man by a Direct Fick Method," John McMichael and E. P. Sharpey-Schafer, *Britsh Heart Journal*, 1944, **6**, No. 1, p. 34) give figures showing that the cardiac output may be increased by as much as 33% in changing from the erect to the supine position. Therefore in grave cases of cardiac distress it would be much more appropriate to nurse the patient sitting up in bed, in order to give the heart the least possible burden, rather than lie him down, increase the heart's work, and so harass it.

I would like humbly to suggest that the time-honoured, though unfortunately inaccurate, method of nursing these patients without pillows be reconsidered and a more rational approach made to a small but nevertheless significant measure in the therapy of a widespread and distressing malady.—I am, etc.,

Hampstead, N.W.6. LEON RADCLYFFE.

Poisoning by Accidental Drinking of Trichlorethylene

SIR,—Two cases of poisoning by accidental swallowing of trichlorethylene were described in your pages on Aug. 18. May I add a record of another case in which the quantity swallowed (1/2 oz.) was the same, but the effects less severe. Perhaps this was owing to delayed absorption by the stomach, the poison having been taken at 10.15 a.m., immediately after a large breakfast, on April 15, 1945. I saw Miss X, aged 15, an hour later. Her relations had tried, but failed, to make her vomit. I washed out her stomach, and she aided in this manœuvre by vomiting copiously. She was then complaining of dizziness, and numbness of hands and feet. The knee-jerks and biceps-jerks were equal and normal, but she could not hold anything firmly. At 11.30 a.m. she complained she could not hear very well; and at this time she also had incontinence of faeces and began to cry for her mother. She did not lose consciousness, but appeared dazed. She had complete amnesia of the interval 11.30 a.m to 2 p.m. on that day. During the next 24 hours her appetite was poor, but after that she was perfectly fit. A blood count taken on April 18 showed no abnormality.—I am, etc.,

NORA NAISH.

Pasteurization of Milk

SIR,—It would seem from a perusal of the recent correspondence on this subject that most members of our profession still regard good health as being due to the absence of pathogenic bacteria, and all the evidence, both recent and remote, that good health is due to a way of life is ignored. That vigorous health can usually be obtained by following certain simple natural laws is forgotten by all but a notable few. Such things as cleanliness, or the quality of the animals we eat or which provide us with milk, are matters that only cranks bother about. And so we have the present situation in which the general public is told that, although part of its diet consists of sewage, it does not matter in the least so long as that sewage is pasteurized!

In fact, as the guardians of the people's health, we are now advocating the spending of millions of pounds on apparatus for this purpose of sterilization. "Then," we say in effect, "you may eat any filth you like, whether the produce of a cesspool or the fluids which have come from the disease-ridden body of a tuberculous cow, and provided you pasteurize it first it will keep you in health and supply you with the food you need! The fact that it is brimful of waste and toxic materials and contains billions of dead disease germs does not really matter, for it has been put through a special magical process that turns the foulest refuse into excellent food, and in these days of shortage what could be more commendable? "

Since the conditions of milk production in this country are so deplorable it will no doubt be necessary, *as a purely emergency measure*, to institute widespread pasteurization. But in so doing let us make it abundantly clear, with the utmost publicity, that such pasteurization is a temporary procedure, until such time as we improve the quality of our milk production and remove the ignorance of many of those who handle it. If the emphasis is put on pasteurization, as at present, we shall only succeed in further debasing our food supply, whereas a campaign aimed at the enforcement of scrupulous cleanliness and an insistence on giving our cattle the same care and hygienic treatment we give our racehorses would result in a healthy milk supply, free from disease and of high food value.—I am, etc.,

Slough. H. TUDOR EDMUNDS.

Why "Hyperbaric" and "Hypobaric"?

SIR,—To the unlearned these unnecessary words with opposite meanings are dangerously similar: if they have been coined in order to display their inventor's erudition he should consult the friend (or enemy) of his schooldays, "Liddell and Scott," which translates ὑπερ-βᾰρής as "overloaded; overweighed; exceedingly heavy," and ignores the possible existence of such a word as ὑπο-βᾰρής. In the interests of accuracy and of our patients' lives let us stick to "heavy" and "light," at any rate when talking of spinal anaesthetics.—I am, etc.,

H. WILLIAMSON,
Lieut.-Col., I.M.S.
The Viceroy's House, New Delhi.

Press Publicity

SIR,—Having been the subject this week-end of much unwanted and unexpected publicity may I say a few words on the particular circumstances. As I have the honour to serve on the Journal Committee it is perhaps only right that I should also add something on medical publicity in general, to let my constituents know my attitude on the matter.

First of all I should naturally have preferred to avoid all interviews, etc., but when the first reporter, on my asking why he wished to see me, said that I must know that I was the first doctor in this country to put in print that he practised euthanasia, it was obviously necessary for me to try to make him understand the difference between that and giving a dose of morphine to a person apparently dying from coronary thrombosis, even though I thought it unlikely that he would wake up again. This I found no easy job, and the few remarks made in the Press about coronary thrombosis show that I succeeded very poorly.

One difficulty about living in a house where my family have practised medicine for nearly a century is that I myself can have few personal secrets. Similarly, in a small town where intermarriage is common it is practically impossible to hide the identity of any patient about whom one may write if people are really anxious to identify him—which was never anticipated when I wrote my paper. My patient was, however, quite willing for me to mention his case if it would, as he said, save anyone a minute of the agony he had endured till the intravenous morphine cut it short.

It seems that great numbers of readers are interested in names and other personal details, and this leads to perhaps the most objectionable side of newspaper reporting, especially from the medical point of view. The subjects discussed in my paper were of the highest possible medical, human, and social importance, and I tried to treat some of the problems connected with approaching death simply and scientifically, and yet also as a man, a citizen, and often a friend. There is vast scope for much fuller and more authoritative treatment of the matter, but if every effort is to be the subject of general publicity, and if the more striking occurrences, which every doctor must meet and which so often point the way to unsolved problems, are to be sensationalized in the way some reporters seem to wish, the efforts will be few and progress slow—to the inevitable loss and suffering of the public.

When once an article has been published it is open to any newspaper to make whatever use it wishes of its contents so long as comment is reasonable and fair and does not amount to wholesale plagiarism. Personally I welcome any effort by the general press to stimulate interest in medical matters among their readers, but, as certain extracts from my paper showed, it is only too easy to take sentences out of their setting and so give a distorted or sensational view of what has been written. It seemed to me that reporters have a leaning in this direction which is not, on the whole, shared by their editorial staffs; indeed the last telephone call of the day—at 1.5 a.m.—was from an editor who wished to confirm that what had been written would not offend any ethical rules or be likely to cause me annoyance. In the end he left it all out, and so did several other papers that were contemplating some references to my article.

It is perhaps a curious commentary on public taste that, though various papers gave different excerpts from my article, none of them made allusion to what was perhaps the most dramatic as well as the most scientifically based section of all—the use of cardiazol ephedrine in asphyxia neonatorum. Apparently the public is more interested in the tragedy of death than in the more wonderful drama of birth, just as efforts at destruction in war have hitherto greatly exceeded efforts to establish peace.

I have not seen all the newspaper references, and there have been things which I regret; but looking back I cannot but be struck by the amazing pertinacity of the pressmen to get what they want—however little some of their methods may commend themselves—and also by the genuine effort of all the editorial staffs with which I came into contact to do the right thing by the doctors, while, of course, also giving their readers what they think they would like. Where there is such a feeling of good will I feel sure that doctors should realize it and try to develop it, not for personal or professional ends, but to help educate the public in some of the facts of health and medical practice: its needs, its achievements, and its opportunities; its weaknesses and shortcomings; for it is only by cultivating public opinion that Government intervention can be prevented from specious and hasty policies and guided into fruitful channels and wise legislation.—I am, etc.,

Winsford. W. N. LEAK.

Doctors and the Social Trend

SIR,—May I through you acknowledge the unanimous support of those who kindly wrote to me on the subject of my letter which appeared under the above heading on Aug. 18. Judging by the letters printed in the issue for Sept. 1, the others appear to have written to you, Sir.

Contrary to the opening statement in Dr. W. B. Pemberton's letter, many believe we went to war to *preserve* social trends and to overthrow all power exerted against the right of peoples to evolve their institutions by means of freely elected representatives. It is absurd that Dr. Pemberton's most ignorant uncertified patient should have as much say in the determination of our future institutions as his doctor, but, for all that, I remain a democrat in company with the majority. Also, in spite of Dr. Kate Harrower's remarks one cannot fly even Conservative "colours" in the face of a good democracy. She will note that the reason Mr. Churchill "has not been swept very far aside" is because he, in a statesmanlike manner, has abandoned the tone of his electioneering and made it clear that he does not regard the function of H.M. Opposition as obstructionist or necessarily uncooperative. His example might appeal to some people who find themselves in opposition to the Government outside the House.

While Dr. Pemberton is accusing me of defeatism for failing to emulate the miners and dockers (General Strike, 1926?) Dr. Norman P. Henderson on the opposite page expresses the opinion that "doctors have never desired to oppose the wishes of the public." But all this unpractical talk about our "unassailable position" and united opposition to "dictation" clearly threatens opposition to the wishes of the public. It is as reminiscent of an aboriginal war dance as any "example" we have had from "Australia and New Zealand." It may be "heartening" to a few warriors, but it is the despair of those who hope to retain public sympathy.

Dr. Henderson states that the Government *will* "demand a full-time salaried service," and at the same time thinks it "unfortunate" that I should have so far assumed "the rôle of a prophet" as to venture the suggestion that we *may* now have to face such a service. After all, as he says, "most of us are aware of the Labour Party's proposals for a National Service for Health." The point is, Are we going to consider any such proposals from the accredited representatives of the people in the dual role of public servants and expert advisers, or are we already challenging the Government as the unrelenting champions of minority interests? It would seem advisable to announce a broadly co-operative attitude at once, and reserve any opposition for matters of detail later. We are not sufficiently united or strong to stage a retrial of the broad issues which were settled at the General Election. As I pointed out, we could not hope to succeed where Mr. Churchill failed. Whereas the Government might go far to meet us over important details in return for our good offices, its continuance or fall depends, as Dr. Henderson intimates, on its ability to prove that it has promised "something it was sure it could carry out." What people like Dr. Pemberton propose is practically mob law. They wish to oppose the Government to a greater extent than is open to their representatives in the House of Commons. That sort of opposition would indeed invite comparison of doctors with the very worst elements among the miners and dockers.

It is to be hoped that before long we shall have a really statesmanlike pronouncement from the B.M.A. parallel to Mr. Churchill's declaration of opposition policy in Parliament. In the meantime may I once more counsel a larger view of the profession's position in this democratic island and beg that it shall not be compromised further by obstructionist activities.—I am, etc.,

Eye, Suffolk. J. SHACKLETON BAILEY.

SIR,—Dr. Norman P. Henderson writes (Sept. 1, p. 302): "In the event of the full-time [medical] service failing (as it has to a large measure in Russia) . . ." It would be interesting to know on what grounds he bases the statement in parenthesis. All I have read of the socialized medical services in the Soviet Union, in both Russian and English, written by both Soviet and British doctors, suggests that the Soviet health services have been very successful, and, in particular, have tremendous accomplishments to their credit during the war years, which would hardly have been possible with any other form of organization. All the articles which have appeared in the *Journal* confirm this, and do not in the least bear out Dr. Henderson's statement.—I am, etc.,

Nelson, Lancs. T. D. CULBERT.

Ludwig's Angina

SIR,—Mr. Hamilton Bailey (March 17, p. 384) criticizes an article on Ludwig's angina (March 3, p. 295) by Majors John Farr and E. D. Stanhope in which they advocate endotracheal anaesthesia. I suggested this method to them, although I was not associated with them for the series discussed in their article.

The answer to Mr. Hamilton Bailey's theoretical objections is that the tube *does* go in! It is not necessary to have the patient deeply anaesthetized before a tube can be passed beyond the vocal cords. It can be passed under nitrous-oxide-oxygen anaesthesia. No anaesthetist, however experienced, would claim to intubate by the blind method in 100% of cases. I will, however, admit the theoretical point (and time will tell if it is also a practical one) that it may not always be possible to intubate under vision in these cases; but surely that is no reason for avoiding any *attempt* at this method of anaesthesia, since—to quote Mr. Hamilton Bailey—"Obviously, if the larynx is intubated the principal danger of the condition and the anxieties connected with the anaesthetic fade into insignificance."

One cannot estimate the degree of oedema of the larynx without looking at it, but I am under the impression that most of the obstruction in Ludwig's angina comes from the swelling of the tongue and floor of the mouth. No obstruction has been felt as the tube passes into the larynx, and no difficulties from laryngeal obstruction have been noticed on removing the tube at the end of the operation. The following procedure has proved satisfactory in a small series of cases.

In accordance with Hewer's dictum that *any* patient is improved by the inhalation of oxygen, the face-piece of the Boyle machine is applied and oxygen given. Gradually nitrous oxide is added until automatic respirations are established, and, if the condition of the patient requires and warrants it, a little trilene. The Magill tube is then passed by the blind method, and anaesthesia and the operation continued at leisure. A tracheotomy set is always at hand, as stressed by Major Farr.

I have not had to use a laryngoscope in any of these cases, but it was envisaged that, should intubation fail, the surgeon would have to be prepared to do the operation immediately under gas-and-oxygen anaesthesia. Finally, intravenous anaesthesia is contraindicated in all cases of respiratory obstruction, whether the mouth can be opened or not.—I am, etc.,

J. H. WEST,
Major, R.A.M.C.
East African Command.

Means for Keeping up the Population

SIR,—Much has been said and written recently on the subject of the prospective decline in our population. May I put forward the following outline of a scheme for dealing with the problem.

1. Set up crèches in every district, where mothers may, for a reasonable fee, leave their young children in the afternoon. This would enable the mother to enjoy some recreation, which would broaden her outlook, thereby making her a better parent. It would also enable the expectant and nursing mother to have that "rest in the afternoon" which at the present day is usually merely a textbook phrase.

2. Provide "domestic helps," adequately trained and paid by the State, for a certain number of hours each day from two weeks before till three weeks after confinement in a normal case—more where special conditions demand it. This care of the mother in the puerperium would also result in a vast reduction in the number of gynaecological cases which fill our hospital beds and (I may add) lower the efficiency of the patient as a mother.

3. Let us tackle the question of septic abortion. If the figures of the mortality due to this condition could be assessed I feel sure they would be comparable with the maternal mortality from all other causes combined. Moreover, for every fatal case there are many more women rendered chronic invalids (and sterile) for life. The majority of these septic abortions are not performed by professional abortionists on unmarried women or women with husbands in Burma; they are effected by the women themselves—married women with husbands at home. The risks they run must be brought home to them by some form of publicity similar, if modified, to the V.D. campaign now in progress. Thus the lives and health of thousands of women in the prime of life may be saved.—I am, etc.,

Rotherham. ANNE M. TOMS.

Taking the Waters

SIR,—The therapeutic value of spring or spa water was originally on account of its powers of rejuvenation, and the sanctity of the holy wells in this country probably goes back to the days of the megalithic civilization of some two thousand years B.C., which derived its ideas from Egypt or Sumer via Crete and the Iberian peninsula. The alleged healing wells were not discovered by the medical profession but by the pilgrims who thronged them as places of sanctity, which thus attracted the doctors. Harrogate waters, for example, were not discovered in the 16th century; the original patron saint was possibly the Egyptian Horus the Child—according to the views of the late Dr. Rendel Harris and others—in his capacity as the deity of rejuvenescence. Later he was supplanted by St. Mungo (with St. Robert), who, as a "twin," possessed the powers of his predecessor, as do all Dioscuri or Heavenly Twins.

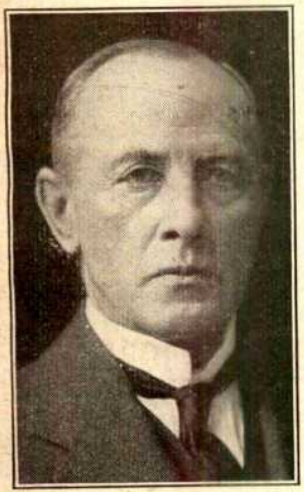
The holy well is generally the fountain of eternal youth, whose popularity has now been supplanted by the glands of the monkey. Prof. Stanley Davidson's report on the negative value of spa waters—the subject of an annotation in the *Journal* of Aug. 25 (p. 259)—instances how long religious superstition can remain in the minds of so-called educated men and women. It is said that the Phoenix rejuvenated himself not only in the fount of youth but also by fire. Possibly he was also aware of the doubtful value of sacred spa water and utilized an alternative and more reliable method.—I am, etc.,

Bournemouth. LOWELL WEBB.

Obituary

J. T. WILSON, LL.D., M.B., F.R.S.

We regret to announce the death on Sept. 2 of Emeritus Professor J. T. Wilson, the distinguished anatomist who held the Challis chair of anatomy in the University of Sydney for 30 years and the chair of anatomy at Cambridge for 14 years, and was president of the Anatomical Society of Great Britain and Ireland in 1924–5. He was looked up to with affection and regard by generations of pupils and younger colleagues in this country and in Australia.



James Thomas Wilson, son of Thomas Wilson, was born at Moniaive, Dumfriesshire, on April 14, 1861, and studied natural science and medicine at the University of Edinburgh, where he, like many others, came under the powerful influence of Sir William Turner, the professor of anatomy, who was quick to recognize and encourage men of promise. Wilson graduated M.B., C.M. in 1883, and after a house-surgeoncy at the Edinburgh Royal Infirmary served for a year as demonstrator of anatomy in the university. In 1887 he left for Australia to become demonstrator of anatomy in the newly established medical school of the University of Sydney, and in 1890 was elected to the professorship of anatomy created in that year. Thenceforward until 1920 Wilson built up and consolidated the Sydney school of anatomy and made great contributions to knowledge. His work in the comparative anatomy of Australian fauna and in embryology was recognized by his election as F.R.S. in 1909, and the University of Edinburgh conferred on him its honorary LL.D. Public duties also claimed his time and energy; he was given command of the Australian Intelligence Corps before 1914, and on the outbreak of war undertook the organization of the censorship in New South Wales. In 1920 he returned to Britain on accepting the chair of anatomy in the University of Cambridge, where he was elected a Fellow of St. John's College and received the M.A. degree *honoris causa*. For the next 17 years he represented the Australian universities on the executive council of the Universities Bureau of the British Empire. His 14 years as head of the anatomy department at Cambridge were happy and fruitful. On his retirement from the chair at the age of 73 he was made professor emeritus and continued to live in Cambridge, where he delighted to welcome visiting scientists and medical men from Australia.

Prof. Wilson was a member of the Council of the Royal Society in 1921–3, and an honorary member and past-president of the Linnean Society of New South Wales. He was also an honorary member of the Royal Society of New South Wales and an honorary Fellow of the Royal Society of South Australia. He joined the British Medical Association in 1894, and held office as vice-president of the Section of Anatomy at the Annual Meeting in Glasgow in 1922. He was president of the Cambridge Philosophical Society in 1924–6.

* * *

Dr. James Powell, of Sennybridge, Breconshire, who died on Aug. 2, was born at Danygraig, Aberdare, and was educated at Monkton House, Cardiff, and Christ College, Brecon. He received his medical training at Cardiff Medical School and at St. Mary's Hospital, London, qualifying M.R.C.S., L.R.C.P. in 1911, and later taking the D.P.H. of Oxford. Dr. Powell first practised at Clydach Vale, and later was assistant M.O.H. at Aberdare; from 1919 he carried on an extensive practice at Sennybridge. He joined the B.M.A. in 1912, and was a member of the Local Medical War Committee and the Breconshire Insurance Committee. He was medical officer of the Sennybridge St. John Ambulance Brigade and Nursing and Cadet Division.

Dr. W. S. Tresawna died on Aug. 21 at his home in Abergavenny, where he had practised (save for the war years 1914–18) since he joined the late Dr. Gamble in partnership 36 years ago. His death robs the district not merely of a highly efficient practitioner and senior M.O. to the Royal Victoria Hospital, but of a colourful personality and of a very popular all-round sportsman. William Samson Tresawna was born 66 years ago in Cornwall, and was educated at Probus and at Sidney Sussex College, Cambridge. He went to St. George's Hospital, London, for his clinical work, and qualified as M.R.C.S., L.R.C.P. in 1905, proceeding to the M.B., B.Ch. at Cambridge in 1907, after holding the usual resident appointments at St. George's. He was a really good cricketer, though handicapped by myopia—but for which, his friends believed, he must surely have got his Blue. He played many fine innings for the Cornwall County eleven, of which his elder brother was for some years the captain, and had the knack of turning out for an occasional game, wholly short of practice, and gathering a century in glittering style; he was also a fine fielder. In addition, he was a good golfer and a keen rider to hounds. He was for a long time a battalion medical officer in the 1914–18 war, and was mentioned in dispatches. A true Cornishman by descent, his handsome hawklike mobile features, always alive with fun and humour, his wavy black hair and dark complexion, all made it easy in his student days to believe the currently accepted view that a strong Phoenician strain tinges the blood of the old Cornish families. Dr. Tresawna married Vera, third daughter of the late Dr. Charles Tuke (one of the three brothers who carried on the very well known private mental hospital at Chiswick House). She survives him with four daughters and one son, Lieut.-Col. R. Tresawna, D.S.O., of the D.C.L.I.

Dr. Arthur Walker, who died on Aug. 22 at the age of 73 years, is widely mourned in Weston-super-Mare musical circles, in which he was well known and appreciated as honorary secretary of the orchestral section of the Music Club and as a 'cellist with the Red Triangle Orchestra. From the Manchester Medical School he qualified M.R.C.S., L.R.C.P. in 1894, and after house posts, service as ship surgeon, and other appointments he settled in general practice at Glossop in 1898. Having later developed a keen interest in ophthalmology and acted as school oculist to the Glossop Education Committee, he successfully applied in 1923 for the position of county oculist for Somerset, and he came south to reside in Weston-super-Mare. It was a most happy appointment for the Somerset school-children. He was a family man, and thorough and self-sacrificing in all his duties. In his private practice he was so much the beloved physician that more than 20 years after leaving Glossop many of his old patients kept up their grateful friendship with him.

Dr. Arthur Hamilton Lowe, who died in retirement at Southbourne, Hants, on Aug. 29, had been for ten years county medical officer and tuberculosis officer for Kesteven, Lincs. The second son of G. M. Lowe, M.D., he was born at Lincoln on Sept. 13, 1869, and from Lincoln Grammar School went to study medicine at the University of Edinburgh. He graduated M.B., C.M.Ed. in 1893 and took the Dublin D.P.H. in 1911. Before entering the public health service Dr. Lowe had served as senior house-surgeon at the West Ham Hospital and resident medical officer at the Newark Hospital. During the war of 1914–18 he held a commission as temporary captain, R.A.M.C. He was chairman of the Kesteven Division of the B.M.A. in 1934–5.

A correspondent writes: The numerous friends of Surg. Cmdr. John Davies will have heard of his recent death with a deep sense of personal loss. At the outbreak of the war he immediately volunteered for active service, and obtained a temporary commission in the R.N.V.R. He was soon employed on neuropsychiatric duties, for which he proved to be particularly gifted, and subsequently served as a neuropsychiatric specialist in naval hospitals both in this country and in Egypt. "Jackie" Davies was a doctor of quite outstanding capacity, well able to hold his own with any medical specialist. Consequently, throughout his Service career his opinion was repeatedly sought in general medical as well as in neuropsychiatric cases, and this involved a great deal of extra work; but he always appeared to be eager and willing to help and never complained. His small, slight physique, thick grey hair turning white, and pleasant Welsh voice made him a memorable figure. He was an admirable messmate, and invariably equable, active, and cheerful. Few men can have worked harder during the war, been more popular, or have done a better job. And when, in the spring of this year, he learnt that he was suffering from malignant hypertension, he faced the news with great courage, and so continued to the end, greatly fortified by his brave and devoted wife.

Dr. **H. Douglas Smart**, who died on Aug. 29 at Barnham, Sussex, was school oculist to the West Sussex County Council, honorary ophthalmic surgeon to the Victoria Hospital, Romford, the Forest Hospital, Buckhurst Hill, and the Jubilee Hospital, Woodford, and also oculist to the Ilford Borough Council Education Committee. Born in Bermondsey on July 14, 1880, son of Dr. David Smart, he was educated at Merchant Taylors' School and Guy's Hospital, qualifying in 1903. He obtained the M.B.Lond. degree in 1904, the B.S., with honours, a year later, and proceeded M.D. in 1906. During the war of 1914–18 he served as M.O. to the 8th Batt. Lincolnshire Regiment and as second-in-command of the Cannock Chase War Hospital, reaching the rank of major and winning the Military Cross. After a period of practice in partnership at Shelley, Huddersfield, he devoted himself to eye work and became chief clinical assistant at Moorfields and at the Western Ophthalmic Hospital. He had been a member of the B.M.A. for 34 years.

K. W. M. writes: In the passing of Dr. **Eric Biddle**, as the result of a motor-cycling accident, a humorous, kindly, and benevolent character will be missed from the pathological laboratory of the East Suffolk and Ipswich Hospital. Appointed as the first pathologist to a fine new department, just opened by H.R.H. Princess Mary, Dr. Biddle organized a service which was to expand rapidly during the next few years. So liberal was his nature that in addition to his plentiful work he became curator of radium and penicillin officer. He was among the first who saw the importance of a blood transfusion service, and from small pre-war beginnings he gradually built up a war service which ultimately occupied a considerable part of his spare time. These bleeding sessions were a joy to his co-workers as well as to the donors, all of whom were kept in good humour by his wit and limitless fund of anecdotes. During his 18 years in Ipswich he made many friends by the geniality of his nature. He found company and relaxation in music, founding the Nurses' Music Club, and although not a performer himself it was his pleasure to give many gramophone recitals of classical music. He was a member of the Ipswich Photographic Society, and his skill in this pastime was always at the disposal of his medical colleagues in the preparation of medical data.

A correspondent writes: Those who know the British Legion Village near Maidstone will learn with deep regret of the death of the Matron, Miss **E. Lee**. For over twenty years—since its foundation—she had been the matron and helped the settlement to grow from a small sanatorium of 70 beds to a flourishing village of more than 1,000 people. In the 1914–18 war she did yeoman work for the troops in Salonika. She later worked at Papworth as assistant matron, and it was from there, on the recommendation of Sir Pendrill Varrier-Jones and Miss Borne, that she was chosen as matron at Preston Hall in 1925 when it was taken over by the British Legion as a village settlement.

Medico-Legal

A SOLICITOR AT FAULT

"Ambulance chasing" is the practice of seeking out victims of road accidents and persuading them to agree to an arrangement by which a claim for compensation is made on their behalf and the proceeds divided. The case is usually settled for a deplorably small sum. The solicitor is strictly forbidden to take part in this kind of activity. By his rules of ethics, touting for clients is disgraceful conduct, just as to seek out patients is disgraceful for doctors. He is therefore forbidden to accept a client who has been brought to him by a lay tout. Similarly, he may not associate with any person (or organization, other than a charity) who is beneficially interested in accident claims but is not a solicitor. Before he accepts instructions to proceed with any accident claim he must make reasonable inquiry to see whether in accepting it he will be breaking one of these rules.

A solicitor was recently summoned before the Disciplinary Committee of the Law Society for accepting instructions in nine cases from a member of a body called the "Ex-Regulars Association" without making reasonable inquiry. Some years earlier he had written to the Law Society asking for a "waiver" of the rules—i.e., an exemption which the Law Society has discretion to make in suitable cases—in the case of this body. He explained then that he acted as its "honorary solicitor"; that when a member satisfied the organization that a prima facie case existed which required help the organization issued a letter of introduction to its honorary solicitor and proceedings were started on the member's instructions. The solicitor, he said, received only a retaining fee based on the work done and on disbursements incurred on behalf of its members. The member paid profit costs in accordance with his means as ascertained by the organization. The council of the Law Society had granted a waiver for three years. In September, 1939, being dissatisfied with the solicitor's conduct in a case which he had taken up without any proper authority from the member on the introduction of a representative of the Ex-Regulars Association, the Council withdrew its waiver. In the present case it found he had broken the rules by not making reasonable inquiry, and suspended him from practice for two years. The Court of Appeal upheld its decision.* Lord Justice Scott said that a solicitor owes a positive duty to make reasonable inquiry if he does not know enough to make him substantially certain that there is no risk of mistake. His obligation is greater if he already has reason to suspect that the organization introducing the client is wittingly or unwittingly putting him in danger of breaking the rules. It is greater still if he has already had a warning from the Law Society that his relations with the organization are dangerously near the borderline of professional propriety. The court dismissed his appeal with costs.

The case shows the strictness of the rules governing this kind of practice. There was no suggestion that the association conducted a touting business, still less that the solicitor had any part in persuading the claimants to let him act for them; nevertheless the Law Society imposed a severe penalty. Hospitals who find that "ambulance-chasers" are a nuisance to them by unsettling patients and summoning medical officers as witnesses will find the Law Society very co-operative in counter-measures.

---

*Re A Solicitor (1945) 1 All E.R., 445.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Sir Lionel Ernest Howard Whitby, C.V.O., whose appointment as Regius Professor of Physic was announced last week, was born in 1895 and entered Downing College, Cambridge, in 1918 with a senior open scholarship which he had won in 1914. He also won a scholarship and prizes at the Middlesex Hospital, after serving in the war of 1914–18 as an infantry major and gaining the Military Cross. He graduated in medicine in 1923, proceeded M.D. in 1927, and was elected F.R.C.P. in 1933. He gave the Bradshaw Lecture before the Royal College of Physicians in 1938 and was awarded the John Hunter triennial medal and prize by the Royal College of Surgeons in 1939 for his work in perfecting the drug sulphapyridine while holding the post of bacteriologist at the Middlesex Hospital. During the present war he has been officer in charge of the Army Blood Transfusion Service and consulting physician in blood transfusion to the Army with the rank of brigadier. Prof. Whitby was knighted this year, and in July received the triennial gold medal of the Royal Society of Medicine for his distinguished work on wound shock and the transfusion of blood and blood derivatives.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Faculty held on Sept. 3, the President, Mr. William A. Sewell, in the chair, J. P. Currie, M.D., and M. M. Whittet, M.B., Ch.B., were admitted Fellows of Faculty.

The Services

CASUALTIES IN THE MEDICAL SERVICES

Missing, presumed killed.—Temp. Surg. Lieut. John Murdoch Blyth, R.N.V.R.

Wounded.—War Subs. Capts. J. M. Hamilton, M.C., and P. G. S. Johnson, R.A.M.C.

The September issue of *C.M.S. Outlook*, published by the Church Missionary Society, 6, Salisbury Square, London, E.C.4, contains an article by Dr. Norman S. Macpherson entitled "Vellore: A Venture of Faith," giving an account of recent progress and planning at the medical school and hospital at Vellore, in South India. The Christian Medical Association of India, in consultation with workers on the spot, has decided to develop the existing medical school and hospital at Vellore into an All-India Medical College for men and women, to prepare them for the M.B., B.S. degree of a university.

No. 34

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 25.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Owing to movements of population, birth and death rates for Northern Ireland are still not available.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* infectious diseases were more prevalent. The increases over the preceding week's notifications were: whooping-cough 185, scarlet fever 79, diphtheria 58, and acute pneumonia 43. Those for measles fell by 176, and for dysentery by 27.

The largest of the local rises in whooping-cough were those of Surrey 36, and London 28. Lancashire, with an increase of 41, showed the only big fluctuation in the notifications of scarlet fever. The total for diphtheria was the largest for five weeks; the biggest rises were Yorks West Riding 12, Yorks North Riding 11, Northumberland 11, London 10, Glamorganshire 10. The incidence of paratyphoid and typhoid fevers, with a total of 29 cases, reached the highest level for thirteen months; 13 of the 17 cases of paratyphoid were reported in Lancashire (Barrow-in-Furness C.B. 10).

For the third consecutive week dysentery notifications fell, the largest returns being Essex 33, London 31, Lancashire 19, Middlesex 17, Surrey 17, Lincolnshire 16, Glamorganshire 13, Yorks West Riding 11, Northumberland 10.

In *Scotland* there were small rises in the incidence of most infectious diseases. The largest were scarlet fever 29, pneumonia 27, diphtheria 21.

In *Eire* diphtheria notifications went down by 14, while rises were recorded for measles 16, and whooping-cough 13. Eighty-five cases of infantile diarrhoea were notified in Dublin C.B.

In *Northern Ireland* the totals for diphtheria and scarlet fever fell by half—by 14 and 28, respectively.

Week Ending September 1

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,020, whooping-cough 1,244, diphtheria 377, measles 851, acute pneumonia 265, cerebrospinal fever 33, dysentery 286, paratyphoid 13, typhoid 9, acute poliomyelitis 28.

Medical News

The Central Medical War Committee is informed that the rate of release of medical officers from the Royal Air Force has been accelerated. The following age-and-service groups will be released by the dates shown: By Oct. 31, Groups 13 and 14 (i.e., additional to Groups 11 and 12); by Nov. 30, Groups 15 and 16; by Dec. 31, Groups 17 and 18; by Jan. 31, 1946, Group 19; by Feb. 28, 1946, Group 20.

It has been announced by the War Office that the release of medical officers will be proceeded with up to Group 23 by Jan. 20, 1946, in step with the rest of the Army.

U.S. medical officers from the Continent were among those attending a course arranged at Glasgow University from Sept. 4 to 7 by the Faculty of Medicine and the British Council. The programme included visits to hospitals and the following lectures: "Modern Chemotherapy," by Prof. Carl H. Browning; "Some Features of the Scottish Health Services and their Development," by Sir Alexander Macgregor and Prof. T. Ferguson; "Some Medico-Legal Aspects of General and Specialist Practice," by Prof. J. Glaister; "Tuberculosis in Scotland during the War Years," by Prof. J. W. S. Blacklock; "The Rh Factor," by Prof. D. F. Cappell; "Art and Therapeutics," by T. J. Honeyman, M.B., Ch.B., Director of the Art Gallery and honorary lecturer on the history of painting, University of Glasgow.

The Princess Tsahai Memorial Hospital Council announces an illustrated lecture by Mr. Richard St. Barbe Baker, in aid of the funds of the memorial hospital now being built in Addis Ababa, which it is hoped to complete at the end of December. The lecture, entitled "The Redwoods, Greatest Trees on Earth, and Trees in Relation to Hospitals," will be given on Tuesday, Sept. 25, at 5 p.m. in the Hastings Hall, B.M.A. House, Tavistock Square, W.C., with Mr. W. McAdam Eccles, F.R.C.S., in the chair. Tickets, price 7s. 6d., 5s., and 2s. 6d., may be obtained from Miss E. Sylvia Pankhurst, 3, Charteris Road, Woodford, Essex.

The following meetings are announced by the Royal Sanitary Institute. Sept. 29: 10.45 a.m., at the Southern Secondary School Hall, Fawcett Road, Southsea; papers on "Mass Radiography—A Review of a First Year's Working," by Dr. I. M. McLachlan; and "Aspects of Sanitation in the Navy," by Surg. Capt. E. C. Holtom. Oct. 13: 10 a.m., at Hope Hospital, Eccles Old Road, Salford; papers on "New Remedies in Disinfestation," by Dr. J. L. Burn, and on "The Unfit House," by Dr. J. E. Blease. Oct. 17: 2.30 p.m., at the Institute, 90, Buckingham Palace Road, S.W., paper on "Uses of D.D.T. in the Field," by Lieut.-Col. M. H. Webster, R.A.M.C., illustrated by a sound film.

The Medical Group of the Association for Scientific Photography announces a joint meeting with the Royal Photographic Society, Colour Group and Cinematography Group, to be held in the Hastings Hall, B.M.A. House, Tavistock Square, on Monday, Sept. 24, at 6 p.m. Sergeant Clissna, of the U.S. Army Pictorial Service, will discuss kodachrome cinematography in ward and theatre and show films.

The annual dinner of the Middlesex Hospital Medical School will be held at the Savoy Hotel on Friday, Sept. 28, at 7.30 p m.

Lord Moran, P.R.C.P., will give the inaugural address at the opening of the session 1945-6 of the London (Royal Free Hospital) School of Medicine for Women. The ceremony is to be held in the Great Hall of B.M.A. House, Tavistock Square, W.C., on Friday, Sept. 28, at 3 p.m. Tea will be served afterwards at the Medical School, 8, Hunter Street, Brunswick Square.

The Archbishop of Canterbury will give the inaugural address at the Westminster Hospital Medical School, Horseferry Road, S.W., on Monday, Oct. 1, at 3 p.m.

During the autumn convention in London of the Incorporated Society of Chiropodists on Oct. 4, 5, and 6, there will be lectures by Mr. Norman C. Lake on "Posture: With Particular Relation to the Legs and Feet"; by Mr. T. T. Stamm, on "Disabilities of the Foot Associated with the First Metatarsal"; and by Prof. F. Wood Jones on "The Evolution of the Foot." Particulars may be had from the secretary of the Society, 21, Cavendish Square, W.1.

The following Chadwick Public Lectures will be given in October and November on Tuesdays, at 2.30 p.m. Oct. 2, at Royal Society of Tropical Medicine and Hygiene, 20, Portland Place, W., Mr. A. F. Russell, A.R.I.B.A.: "Planning for New Housing Standards." Oct. 30, at Livingstone Hall, London Missionary Society, 42, Broadway, Westminster, S.W., Dr. Walter P. Kennedy: "Health Education, its Problems and Methods." Nov. 13, at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., Mr. F. C. Vokes on "The Modern System of Sewage Disposal and the Methods and Materials Employed." On Thursday, Nov. 29, at the Westminster Hospital Medical School, Horseferry Road, S.W., Dr. A. M. H. Gray will give the Malcolm Morris Memorial Lecture on "Some Social Aspects of Industrial Dermatitis." Admission to all Chadwick Lectures is free without ticket. Particulars may be had from the secretary, at the offices of the Chadwick Trust, 204, Abbey House, Westminster, S.W.1.

The Food Education Society announces that a public lecture on "Food and Maternal Morbidity and Mortality" will be given by Dame Louise McIlroy at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Monday, Oct. 15, at 2.30 p.m.

A series of lectures on "Human Relationships in the Modern World," arranged by the Provisional Council for Mental Health, is to be given at the Museum and Art Gallery, Bristol, each Friday from Oct. 12 to Dec. 14 inclusive. Among the speakers will be: Dr. W. S. Maclay on "The Study of Human Relationships: its Importance at the Present Time"; Dr. Joyce Partridge, "Men and Women in Partnership"; Dr. Emmanuel Miller, "Parents and Children"; Dr. Frank Bodman, "The Problem of the Homeless Child"; Dr. Tom Garland, "The Individual in Industry"; Dr. J. A. Hadfield, "The Individual in Conflict with Himself"; and Lieut.-Col. R. F. Barbour, R.A.M.C., "Readjustment to Civil Life and Peaceful Living." Tickets (£1 for the course) may be obtained from the offices of the Provisional National Council for Mental Health, 2, Elton House, Rodney Place, Bristol, 8.

The eighth annual Louis Gross Memorial Lecture will be delivered at the Jewish General Hospital, Montreal, on Wednesday, Oct. 17, at 8.30 p.m., by Dr. Paul Dudley White, of Boston. The subject will be, "The Heart in Hypertension since the Days of Richard Bright."

At a course, "Shape of Things to Come," for Canadian servicemen arranged by the British Council, the University of Glasgow, and the Committee for Adult Education in H.M. Forces, held from Aug. 14 to 17, a lecture was given by Dr. A. G. Mearns on "Medicine in the Post-war World."

Quinidine, which is the recognized treatment for cardiac arrhythmias, is almost unobtainable, and in spite of the ending of the war with Japan it is certain that no larger quantity will be available for at least a year. Salts of quinine have been used in the treatment of cardiac arrhythmias, though without notable success. In view of the impossibility of obtaining quinidine, and of the absence of any recognized alternative form of treatment, the Medical Research Council has suggested that cardiologists who wish to do so might give further trial to the use of salts of quinine. The Ministry of Supply has agreed to the use of quinine for this purpose.

The Ministry of Health has informed local authorities of the Minister's decision to extend until March 31, 1947, the period during which the arrangements made by them under the Cancer Act, 1939, should be submitted.

Sir Alexander Fleming, F.R.S., has been decorated with the Insignia of Commander of the Legion of Honour by General de Gaulle.

The International League against Epilepsy, founded in 1935, has continued its activities upon a reduced scale during the war. The United States Branch has been prominent and undertook the responsibility of issuing the journal *Epilepsia*, a commitment which had previously been shouldered by the Danish branch. Under great difficulties the Americans issued a copy of this journal during each one of the war years. It is proposed to resume the annual scientific meetings of the British Branch of this League, and provisionally Friday, Nov. 30, has been set aside for the first of these post-war meetings. Further details will be given at a later date. Any qualified medical practitioner interested in the scientific or social-economic aspects of epilepsy is invited to become a member, and is asked to communicate with the secretary, Surg. Capt. Macdonald Critchley, R.N.V.R., Royal Naval Auxiliary Hospital, Barrow Gurney, Nr. Bristol.

Owing to the war the Government of Iraq has been unable to obtain British professors or British medical specialists, and in consequence a number of chairs at the Royal College of Medicine, Baghdad, are vacant. The College provides a six-years course for some 300 Iraqi students and the teaching is in English. The position has now become acute, and appeals for assistance in filling these important posts have been made to the Central Medical War Committee, which has agreed to help so far as possible in obtaining the personnel required. Applications are invited (see advertisement) from candidates, including any serving in H.M. Forces, with the necessary qualifications, and should be sent to the Overseas Manpower Committee, York House, Kingsway, London, W.C.

A new Order partially removing the restrictions on the use of liver extract has been made by the Secretary of State for Scotland. It permits the use of injectable extract of liver without any restrictions as to the conditions to be treated. It also permits the use of oral preparations of liver (including proteolysed and desiccated liver) on the prescription of a registered medical practitioner for the treatment only of pernicious and other megalocytic anaemias. The Order prohibits the use of any preparation intended for oral administration containing liver extract combined with any other active ingredient except stomach extract.

British civilians who have been disabled by war operations or through enemy detention abroad are entitled to compensation under the Personal Injuries (Civilians) Scheme, and to free treatment for their disablement in E.M.S. hospitals. Notification to this effect has been sent by the Minister of Health to all hospital authorities, in Circular 153/45.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London.*

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Vascular Collapse with Anuria

Q.—*An Indian "other rank" was admitted to a military hospital with acute food poisoning, B. aertrycke being isolated from the massive diarrhoea present. Three pints of isotonic glucose-saline were given intravenously. After ten minutes of running in the third pint the patient shot a hyperpyrexia of 107° with rigors. Subsequently an anuria developed, the treatment being intravenous sodium sulphate followed by intravenous sodium bicarbonate and glucose-saline, with a repetition of sodium sulphate. After six days, during which time a total of five pints of fluid was given and only 30 oz. of urine passed, the patient succumbed. (1) Is there any connexion between the anuria and (a) the original infection, and (b) the hyperpyrexia? (2) What method is recommended for preparing and autoclaving an isotonic solution of sodium bicarbonate?*

A.—A shock-like condition characterized by vascular collapse and anuria may occur in a variety of severe infections and also in hyperpyrexia. It is attributed to pooling of blood in dilated capillaries, with a concomitant reduction in the venous return to the heart and in cardiac output. In the present case the effects of the vascular shock on the kidneys would have been aggravated by the dehydration and disturbances in the blood chemistry induced by the diarrhoea. In such cases oxygen and plasma (1,000 c.cm.) may be of value to maintain the circulation, and they should be used early, for once a patient develops anuria the outlook is very bad under any treatment. There is still much controversy about the nature and total amount of fluid which should be administered to such patients, but bicarbonate should probably not be given parenterally without knowledge of the plasma bicarbonate.

The *British Pharmaceutical Codex* (1934) states that solutions of sodium bicarbonate for injection may be sterilized " by heating in an autoclave, by tyndalization, or by filtration. When the solution is sterilized by heating in an autoclave or by tyndalization, the containers must be airtight and the solution must almost completely fill the container. The containers should not be opened for one or two hours after the temperature of the solution has fallen to normal."

Concentrated Vitamin Dosage

Q.—*In the light of the article by Marion B. Richards in the* Journal *of March 31, 1945, it would seem that by giving a preparation containing, for example, only vitamin* B_1, *nicotinic acid, and riboflavin, to a patient already very undernourished, one runs a risk of antagonizing the action of other factors in the vitamin B complex, about which less is known and which may be of great importance. How far can this possibly be avoided in treating a case such as of severe coeliac disease, where nearly all forms of nourishment are refused and where it is necessary to give the vitamins in concentrated form, or even parenterally?*

A.—So far as is possible vitamins should be supplied by food. When concentrations of vitamins are needed, preparations from natural sources—yeast, liver, or wheat germ—that should contain all the vitamins, should be used when possible. If large doses of an individual vitamin, such as can be given only with pure preparations, are indicated, concentrates should be given, if possible, at the same time. In Richards's experiments the evidence of pyridoxine deficiency did not appear at once; parenteral doses of pure vitamins may be used in emergencies—as nicotinic acid for nutritional diarrhoea—without fear of provoking symptoms of other deficiencies.

Asthma after Pneumonia

Q.—*A patient developed asthma after an attack of pneumonia in 1940. Different localities affect him, and he has now found a district where he keeps relatively free. Unfortunately he finds that the presence of his wife, and also occasionally of other individuals, provokes an attack. There is no marital disharmony, and he himself is well balanced. He has tried sleeping with her hair-brush and with a sprinkling of her face powder on his pillow without result. The psychological element, while a possibility, seems unlikely to me. Could he be allergic to some foreign protein, bacterial or other, in his wife's nose or mouth or dandruff? Skin tests on himself of the usual substances have shown inconclusive results. The seasons make no difference.*

A.—Asthma following pneumonia is usually due to the sufferer's being sensitive to some air-borne inhalant, such as feathers, horsehair, animal hairs, dust, pollens, or orris root, and rarely to any bacteria. The effect of different localities is dependent on the presence or absence of these factors, together with the sufferer's general state of health. His attacks will be more frequent during worries, troubles, mental upsets, or slight ill-health from other causes, depending upon the amount of protective adrenaline he is able to produce himself. Attacks provoked by the presence of another person are usually to do with the person's occupation or connected with the handling of animals. It may be that his wife rides horses or has a favourite cat or dog. This is more probable than that the attacks have anything to do with any foreign protein of a bacterial nature from his wife's nose or mouth. I think that if skin tests were done intradermally with the inhalants mentioned more conclusive results would be obtained.

Oil-in-water and Water-in-oil Emulsions

Q.—*What is the difference between a water-in-oil and an oil-in-water emulsion?*

A.—An emulsion may be described briefly as a preparation composed of two immiscible or almost immiscible liquids, one of which is uniformly distributed in a fine state of subdivision throughout the other. When one liquid is water and the other oil we may have either an oil-in-water (oil/water, O/W) or a water-in-oil (water/oil, W/O) emulsion. In the oil-in-water type the oil is in a fine state of subdivision and is known as being the disperse or discontinuous phase. It is uniformly distributed throughout the water, which is known as the dispersion medium, or external or continuous phase. In a water-in-oil emulsion it is, of course, the water that is in a fine state of subdivision, and it is then known as the disperse phase, and the oil as the dispersion medium. Except with very dilute emulsions a third factor is present, known as the emulgent or emulsifying agent: sometimes also called the intermediate phase, or interphase.

A large variety of substances may be used as emulsifying agents. They are, however, invariably colloidal, and it is the emulgent that usually determines the type of emulsion produced. For example, the gums yield oil-in-water emulsions except when they have in certain cases deteriorated and become acid, when a water-in-oil emulsion may result. Again, the univalent alkalis invariably produce oil-in-water emulsions, whereas the bivalent alkaline earths and trivalent gases invariably give rise to water-in-oil emulsions. The widely used lanette wax SX produces the oil-in-water type.

It is not uncommonly assumed that the proportions of oil and water present determine the type of emulsion, as it is thought that a very high proportion of oil could not be dispersed throughout a very small volume of water. This is, however, a fallacy: it is the emulsifying agent that chiefly determines the type of the emulsion, and, in fact, oil-in-water emulsions containing as much as 99% oil have been produced.

Profuse Periods in Young Girl

Q.—*What is the correct treatment for a girl of 16½ who has profuse periods about every 12 to 14 days, lasting almost a week? There is no dysmenorrhoea and no evidence of organic disease; general health is good. When she started menstruating three years ago the periods occurred at intervals of five weeks, but have gradually got more and more frequent.*

A.—The use of the word " correct " makes this question difficult, if not impossible, to answer. There are many possible lines of treatment for cases of this kind, but none are uniformly successful and most are empirical in nature. In any case there is a natural tendency to spontaneous cure. Thyroid should be tried initially. Begin with 1 gramme daily and gradually increase the dose up to the limit of tolerance. Calcium in large doses can with advantage be given at the same time, and the treatment should be continued regularly for three months. If simple treatment of this kind fails, then try five to seven daily intramuscular injections of 5 mg. progesterone, commencing one or two days before the expected onset of a period. However, in order to be sure of the nature of the underlying disturbance and its appropriate hormone treatment endometrial biopsy may prove necessary.

Tryparsamide for G.P.I.

Q.—*Would you discuss the use of tryparsamide in G.P.I.?*

A.—Tryparsamide is a very useful drug in the treatment of G.P.I., but it should be understood that normally it is used only as a " second string " to artificial fever induced by malaria or physical means. After adequate fever treatment, tryparsamide should be given intravenously in doses of 3 grammes, dissolved in 10 c.cm. distilled water, once weekly for 10 to 12 weeks; this constitutes a " course," which should be repeated, with intervals of a month or thereabouts, over a period of 2 to 3 years or more. It is customary to give bismuth as well as arsenic; the two drugs may be given concurrently or alternatively. The dose of bismuth metal should be about 0.25 gramme per week, and a rest interval should be given when the total reaches 2.5 grammes. Tryparsamide is liable to cause amblyopia, and the patient's eyes should be examined by an ophthalmologist before arsenical therapy is initiated, and again after a few injections, in order to obviate this; if the eyes are not affected by the first five injections or so they are unlikely to be affected later.

Tryparsamide is supplied in powder form and should be dissolved immediately before use, though it has not the same tendency to become toxic on exposure to the air that neoarsphenamine has; apart from its effect on the eyes it rarely causes serious toxic reactions.

Stilboestrol for Premature Infants

Q.—*What is the rationale of administering stilboestrol (or other hormone) to premature infants? In what dosage is it given to such babies?*

A.—During pregnancy large amounts of oestrogen are present in the maternal circulation and pass through the placenta to the foetus. This is excreted from the foetus within two or three days of birth, so a baby born before term is prematurely deprived of its influence. There is nothing to show that the action of oestrogen on the baby *in utero* is specially beneficial, but, on the assumption that it is, it has been administered to babies born prematurely. Synthetic oestrogens such as stilboestrol are too powerful and toxic for this purpose, and the natural oestrogens are to be preferred. The usual dose is about 500 i.u. (0.05 mg.) in a little warm water, twice daily by mouth. For details see Mabel Potter, *Journal*, 1937, **1**, 1201.

Poisonous Fish

Q.—*My boy, while shrimping, was stung by a fish (probably a weever fish) he had caught in his net. Almost immediately his finger became very painful, red, and swollen. Shortly afterwards the swelling extended to the back of the hand. Treatment was on general lines, and the condition is settling. What stinging fish are likely to be met with round our shores? What is the nature of the poison of the weever fish, and what is the appropriate treatment?*

A.—There are two species of weever fish which frequent the coasts of Britain: the greater weever (*Trachinus draco*) and the lesser weever

(*Trachinus vipera*). The greater weever, though provided with a poison apparatus, does not cause many casualties, as it lives in fairly deep waters away from the shore; whereas the lesser weever inhabits the shallow waters near the shore, with the result that children and shrimpers are often stung. The stinging apparatus of the weever is contained in the spines of the anterior dorsal fin and also in the large spines which form a continuation of the gill covers. The glands which secrete the poison are lined with columnar epithelium and discharge the poison down grooves in the spines. The sting causes acute pain and local inflammation. Weever venom causes haemolysis and reduces the opsonic index of the leucocytes. This latter phenomenon is no doubt the reason for the inflammation which nearly always follows a sting from one of these fish. Other poisonous fish inhabiting our coasts are the spiny dogfish (*Squalus acanthias*) and the sting ray (*Trygon pastinaca*). Further information on stinging fish can be found in *Sting-fish and Seafarer*, by H. Muir Evans (Faber and Faber Ltd., 1943).

For immediate treatment an injection of a few minims of 5% solution of potassium permanganate at the point of entry of the sting is recommended. For the subsequent inflammation treatment should be on the usual general lines.

Sodium Amytal

Q.—*An intelligent middle-aged man, an active brain-worker, who is of an anxious worrying temperament and of the unstable vasomotor type, finds that life is made more comfortable and tolerable for him if he takes 1 grain of sodium amytal night and morning. He shows no sign of idosyncrasy to the drug and is perfectly fit otherwise. Apart from damage to his personality which would result from a feeling of dependence on any drug, what are the physical risks entailed in allowing him to continue this habit more or less indefinitely, and is there any risk of intellectual deterioration?*

A.—Experience of prolonged use of sodium amytal over years is still very small; but the drug seems to be very non-toxic, and in a small dose such as 1 grain twice daily there should be no physical risk whatever. Almost certainly it would have less undesirable effect than one small whisky night and morning. There is no risk of intellectual deterioration. Experience to date suggests that the risk of addiction—i.e., of requiring increasing doses to secure the same effect—is also minimal.

Fractured Femur in Child

Q.—*A child of 5 years has a fracture of the lower third of the right femur, not into the joint. There is good union, and anatomical position is good. Treated in gallows splint for six weeks. Must the child wear a walking calliper and, if so, for how long?*

A.—A gallows splint is not usually regarded as a good method for children of that age—the Thomas leg splint is much better. In this particular case I should advise the questioner to get the child up and about with crutches for a couple of weeks at least before allowing weight-bearing on the affected limb.

Bruising and Rheumatism

Q.—*Is the occurrence of spontaneous "bruising" of the skin a recognized feature of the rheumatic diathesis? The patient in question is a woman of 50, in good health apart from rheumatic pains, which she has had for the past 25 years, and a commencing mild atrophic arthritis of wrists and knees.*

A.—Anaphylactoid purpura may present bruising due to effusion of plasma from the blood vessels with a varying amount of cells, and a similar effusion may occur into the joints, giving rise to pain and swelling regarded as rheumatic. It would thus be more accurate to speak of a haemorrhagic diathesis with rheumatic symptoms than a rheumatic diathesis with spontaneous bruising as a feature. Lichtwitz, however, regards rheumatic fever as an allergic reaction, and erythema, urticaria, and purpura as skin lesions due to the small allergic reaction. In the case in question it would be desirable to have a complete blood examination, including the sedimentation rate as an indication of a possible infective focus; if the rate is not increased then the arthritis is presumably not of the rheumatoid type. The blood tests should include the clotting time, a count of the blood platelets, and the vitamin C content. As the condition has existed for 25 years, apparently without any ill effect on the general health, treatment does not appear to be urgently needed, and the more radical methods such as blood transfusion would not be justified. Injection of horse serum is often effective for a time.

The level of vitamin C in the blood is usually lowered in rheumatic diseases, and if this is found to be the case the administration of ascorbic acid is worth a trial; it may prove beneficial even if it does not directly affect the bruising tendency. Authorities differ on the question whether ascorbic acid is alone effective, and vitamin P is held by some to be the active agent, improving capillary resistance; it is present with vitamin C in lemon juice. If, on the other hand, there is a prolongation of the clotting time, the deficiency is probably in vitamin K, present in many green vegetables, tomatoes, soya bean, etc. Lowered capillary resistance is, however, the most probable cause in this case, and a substantial increase in the intake of vitamin-C-containing fruits and foods may be of general benefit and can do no harm. If the sedimentation rate is increased and the diagnosis of rheumatoid arthritis is thus confirmed, great caution will be desirable in the use of gold as a method of treatment.

Fear of Heights

Q.—*A patient very interested in architecture has an incomprehensible feeling of terror when he finds himself in any lofty building like a cathedral. I suspect that only psycho-analysis will discover the cause of this fear, but is there any general theory which would indicate possible causes?*

A.—A variety of causes, or contributing factors, is given for the fear of heights. It is said, for instance, that astigmatism, with its lack of visual co-ordination, plays an important part. Others find the cause to be a confusion of mental association, the sensation from the feet indicating that one is 6 feet from the ground, whereas the eyes indicate that one is 60 feet from the ground, which leads to a tendency to giddiness with a corresponding fear of falling. This does not occur in an airplane, because then most of the body is in contact with the seat, which is the prevailing factor, and the earth below is simply a distant view.

Biologically the fear of falling is an innate fear (Watson regarding it, and the fear of noise, as the *only* innate fears). It starts at birth and is possibly derived from our arboreal ancestry, with its danger of falling from trees. This naturally passes away; but if it is reinforced by an experience of falling in childhood one may become over-sensitive to this stimulus, and a later fall or threat of a fall may precipitate it into a conditioned fear. This is rarely a sole cause. More commonly the fear is symbolic. There may have been a primitive fear of falling, but this is transferred to a moral situation; so the fear of falling may come to represent a subconscious fear of a moral lapse (we talk of "fallen women"). Most commonly, in our experience, it is found in those who have a "power psychology," who are ambitious, who crave for power and achievement, to reach the heights. If we aim too high and live on a pedestal we have reason to fear falling from our heights of attainment, and the fear may take a physical form. In other cases it goes a step further, and occurs in people who, in their efforts to achieve, become overstrained, and therefore want to "let everything go" in passive abandon; this wish, taking a physical form, is then feared. Or it may, with less likelihood, be a sexual masochism: like the lady who had the desire to be "less than the dust beneath thy chariot wheel"! It is probably true that only analysis (not necessarily psycho-analysis, which applies only to the Freudian method) will discover and eradicate the cause. The true cause may be found in a combination of some of the factors mentioned: an actual fall in infancy produces a fear of heights; a reaction to this fear takes the form of assertiveness and self-sufficiency to overcome the fear, this overcompensation of power being a mechanism to keep the fear at bay; the fear of failure in attaining one's ambition of power then takes a symbolic form, and the desire to let everything go increases the fear. In the final resort the fear is therefore a fear of a wish, like most phobias.

Schick Test and A.P.T.

Q.—*In the* JOURNAL *of May 8, 1943 (p. 589), under the heading "Duration of Diphtheria Prophylaxis," it is stated that a reinforcing dose of A.P.T. should be given from 3 to 5 years after the first immunization against diphtheria. A note on Aug. 4, 1945 (p. 171) states that the boosting dose should not be given in "children of 7 and 9 years" without preliminary Schick tests; it is not clear whether this applies only to asthmatic children. Is Schick testing necessary before giving a reinforcing dose of A.P.T. in all children over 6 years of age, and unnecessary under that age?*

A.—If children are inoculated with diphtheria prophylactic at the age of 1 year or earlier, the artificial immunity thus induced may wane within the following 2 to 3 years, particularly if the child is not much exposed to "natural stimuli" from contact with other children who may be diphtheria carriers. Thus young children have been found to have very low levels of diphtheria antitoxin in their blood 2 to 3 years after the primary inoculations, and have developed diphtheria, usually of a modified type. When these children go to school they are more likely to receive natural stimuli to antibody formation from contact with cases of diphtheria and diphtheria carriers, although with high rates of immunization among school-children such stimuli will be less common in future. It is at this stage, when the child is partially immunized, that pseudo-reactions with the Schick test tend to occur, and pseudo-reactors are most liable to severe reactions after an injection of diphtheria prophylactic. While, therefore, there is little likelihood of untoward reactions to a boosting dose given to a child aged 3 to 5 years in whom the antibody titre has probably dropped to a low level, the chances of such a reaction are greater with older children at school. Obviously no precise age limit can be given at which it is safe to give the boosting dose without a preliminary Schick or Moloney test, since environmental conditions may affect the child's antibody response. A good guide might be to Schick-test all children who had been at school for a year or more, before giving a further dose of A.P.T.; or, alternatively, to use T.A.F., a less potent antigen, for the boosting dose in such children.

Housemaid-Receptionist and Unemployment Insurance

Q.—*An inspector of the Ministry of National Insurance called upon me and inquired about employees of myself or by the partnership. The surgery accommodation is at my house, and I employ one maid. She helps my wife with the work of the house, and, of course, answers door-bells, telephone, and so on. The inspector claims that the maid is employed as a receptionist and as such should have a card stamped weekly for unemployment benefit as well as N.H.I. benefit, and has requested a payment of £10-odd for arrears. This seems to me to be a new departure and one not lightly to be acceded to, and I should be glad of your comments and advice.*

A.—The question is whether the maid's employment as a receptionist is substantial or merely occasional. There are no hard-and-fast rules; each case has to be decided on its own facts. The doctor or the maid, or both, may appeal to the Minister, applying on the appropriate form, which can be obtained from the local office. The Minister will probably appoint a barrister or a solicitor to conduct a local hearing and report. An appeal against his decision can be brought to the High Court.

INCOME TAX

Indian Army Personnel

"I.A.M.C." asks (*a*) whether an officer in the Indian Army Medical Corps proceeding to the United Kingdom for permanent residence there will be liable to United Kingdom tax on allotments paid in this country in the income-tax year of his return if he maintains a residence here prior to return, and (*b*) what is the position as regards I.A.M.C. officers returning to their homes in Britain for 28 days' leave or longer.

⁂ (*a*) Yes, he is liable for the year of return on pay or allotments issued here. (*b*) Such officers are apparently liable in respect of their pay for the period spent in this country—assuming they are maintaining a residence here. *General Note:* As the liability turns on "residence" in this country, the normal personal and family allowances can be claimed on the full year's basis. Further, if tax is paid in both countries in respect of the same income, relief from the double income tax can be claimed.

Wife's Salary as Dispenser

D. W. pays his wife £104 per annum as dispenser. Payment is made quarterly. How should tax be paid on the salary?

⁂ Presumably the wife is an employee and her salary is charged against the profits of the practice. The payments made to her are "emoluments" falling within the P.A.Y.E. system, and tax should be deducted therefrom accordingly.

Liability on War Loan Interest

A. L. has had an income of £180 from war loans since 1941, when it was declared for income-tax purposes. He has now received a demand note for the tax on this interest for 1942–3 and 1943–4, though during those years it was entirely spent on university and college fees.

⁂ The tax is legally assessable. The liability is not affected by the purpose for which the income was expended.

Deduction for Use of Car

"INQUIRER" asks what deduction can be claimed for the use of a car required for transport to clinics and hospitals. What is the position if a mileage allowance is given by the employer?

⁂ A deduction can be claimed for the amount of the expenses incurred "wholly, exclusively, and necessarily" in travelling between the places where the duties of the office held have to be performed. No rule can be given of general application as to what that amount would be—it clearly depends on the circumstances of each case. If a mileage allowance is received no further claim can usually be made, as it is prima facie deemed adequate for the "necessary" expenditure, but of course it is not regarded as part of the chargeable earnings.

Tax Payable on Pension

A. B. inquires what tax would be payable on a pension of £512; he is married and has a niece, aged 17 years, for whom he is entirely responsible, though she is not legally adopted.

⁂ Unless the niece is receiving whole-time education of a recognized form no allowance for her is claimable. If she is receiving such education and no other individual is entitled to an allowance in respect of her the amounts of tax shown below as payable would be reduced by £25. The tax payable on the pension calculated as for the present financial year is £136 12s. 6d., of which £37 will ultimately be returnable as "post-war credit." It is of course possible that the tax for the year commencing April 5, 1946, may be the net amount—i.e., £111 13s. 6d. or less—but that depends on future legislation.

Sale of Car

"MEMBER" asks: If a car, used for professional purposes, on which depreciation has been allowed annually, is sold for more than the difference between the aggregate of the amounts allowed for depreciation and its original cost, is the excess subject to income tax or would any adjustment of past depreciation allowances be made?

⁂ The excess is not subject to income tax—the car being part of the professional equipment and not stock in trade—and no adjustment is due in respect of past allowances, which were presumably reasonable on the facts as then existing.

LETTERS, NOTES, ETC.

Sting-ray Poison

Dr. W. H. PALMER (Hayle, Cornwall) writes: Having just read Dr. R. H. Blair's letter (Aug. 25, p. 267) and Dr. Muir Evans's letter referred to (which I had previously missed), I am wondering if the sting-ray poison is analogous to that injected from the dorsal spine (with poison sac at its base) of a little transparent fish (I don't know its name) that hides in the sands here in shallow water, in such a way that the sole of the bather's foot can be punctured and receive the poison, giving intense pain and cramp all up that leg, with varying degree of shock, nausea, and malaise, but very little local signs of puncture. In these cases I find that subdermal injections of (1) 10 minims of adrenaline 1 in 1,000 repeated if found necessary, (2) calcium and vitamin D 2 or 3 c.cm.—put into different areas of the poisoned limb—give fairly quick relief. The idea came to me when wondering if the poison was allergic in nature. Anyway, whether that is so or not, this treatment seems to act well, and might be worth trying in cases of sting-ray and jelly-fish poisoning.

A Fatal Shot

Dr. ERIC GARDNER (Weybridge) writes: A man using a borrowed 12-bore shotgun in a harvest field, and standing at the top of the field, which was on a very steep slope, had just reloaded, and as he closed the breech the right barrel, the lock of which was defective, discharged. A farm hand standing 36 yards away at the bottom of the slope and looking upwards towards the gun received the full charge in front. He fell down and died almost immediately. The necropsy showed that 47 pellets had struck his chest, abdomen, and upper thighs, with a few scattered shot-holes on his arms and lower face, but only two of these pellets had even penetrated the skin and had done no harm. The brain was covered with a very large subarachnoid haemorrhage spreading up the sylvian fissures on to the surface of the hemispheres, with a good deal of subdural haemorrhage as well. The right posterior cerebral artery was severed, and between the cut ends a No. 5 pellet was lying. Of the 48 pellets that struck the body one only was responsible for death, and that one had entered the right nostril, passed through the sphenoid sinus just to the right of the middle line, emerged through its roof, and travelling backwards, had severed the right posterior cerebral artery.

Sensitivity

Major W. O. G. TAYLOR, R.A.M.C., writes: We have to thank Dr. A. C. Lendrum (Aug. 11, p. 198) for his remarks. Of course it is known that sensitiveness may occur to any substance under the sun—even to sunlight itself. So it has to be expected that cases or sensitiveness to the plasticizer of sensitive resin may quite well occur, and this should be borne in mind when reading the answer in the column "Any Questions?" on the effectiveness of phthalates (Aug. 18, p. 240).

Disclaimer

Dr. SIDNEY E. CROSKERY (Tunbridge Wells) writes: My attention has been drawn to the mention of my name as the doctor attending a premature baby in an article in the *Kent and Sussex Courier* of Sept. 7. This notice was put in without either my knowledge or consent.

Corrigenda

Dr. F. J. WILFRID SASS writes: In my letter "Tuberculous Persons in Prisons" which you kindly published on Sept. 1 I made two omissions: in the seventh line from the bottom of the page, after the words "on a mattress," "in the open air" should have been written; and in the last line of the letter I should have said "(greens, peas, carrots, parsnips, turnips, and onions were often served)."

In the *Journal* of Sept. 8 (p. 341) appears a question and answer under the heading, "Sex Hormones to Control Uterine Bleeding." In the last sentence of the reply the word "stimulate" should have read "simulate."

BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 22 1945

B.L.A. SURGERY

BY

Brigadier A. E. PORRITT, C.B.E., F.R.C.S.
Consulting Surgeon, 21 Army Group

Brigadier R. K. DEBENHAM, O.B.E., F.R.C.S.
Consulting Surgeon, Second (British) Army

AND

Colonel C. C. ROSS, F.R.C.S.Ed.
Consulting Surgeon, First (Canadian) Army

Just eleven months of war surgery—from the tents and grubby outbuildings of the semi-demolished villas and farmhouses of the Normandy coast to the modern, well-equipped German hospitals of the Baltic coast. But what a fascinating series of surgical as well as tactical situations those eleven months produced! For let it be said at the outset that the closer the links between the clinical and administrative sides of a medical organization, the better the results. And the more the administrators keep the clinicians in the tactical picture, the more intelligent and productive becomes the co-operation. Such a happy state of affairs existed and persisted throughout the whole of this campaign; and when to this stimulating atmosphere are added excellent equipment, what can only be called lavish supplies, extremely well organized evacuation, a first-class transfusion and resuscitation service, and a group of young surgeons whose surgical efficiency and clinical common sense were equalled only by their loyalty to a common cause and a common policy, and whose patients were drawn from armies superbly led, with morale and health at their highest pitch, well equipped, well clothed, and well fed—it will be seen that N.W. Europe was indeed the war surgeon's paradise.

Results

To give some idea of what B.L.A. surgeons achieved in the time the following figures are quoted. Realizing that figures are essentially fallacious, we give them only approximately. During the campaign there were 406,000 admissions to medical wards; of these, 258,000 (64%) were treated in the theatre and 148,000 (36%) evacuated to the United Kingdom. Of these evacuations it is worthy of note that over 50% were by air. Of the total admissions 181,700 (45%) were battle casualties. Of these, more than 50,000 received their surgical treatment in forward areas (approximately 28%), two-thirds of this group being serious major wounds. Of the total battle casualties, 39% were evacuated to the U.K., 61% were treated in B.L.A., and only 6.7% died of wounds. One other interesting comparison may be made between this campaign and the last war. In the latter, 41 of every 1,000 troops became a casualty each month (i.e., killed, missing, prisoner, wounded, or died of wounds); in this theatre only 21. It will of course be realized that a surgeon's work in the Army extends considerably beyond the limits of battle casualties alone—accidents and "ordinary" surgical conditions accounting for a very large number of cases. There can be little question, therefore, of the quantity of work done by our 170-odd surgeons; of the quality, an overall recovery rate in an active theatre of war of approximately 94% seems to speak for itself.

History

Let us now briefly follow this campaign through its salient phases and observe the varying effects of different tactical situations on surgical organization and policy. Some 30 surgeons actually took part in the epic of D Day—surgeons of the forward units (C.C.S.s and F.S.U.s) which landed immediately behind the invading troops. Their adventures were legion and stirring, their work as arduous as it was excellent. In any building affording a minimum of cover to the cacophonous accompaniment of shells, bombs, mine explosions, artillery and anti-aircraft fire they worked steadily, fulfilling by rapid but careful selection of cases as important a function as they did by their excellent surgical technique. For even when tents could be erected the holding capacity of the beach-head—and for those first weeks a very thin beach-head it was, especially on the left flank by the River Orne—was minimal. Every case that had a reasonable chance of reaching the U.K. alive was evacuated, chiefly by the ubiquitous "ducks" to specially fitted L.S.T.s, and later by air. This amphibious evacuation proved up to the hilt the enormous value of the pre-D-Day practice landings when we got to know, and on the actual beaches to appreciate, the full and cheerful co-operation of the Royal Naval Medical Service—and, at that time, particularly of Surg. Capt. Miller. And yet in that first month of June, 1944, out of 21,000 surgical casualties, nearly 1,200 were operated on in Normandy. Five hundred of these were abdominal wounds, 130 chest wounds, 200 amputations, 150 compound fractured femurs, 60 penetrating knee-joint wounds, and 50 gas gangrenes. Under the conditions existing, that 80% of the 1,200 should have survived is a tribute to the surgical pioneers of B.L.A. Incidentally, they held and saved 70% of their 500 abdominal cases. At this stage it is fitting that we should remember the air-borne surgeons who dropped on D Day on the far bank of the Orne. Their results are included in the above excellent figures. And then gradually—very gradually—the beach-head became a bridgehead. Fighting was intense and continuous. The weather was hot, but there were few days without showers. Either mud or dust was always with us; the few roads, all the lanes, and most of the fields were full of transport; enemy air activity persisted at night, but most casualties were due to mines, mortars, and artillery.

In the midst of all this a medical organization soon took shape. The remains of the original beach units became evacuation centres; a line of small hospitals, their surgical potential boosted up by the addition of F.S.U.s, were established a few miles inland, and ahead of this the C.C.S.s and their attached F.S.U.s bore the main brunt of the surgery. These "surgical centres" consisted usually of two C.C.S.s lying together and working alternately—to each of which were attached 2 F.S.U.s and an F.T.U.—the whole being screened by an F.D.S. filtering off sick, exhaustion cases, and minor wounded. Such a set-up in the restricted confines of the bridgehead worked admirably and smoothly. Lines of evacuation were short and cases were dealt with relatively soon after wounding. At this period several other events of importance were taking place. Nursing officers started to arrive from D + 8 onwards, resulting in an immediate and obvious improvement in post-operative care. No words of praise can be too high for these sisters, who at that stage and throughout the campaign, often under the most uncomfortable and unpleasant conditions, cheerfully and efficiently carried out their excellent work. In the midst of the Second (British) Army, the First (Canadian) Army began to take shape, and their various medical units were fitted into the scheme of things to come. At the same time more and more general hospitals were filtered in and set up under canvas in the pleasant orchards of Bayeux—so that limited holding of cases became possible. In these hospitals—and during that period they were nothing but glorified C.C.S.s—the will to work was enormous, and is well exemplified by our lady physiotherapeutists, who, having no physiotherapy to practise, toiled long gruelling twelve-hour shifts to prove themselves first-class and invaluable receptionists.

Such was the picture for the first eight weeks—a gradually increasing orderly congestion which steadily reached bursting-point in early August. Meanwhile the battles of the Odon, of Caen, of Caumont and the woody Bocage country, and of the Orne, had been grimly fought and won. And so to the American break-out on the right flank, which wheeled left, advancing south and east. Much of the German Army was trapped in the resulting pocket; the rest poured out through the now famous "Falaise Gap," there to be decimated by Allied air forces. The carnage of men and animals, the litter of wrecked vehicles of every description, the masses of discarded equipment and arms, are sights which will never be forgotten by those who saw them. Then started the first "motoring war"—a rapid advance from Normandy into Belgium from Aug. 12 to Sept. 3. The Second Army pushed on steadily and rapidly across the Seine to Beauvais, Amiens, Lille, Brussels, and Antwerp. The Canadian Army's advance up the coast was more chequered by the "fortresses" of Havre, Boulogne and Calais, Dunkirk—which held out beleaguered to the end—and Ostend. Casualties were relatively light—morale was at its highest. Scenes of the greatest enthusiasm accompanied the advance, culminating in the tumultuous welcome given by Brussels on its liberation. The underground movement of both France and Belgium gave invaluable help during this period, harassing the retreating enemy, capturing and holding strategic bridges and buildings, clearing up residual enemy pockets, and giving information about mines and booby-traps. So precipitate was the advance that little trouble was given by these devices. Prisoners poured in—many of them wounded—and for the first time we took over and used German military hospitals. This was the beginning of the transition from tents to buildings. At that time we had not got used to the filthy condition in which the Germans left their evacuated hospitals—nor had we become acclimatized to the pitifully low standard of German war surgery. Chronic sepsis and toxaemia everywhere; pale, drawn patients and the all-pervading smell of pus; major joints drained; dozens, hundreds of empyemata; wounds sewn up, guillotine amputations, brain fungi, metallic fixation of compound fractures, heavy uncomfortable plasters, bed-sores galore—such was the German war surgery of 1944–5, for later in Belgium, in Holland, and in Germany itself we found the same sad state of affairs.

One surgical point of interest in the 300-mile advance was the different use of forward units made by the two armies. The Second Army kept its C.C.S.s "leap-frogging" one another; the Canadians used advance surgical centres (field dressing stations with attached field surgical units). Both in fact were eminently satisfactory. We feel that the principle of segregating forward surgery to C.C.S.s is still the right one in that conditions and facilities existing at this level are so much more suitable for both patient and surgeon; but there is no doubt that in a rapid advance the advanced surgical centre has a definite and valuable place. In this phase air evacuation really came into its own, and without it evacuation of casualties back over the war-scarred congested roads to Normandy would have been virtually impossible. As it was, the R.A.F., with the able guidance of Air Commodore Murphy and Group Capt. Bruce Harvey, appeared with a Dakota and almost magical regularity on what seemed quite impossible fields almost alongside C.C.S.s and surgical centres. We, as surgeons, then and on many subsequent occasions had every reason to be grateful to the R.A.F.—both its medical service and its air crews—for their whole-hearted co-operation.

Automatically the enormously stretched line of communication slowed up the advance, and in the pause a medical centre of forward units was established in the muddy fields of Diest (40 miles east of Brussels), a 600-bed hospital by herculean efforts was brought up from Bayeux and established in a luxurious Brussels hospital, and the Canadian units in Belgium increased rapidly. But air evacuation became a vital necessity, and it was provided either direct from Brussels to the U.K. or down the coast to Normandy.

Once again for a short period of two to three weeks the evacuation problems were almost those of D Day over again. During this period the lively battles—the recuperative power of the German Army then was extraordinary—of the Albert and Escaut Canals were fought and won and the way paved for the Second Army's dramatic drive through Eindhoven to Nijmegen and on towards, but sadly not to, Arnhem. The part of the air-borne troops, both American and British, in this operation is too well known to require comment. And so was established the "Nijmegen corridor," a narrow hazardous projection, several times cut by German troops escaping eastwards, which needed three months' solid fighting before it was sufficiently expanded to allow a further major advance, and at the top of which from the very beginning were two C.C.S.s whose work was a surgical epic in itself. There cannot have been many occasions when a C.C.S. actually formed part of an attacking column!

During those same three months of hard gruelling fighting the Canadians cleared the coast north of Ostend and the bloody pocket of the south Scheldt, they won through the toughest of all small amphibious operations—the taking of Walcheren—and they lined the south bank of the Meuse up to the corridor. So was the great port of Antwerp really freed to perform its vital function in the campaign, only to find itself almost immediately the chief target of Hitler's newest devilish device—the "V" bomb. Meanwhile to the east and the west the corridor was broadened, and such now famous places as s'Hertogenbosch and Tilburg, Venlo, Venray, and Sittard slowly fell; the line was firm up to the Meuse right down to our junction with the American Ninth Army at Maastricht. Many times we worked with our American colleagues—either alongside or actually under the same command—a symbiosis which was always as happy as it was fruitful. So also were our frequent meetings with Col. E. Cutler, the Chief Surgical Consultant of E.T.O.U.S.A.

These dour battles over the waterlogged flats of northern Belgium and south-east Holland produced a steady flow of casualties—chiefly from mortar fire and from the ubiquitous mine-fields. Forward surgical units were always in the van; evacuation was good, by air and by train; and a large and efficient organization of hospitals, transplanted from Normandy, became established in Belgium and northern France to deal with all except the long-term casualties.

And so to the brief hectic interlude of Rundstedt's break-through in the Ardennes and those weeks of heavy snow and freezing cold and bitter defensive fighting once again. The almost entire absence of "trench feet" during this time was a point of noticeable interest, as was the increased difficulty in resuscitating wounded previously exposed to the rigours of the weather.

Then a mounting crescendo of activity—tempered by a rapid thaw and the consequently appalling condition of the roads—until on Feb. 8, 1945, the First Canadian Army, heavily reinforced with units of the Second Army, began their brilliant drive down from Nijmegen through the mine-strewn heavily fortified (Siegfried Line) Reichwald Forest to clear the territory between the Meuse and the Rhine: fighting in Germany—a devastated belt as the result of previous R.A.F. bombings—and fighting as bitter as any since D Day. Large concentrations of forward surgical units at Nijmegen and Venray had a hectic time. One C.C.S. alone dealt with 5,000 cases in three weeks. But the result was achieved early in March, and we sat on the banks of the Rhine. A short period of regrouping and then the triumphant crossing of the Rhine on March 23, 1945, accompanied by its "biggest-yet" airborne landing—a "crossing so beautifully planned strategically that the resulting casualties were surprisingly and unexpectedly light."

And so to the "Second Motoring War"—a streaming out over the Westphalian plain north and east against weakening opposition; short pauses for determined isolated pockets of resistance and at the major rivers—the Weser and the Elbe; a relatively easy capture of Bremen and a simultaneous surrender of Hamburg and arrival on the Baltic coast—and the final surrender in the first week of May. Meanwhile the Canadians had crossed the Rhine, below the famous Arnhem, and pushed on to the North Sea, thereby cutting off the entire German armies in Holland. They rapidly advanced north to take part in the Battle of Bremen and so share the concluding victory.

All this last stage saw steady but relatively small casualty lists—being dealt with by the rapidly leap-frogging C.C.S.s and small hospitals, and with advanced surgical centres again in the limelight. Problems greater than surgical casualties soon emerged: masses of German prisoners, both wounded and unwounded, numbers of displaced persons of every conceivable nationality wandering in every direction in various stages of disease and starvation, and the ghastly horrors of Belsen, Sandbostel, and other smaller concentration camps. Even before hostilities ceased three large general hospitals had been moved into Germany to assist in dealing with these problems and to speed the last of our battle casualties on their way.

Units

It is not our intention to deal in any detail with the various surgical units involved in this stirring picture, but simply to stress some salient points that seem of importance. It was a great pleasure to us to note the increasing interest of divisional units (field ambulances and field dressing stations) in surgical policy. We firmly believe that the correct initiation of sound first aid and judicious but limited resuscitation at this level is of vital importance in the subsequent success of surgical treatment proper. Every possible effort was made by Army Surgical Consultants to contact and to advise forward medical officers.

The C.C.S., practically always with attached field surgical units, has borne the brunt of the serious forward surgery. As at present constituted, it is rather too small, but in any planned action two C.C.S.s were brigaded together and screened by a F.D.S., which took off lightly wounded, sick, and exhaustion cases. Such an arrangement worked admirably, the two C.C.S.s functioning in rotation according either to the number of admissions or, more frequently, to the number of cases awaiting operation. It was of interest to note that a steady 15 to 20% required operation at this level. To all such set-ups one or more of those invaluable little units—the field transfusion units—were added, and were responsible not only for the resuscitation of operative cases but also very largely for the choice of priority in operation and for assistance in post-operative care. Each C.C.S. carried 8 to 10 nursing officers, whose work, as already mentioned, was beyond praise. The type of case dealt with at this level became quite stereotyped: haemorrhages; severe multiple wounds; traumatic amputations; abdominal, thoracic, and abdomino-thoracic wounds; severe compound fractures, especially femurs; and suprapubic drainage for paraplegias. Of such cases the average surgeon could do approximately 15 in his tour of duty. This we found was optimum at "12 hours on and 12 hours off." The latter period included ward visits as well as rest.

The siting of C.C.S.s of armies varied with the tactical situation from 2 miles behind the "line" to 80 miles, but the vital time interval between wounding and surgical care remained at a remarkably steady average of just under 12 hours in all conditions. We believe firmly that the right place for forward surgical treatment—from the patient's, the surgeon's, and the nurse's points of view—is just out of enemy artillery fire and behind our own big guns. This ideal was by no means always achieved.

The advanced surgical centre (F.D.S. and F.S.U.s), as has been already pointed out, was used on many occasions, but as a surgical entity it is definitely "second best" to the C.C.S. Its value in a rapid advance of a very mobile type of warfare has become more and more appreciated, not only by medical administrators but also by combatant generals.

The 200-bed general hospital was in this campaign used as a glorified C.C.S.—and as such fulfilled a most valuable role. To allow this, surgical potential had to be boosted by the addition of F.S.U.s. We feel that this unit would be better employed in producing slightly larger C.C.S.s and that its intended semi-static functions might well be carried out by an F.D.S. On the other hand, the inclusion of a 1,000-bed convalescent depot in Army areas was of inestimable value in saving man-power and in ensuring rapid rehabilitation.

A word about the special neurosurgical and maxillo-facial teams. We officially had one each of these per army and we had one thoracic team per Army Group. In fact, by incorporating specialists in ordinary hospital establishments we possessed extra neurosurgical and thoracic teams. But compare this with the Americans' 12 to 15 neurosurgeons and 7 to 8 maxillo-facial surgeons per army! However, the work done by these few special teams was relatively as great in quantity as it was excellent in quality. The value of adding an otologist to maxillo-facial teams was amply proved. The advantage of the neurosurgical and maxillo-facial teams working close together, and with an ophthalmologist readily available, was already known—and the policy was adhered to. Luckily, the cases treated by these two teams do not require urgent operation; after preliminary first-aid surgery and the provision of chemotherapeutic prophylaxis they can safely await definitive operation for several days if necessary, without undue risk; and they travel well.

Hence in the Normandy days many cases were sent to the U.K. for definitive treatment; in the Belgian period the teams remained in Brussels and Antwerp almost until the Rhine crossing—air evacuation providing their pabulum in good shape and relatively quickly. Nevertheless, to cope with the urgent "special case," and more particularly with the special wound combined with another wound requiring immediate surgery, we felt that further "special" cover was necessary, and this was provided by training a proportion of F.S.U. surgeons in elementary maxillo-facial and neurosurgical work and by giving them minimal special equipment—a policy which in the latter part of the campaign paid good dividends. There is no doubt, too, that the base areas of any theatre of war require cover in these specialties as well as the armies.

The work of the thoracic teams was limited by our proximity to the U.K.; for their problems are essentially those of the complicated chest wound or the chronic case. It is essential that all forward surgeons should be able to deal with the preliminary treatment of a penetrating or sucking chest wound, and even more essential that well-trained chest physicians should be attached to forward units.

Clinical Lessons

What have we learnt clinically from the surgery of this campaign? We will not enter into a description of all the various types of war wound, but simply list a series of facts that have emerged from the mass of clinical material and of questions that have been raised and still await solution.

Extensive Flesh Wounds.—These have a high operative priority—at least equal to that of the "bellies." Massive tissue damage leads to a severe degree of "shock," against which resuscitation is often of no avail and for which urgent radical surgery is the only life-saving measure. One other valuable lesson learnt was the great importance of rest and immobilization in these cases, either in transport or post-operatively, and irrespective of whether they are complicated by bony injury or not.

Gas Gangrene.—Compared with previous campaigns this nightmare condition was conspicuous by its absence. The majority of the relatively few severe cases were in German prisoners, who often took some time to collect. In an operation of this magnitude, to have recorded something less than 300 cases of anaerobic myositis can only be described as phenomenal. The reasons which may possibly account for this different picture are discussed in general terms later. When it did occur it still carried a 20% mortality. "Gas-gangrene cellulitis," became recognized more and more as a clinical entity as experience increased. Some 70 cases were reported, with a mortality of 10%. Gas gangrene at hospital level was negligible.

Abdominal Wounds.—This group of cases—a large one of approximately 5,000—has also produced extraordinarily good results. An overall mortality of around 30%—a figure which reports from the United Kingdom suggest is not markedly raised in the later stages of treatment—is highly creditable. This improvement is, we feel, not due to any one factor. Little change has been made in actual technique, but principles of treatment have been both standardized and adhered to. Penicillin has been used, and has certainly favourably affected post-operative complications, but has probably had little to do with the lowered death rate, as two-thirds of deaths from penetrating abdominal wounds occur within two days of operation. A strict routine of post-operative care has undoubtedly been an important factor.

Suturing of individual small-intestine wounds as against resection, unless the latter procedure is demanded by mesenteric vascular injury or massive damage, remains a firm principle; as does also exteriorization of large gut wounds—although this on the right side is by no means the ideal answer. Latterly in the smaller right colon wounds, suture with drainage, attachment of the sutured gut to the peritoneum, and even ileo-colostomies have been performed with success in well-selected cases. The formation of a good spur in colostomies wherever possible greatly facilitates secondary procedures.

Liver wounds that reach surgery have not given great cause for concern, and what trouble there has been is from bile more often than from blood. Fibrin foam as a haemostatic in this region is worthy of more extensive trial. A more conservative attitude regarding wounds of the renal parenchyma has produced good dividends—and we have learnt that the thoracic approach to the spleen is as good as any when the nature of the wound allows it. Of approaches in general, the rectus muscle split has steadily grown in popularity; but the golden rule of an incision sited as far as possible over the suspected lesion and big enough to give good exposure still holds. The value of a posterior drain, if necessary after removal of the coccyx, in rectal and pelvic colon wounds became obvious; and of drainage in general we would say, "Avoid drainage if possible, but if in doubt, drain."

Radiological examination has, in the presence of the very common multiple small wounds of present-day explosive missiles, assumed a relatively far greater importance.

Burns.—The conspicuous absence of severe burns has been one of the welcome and noticeable features of this campaign. Only about 1,000 burns were admitted to forward units, and only one-third of these were identified as serious. In this latter class there was a mortality of 5%. From the hospital angle, burns accounted for 3% of all admissions (surgical) and for 2% of all battle casualty cases. This very marked difference in comparison with the M.E. campaign leads one to suppose that climatic conditions, both directly and indirectly, must have a very big effect on the incidence of burns.

Treatment was of the simplest, and was standardized: as a preliminary (apart of course from the necessary resuscitation), gentle cleaning and the application of an oily dressing containing a bacteriostatic (sulphonamides or, later, penicillin). Burns were immobilized so far as was possible, and dressed as infrequently as possible. Cases which were considered too severe to be treated under this regime were skin-grafted during a course of parenteral penicillin—the most severe being, whenever possible, referred to plastic surgeons for treatment.

Chest Wounds.—In this field improvement came from the better appreciation of certain simple facts rather than any new technique. For example:—(*a*) That chest wounds do *not* travel well in the first five or six days and should be held in forward units until stabilized. (*b*) That there is no danger in emptying a pleural cavity far earlier than was previously considered advisable—i.e., within 12 to 24 hours. This emptying applies as much to air as to blood. In certain units the use of an apical tube for draining a pneumothorax was proving "practical politics." Many surgeons were emptying the pleura by catheter previous to inserting the last stitches closing a sucking wound, and at the same time the anaesthetist would expand the lung by positive pressure. The slogan produced by our medical colleague (Brig. E. Bulmer)—"Having saved the life, save the lung!"—has governed our policy in these chest wounds, and by far the majority of cases have shown a reasonably well expanded lung before transference to base hospital. When it has been difficult to achieve this, the cause is frequently a lung haematoma—a condition, it is felt, not hitherto sufficiently appreciated. What the late effects of this early definitive treatment will be in comparison with those of the last war and previous campaigns only time can tell—but we are hopeful. (*c*) That once a sucking wound is closed, penetrating chest wounds are better dealt with and supervised by a physician. Considerable time is required to produce optimum results—and for the forward surgeon time is usually at a premium. The forward physicians have in this campaign done yeoman service. (*d*) That chest cases, like all other serious wounds, are shocked and require resuscitation. Admittedly, in view of the site of the lesion, this should be carried out carefully and rather more slowly than is now accepted as usual. For the immediate resuscitation of chest cases blood is much safer and more valuable than plasma. The risks of producing pulmonary oedema by giving intravenous fluids are infinitely less than the risks run by not giving them at all.

At the end of the campaign the general impression regarding thoracic wounds is that there has been a very marked improvement in treatment and results as confidence grew from increased experience. So much is this the case that we feel, and have the agreement of our thoracic surgeons, that forward surgeons might well, with suitable direction, be a little more ambitious in the early stages, both with safety and with advantage to the patient.

Vascular Injuries.—Here is a surgical field still in the throes of exploratory tilling—and a very important field in its inevitable (at the moment) wastage of limb and life. The majority of our fatal cases of gas gangrene have been those associated with vascular damage, and a considerable percentage of the total amputations have resulted from irremediable injury to main vessels. No fewer than 1,150 cases (i.e., 2% of the total) were specifically recorded by forward surgeons. This group carried a 5% mortality. And at the end of it all we were still relying on ligature as the mainstay of treatment. The success or otherwise of this procedure depended upon a number of factors, such as length of time between wounding and operation, amount of associated muscle damage (i.e., obliteration of potential collaterals), site of vessel injury, amount of sepsis in the wound producing the vascular damage, and, even more important in distal wounds on the same extremity, extent and severity of accompanying wounds elsewhere and the patient's general condition. Even allowing all these variables, one often saw almost comparable cases—one viable, the other gangrenous. Arterial spasm is most certainly an entity, and the individual's sympathetic response to various stimuli is undoubtedly yet another factor.

Little benefit was achieved in these cases either by sympathectomy or by local stripping of vessel coats. Sporadic good results following arteriectomy were reported in cases of so-called spasms. The local and primary repair of a partial tear of a major vessel was also occasionally successful, but one felt always that there was too much of an element of luck in these cases to make them of any scientific value. The calf fascia-splitting incision (as popularized in C.M.F.) was found useful, but only in selected cases—where the lower leg was markedly swollen and cold and the skin glazed. The most stimulating line of advance was the work of certain surgeons (in particular Major W. Mustard, R.C.A.M.C.) in performing primary intubation of damaged major vessels. Tubes of glass and acrylic resin were used, the rationale being to restore circulation through the main vascular channels of a limb at the earliest possible moment, with the idea of removing the tube and carrying out definitive treatment (e.g., suture, venous graft, ligature) within a few days when circulatory stability had been regained and collaterals opened up. Results of this technique produced some unexpected and occasionally disquieting secondary phenomena—e.g., the effect of suddenly washing into the general circulation the metabolites of a limb in which the circulation had been stagnant for several hours. However, it is felt that along this line there is most chance of a material advance.

In the meantime, ligature, with all its chanciness, is still the accepted treatment. The ligatured popliteal still gives far too many bad results, the femoral prognosis is fifty-fifty, and the brachial good. We have learnt that it pays to keep these cases in forward areas for several days, until a definite decision as to the future of the limb has been arrived at.

Knee-joints.—A series of 1,365 penetrating wounds of the knee-joint, with only 7 deaths, would have sounded like the worst kind of fairy-tale in 1940, and even in the Middle East a large proportion developed pyarthrosis, with subsequent toxicity and disability. And yet these are the B.L.A. figures. The cases were treated by careful excision, by suture of the synovial layers without drainage, by the instillation of local penicillin (50,000 units) into the joint cavity, and by careful immobilization in a Tobruk splint for transit. At the same time a course of parenteral penicillin was instituted. Practically all these cases were transferred direct to the U.K. Later reports from orthopaedic centres there underline the really amazing change in the picture of these cases. So good was their general and local condition on arrival that there was at first a tendency to push convalescence a little too fast. A series of local, but unimportant, flare-ups in the joints with an effusion were evidence of this quite understandable over-enthusiasm. As examples of the later results extracts from two reports from the U.K. may be given.

(*a*) Series of 78 cases in a transit E.M.S. hospital in the first month of June, 1944. 44 had serious accompanying bone injury, 4 required amputation (2 for joint infection, 1 for popliteal artery damage, 1 for gas gangrene). At eight months 33% had flexion better than 90%, and another 15% better than 45%.

(*b*) A later series of 101 cases at an orthopaedic centre: Normal knee, 67; expected to be normal, 10; useful range, 13; ankylosed, 11; no deaths; no amputations. Only 9 cases had suppurative arthritis; 4 of these were healed within six months, three of them much earlier. Of the 11 ankylosed knees, 9 had marked bone damage. No drainage of an actual joint was ever necessary.

This is a stimulating picture, for which, of course, we must undoubtedly to a large extent thank penicillin; but, as ever, this invaluable agent should be thought of only as the handmaiden of good surgery. A comparison with German knee-joints is tragic. They perform large numbers of primary excisions, they drain every joint with outsize tubes, and their immobilization is minimal. Hence all their knee-joint cases are septic, and those who do not die of toxaemia either have to lose a limb or accept a deformed and useless one. So there is credit due elsewhere than to penicillin!

Amputations.—Little need be said on this subject. Approximately 3,200 amputations (excluding digits) were performed in this theatre—2,600 in forward areas with 7.5% of mortality, and 600 in base hospitals with 1.3% mortality. The principles of flap formation, of avoidance of primary suture, and of the use of delayed suture have been strictly adhered to. We have considered a guillotine amputation a surgical crime (it is the accepted German method!), and we have preached that amputations through joints should be performed only in cases of dire emergency.

Delayed Suture (with which should be grouped simple skin-grafting).—There is nothing dramatic about these techniques, but the results achieved have led to a saving of man-power, a reduction in wound complications, and an economy in hospitalization, in supplies of drugs and equipment, and in surgeons' and nurses' time which it is quite impossible either to compute or to appreciate fully. As holding capacity increased towards the end of 1944 in Belgium, more and more cases of at first simple flesh wounds and later of more complicated wounds (e.g., compound fractures were rendered "simple" before evacuation to the United Kingdom) were sutured in base hospitals. During the last six months of the campaign these cases provided more than 50% of the work in base hospitals, and during the process a great deal of interesting and valuable clinical and scientific research was carried out. This has been fully reported elsewhere ("21 Army Group Penicillin Therapy"). Results were universally satisfactory—90% sutures being considered not quite good enough!

It is impossible here to enter into the many points of detail which have been of interest, but perhaps one example may be quoted as being indicative of the saving of time, equipment, and energy resulting from such simple measures. Let us always remember, however, that it is only the laying of the bogy of wound sepsis by good preliminary surgery and by penicillin and its allies which makes this mass repair a practical proposition. The simplest type of wound—a "through-and-through" bullet wound of the soft tissues of the thigh—was produced by an officer (accidentally!) shooting his batman through both legs. The surgeon applied local penicillin and a sterile dressing to one entry wound and one exit wound; the other entry and exit he excised and three days later sutured. At the end of 10 days (i.e., a week after suture) stitches were removed from the sutured wounds, leaving a linear pliable little scar. The other two wounds remained perfectly clean and ran a normal course of healing; but they took 23 days before dressings could be discarded, and left "threepenny" slightly depressed scars, one of which was adherent to deeper tissues. A simple example of a very important advance!

Post-operative Complications

Most of these are too well known to merit discussion here, but we would like to record the very noticeable absence of post-anaesthetic chest complications throughout the campaign—even in the bitter weather of last Christmas in the snow of the Ardennes and the mud and chill of eastern Holland—and at the same time to pay tribute to the very high standard of anaesthesia that was maintained. But two complications probably remain in the forefront of the minds of most B.L.A. surgeons—fat embolism and so-called "anuria."

(*a*) *Fat Embolism.*—The occurrence of a small series of 5 cases (4 of which were fatal and 3 proved by post-mortem examination) in the early battles around Caen aroused our interest and prompted the thought that this little-understood and rather dire complication of trauma (or should one say mechanical and surgical trauma, and even add anaesthesia to the list?) was perhaps more frequent than had previously been thought the case. Subsequent investigations have certainly confirmed this supposition—but have unfortunately done little to elucidate the problem. We have learnt to recognize fat embolism clinically with much more accuracy, and hence can say that a larger proportion than 20% (as in the "warning" series) survive. Over 100 cases have been reported during the campaign, and doubtless many more have occurred. It would seem that the mortality is approximately in the neighbourhood of 50%. The following facts of interest have been noted often enough to be worth recording:

(i) Although usually the sequel of a major wound involving large masses of soft tissue, this is by no means always so. Cases have been reported several times after retroperitoneal haematomata, once or twice following chest wounds, and once with a straightforward penetrating abdominal wound involving small intestine only.

(ii) The old theory that the embolic fat is derived from the marrow of a broken bone is quite exploded.

(iii) The predominance of cerebral symptoms over pulmonary has been a striking feature.

(iv) Petechiae, most commonly seen over the shoulders, upper chest, and neck, were the exception rather than the rule.

While a considerable amount of research has been done in the theatre on this problem, it must be admitted that little light has been shed on the possible aetiology. Apart from symptomatic measures, the only definitive attempt at treatment, to our knowledge, was the intravenous injection of 90% alcohol. The patient recovered, but whether from fat embolism or acute alcoholic poisoning is not related!

(*b*) *Anuria.*—This aetiologically vague but clinically very definite syndrome was seen all too often in many of our more serious cases. During the V-bomb raids on Antwerp cases of "crush syndrome" were relatively common, but, apart from this better-known variety, cases were continually being discovered in which there was no suggestion of "crush" but in which anuria developed. Not by any means all were fatal, but, once established, the outcome of the case appeared to be in the lap of the gods. As time went on we had reason to doubt the value of intravenous alkalis, which we at first strongly recommended. Likewise, no success was obtained from high-spinal anaesthesia or from splanchnic block. The consensus of opinion at the moment would seem to favour the conjecture (and that is all it is) that a circulating toxin is produced by massive tissue damage—the effects of which are widespread. The kidney tubules are possibly one of the affected parts. It has been noted that the same toxin may act on normal blood fat in such a way as to change its physical state and render it more likely to be deposited in pulmonary and cerebral capillaries.

Naturally, in war, trauma—and severe trauma—is very much with us; but the possibility of both the above conditions occurring relatively far more frequently in civilian life than was previously recognized should be borne in mind. They offer a rich field for future research.

The Surgeons

Two out of every three B.L.A. surgeons—the men responsible for the work described above—had never met a war wound face to face before D Day and their arrival in Normandy. The remaining third were veterans of the M.E. campaign. The effect of the latter on the former, the effect of six months' training as a surgical team before D Day, the value of a routine procedure standardized so far as was possible and based on previous practical experience, are all borne out by the recorded results. The conservatism and judgment of the smaller group and the loyalty and willingness to learn of the larger—and, let it be fairly said, the excellent surgical technique of both—produced an atmosphere which was as stimulating and provocative as it was efficient and friendly. War surgeons are really quite an individual class—and are bred as much as they are born. They must be essentially competent technicians, with a good anatomical background—not too slow, not *too* meticulous—capable of endurance, blessed with common sense (which gives sound judgment) and human understanding, adaptable and cheerful—doctors as well as surgeons! Naturally there are many varieties of this prototype, and most of them are good. The war surgeon acquires enormous confidence. If he ever aspires to become a good surgeon he must possess or acquire a corresponding amount of clinical and technical knowledge.

In this thought lies a description of the three main classes of war surgeon: the one who will always be a menace, possessing only confidence; the one who was a surgeon before he was a war surgeon and will only have to readjust on return to civil life; and the one who has become, or, even more important, *may* if properly handled become, a good surgeon on the basis of his war experience together with a desire to acquire a wider knowledge.

Such were the surgeons of B.L.A., though Class I was almost conspicuous by its absence. They were good war surgeons, they were good friends, and they made a good team.

Summary

It has intrigued us to probe into the reasons for these improvements and for the general high standard of surgery in this campaign, considering that very little new has been added in technique and very little new has been discovered in research. Many are the discussions we have had on this subject in many weird places. The following points summarize our opinions:

1. *Man-power.*—Probably no group of surgeons ever worked on better material. The men of 21 Army Group were fully immunized and fully trained; their morale was at its highest—"the last lap" feeling; they were well clothed and well fed, fighting in a climate to which the average British soldier is more accustomed; hygiene, both personal and unit, was exceptionally good; and welfare services were excellently organized to cope with the leisure hours.

2. *Tactical Situation.*—21 Army Group was always a winning army! It had the initiative and could dispose its units as required. Air cover was to all intents and purposes complete, enabling patients to be held or transported in safety more or less at will. The modern type of warfare—essentially mobile and rapidly moving—ensured that units were never overwhelmed with cases.

3. *Surgical Policy.*—The standardization of policy, based on practical experience and inculcated into a united team previous to the beginning of the campaign, has already been discussed. To obtain optimum results we have attempted so far as was possible to have the individual surgeon working with compatible people at the right type of unit and at the right level. Having laid down a policy, which must of course be elastic enough to cope with changing circumstances and not so hidebound as to throttle reasonable initiative, we feel this placing of personnel and the dissemination of clinical (and topical!) news by constant personal contacts to summarize the duties and responsibilities of a consultant to his surgeons.

4. *Evacuation.*—Speedy collection of wounded has made early surgery possible, and the remarkable development of air evacuation has permitted early and more definitive surgery to be performed sooner than in any previous campaign. Provision for interim treatment during evacuation, whether by road, rail, sea, or air, has been brought to a high pitch of efficiency—and in this respect we would stress the importance of adequate immobilization, wherever possible, of a wounded part during transit.

5. *Forward Surgery.*—The gradual pushing forward of surgical potential (a process initiated in the desert by the first "mobile surgical teams" of Major-Gen. D. C. Monro) until an optimum level has been reached, considered by us to be C.C.S. level or theoretically

just on the corps side of the corps-divisional boundary, has ensured the wounded man getting as soon as possible to surgical care—the latter being provided in circumstances which afford the maximum facilities for surgeon and nursing staff and the maximum comfort for patient. This potential to-day is provided by that invaluable little self-contained unit the "field surgical unit."

6. *Pre- and Post-operative Treatment.*—There is no doubt that on both sides of the operating table considerable, if not dramatic, advances have been made. Resuscitation as provided by the Blood Transfusion Service has been in every respect admirable. They were responsible not only for actual resuscitation, both pre- and post-operative, but also for the selection of priority cases awaiting operation—a task demanding the soundest clinical judgment and common sense. They also delivered to all units requiring them supplies of blood, plasma, saline, glucose, and penicillin as if by divine inspiration, no request ever having to be made and no notification having to be given of change of location—even to the most out-of-the-way spot. Indeed, the supply system as interpreted by our Base Transfusion Unit might well serve as a model for the cutting of red tape during action. The gay good humour of all the B.T.U. personnel, even under the most trying and difficult circumstances, was an inspiration to all with whom they came in contact.

So also was the presence of nursing officers in forward surgical units. Much of the vast improvement in post-operative treatment (and with its penicillin injections and drips, its intravenous infusions, its gastric suctions, its morphine, its sera, apart from all other routine nursing requirements, this is a complicated ritual to-day) was due to their excellent work. Added to this, too, is the undoubted value of a woman's presence both beside the bed of a recently wounded man and in the wards and theatres with the male personnel. In both spheres they have done much to raise morale, and their cheerful but quite obviously genuine enjoyment of their arduous and often dangerous work is deserving of the highest praise. In this connexion, too, mention must be made of our B.R.C.S. services, under the able and kindly direction of Major-Gen. Lindsay. They never failed, even in the most forward areas, to provide those little comforts and that personal attention which mean so much to a wounded man, and incidentally to his surgeon, who benefits from his patient's raised morale.

7. *Penicillin and Sulphonamides.*—Sulphonamide therapy was well established previous to this campaign, but in our lavish supplies of penicillin we have certainly been most fortunate, and to its beneficent effect must go considerable credit for the results achieved. Its prophylactic use on the scale employed in Normandy was an entirely new venture and paid handsome dividends. Since then both prophylactically and therapeutically it has been used to an increasing extent with consistently good effect. Among other clinical researches carried out in Army Group (and described in full in "21 Army Group Penicillin Therapy") was one which proved that penicillin alone offered as good protection against wound infection as did a combination of penicillin and sulphonamide.

8. *Surgeons and Surgery.*—By no means least has been the effect of consistently good surgery carried out by an enthusiastic and capable team of surgeons. We had but two women surgeons; we had many women anaesthetists, radiologists, and surgical general-duty officers—far more than any other theatre of war had ever dreamt of. Let it be said that their part in this saga was not one whit less praiseworthy than that of their male counterparts. We were very, and we think justifiably, proud of our whole team.

Conclusion

As was stressed at the beginning of this article the success of a medical service depends essentially on close collaboration and mutual understanding between the administrative and clinical sides, and it is with very genuine feeling that we express our gratitude for their unfailing and full co-operation, to our two Ds.M.S. (Major-Gens. Sir Percy Tomlinson and E. Phillips), to the D.Ds.M.S. Armies (Brigs. E. Phillips, Galloway, and Glyn-Hughes of Second British Army, and Brigs. Fenwick and Elder of First Canadian Army), to the D.Ds.M.S. Corps and to the Consulting Physician (Brig. E. Bulmer), all the clinical advisers of Army Group, and to the surgeons, nursing officers, and other ranks, both male and female—all of whom have contributed materially to making our task as pleasant personally as it was fascinating surgically.

B. M. Schwartz (*J. Amer. med. Ass.*, 1945, **128**, 704) records his observations on 14 cases of Vincent's angina treated with penicillin. The recommended dose is 100,000 units, administered intramuscularly in 20,000 units every three hours, and was found to be of definite value. P. L. Shallenberger, E. R. Denny, and H. D. Pyle (ibid., p. 796), who also treated 14 cases of Vincent's angina with penicillin, obtained equally good results from intramuscular injection.

THE MIKULICZ RESECTION OPERATION FOR GANGRENOUS INTUSSUSCEPTION IN INFANTS

BY

T. A. HINDMARSH, M.S., F.R.C.S.

A. W. STEWART, F.R.C.S.

AND

B. MORRISON, M.D.

(*From the Royal Victoria Infirmary, Newcastle-upon-Tyne*)

When in an infant an acute intussusception becomes irreducible and gangrenous, not only is the choice of a suitable operation difficult but the results are usually bad. The operation commonly chosen in these cases is either resection of the gangrenous mass with end-to-end or lateral anastomosis, or exteriorization of the mass with the formation of an enterostomy, with a later attempt to close this if the child survives. Suture of the proximal part of the intussuscipiens to the intussusceptum has also been suggested, leaving the gangrenous mass to slough and pass per rectum. These operations are far from satisfactory; very few children survive.

In view of these results we have recently chosen to treat the irreducible gangrenous intussusception by a modification of the Mikulicz type of resection, and we are able to report here two successes. We recognize the danger of generalizing from two cases, but the results in these were so much better than we have experienced with other methods that we feel justified in publishing this report. At this point, however, we wish to make clear our view that no major operation of this sort in an infant will be successful unless the child is given special pre-operative and post-operative treatment by those who are experienced in modern paediatric methods and can judge from hour to hour what measures are required to be taken. A note by Dr. Brenda Morrison on these measures is included in this paper.

The Mikulicz type of resection which we recommend is made possible in infants because at that age the caecum, ascending colon, and transverse colon are very mobile. In both of our cases it was found easy, after a small incision of the peritoneum on the outer side of the intussusception, to mobilize the mass and to bring it out of the abdomen with very slight trauma, thus leaving the next steps of the operation to be performed expeditiously and with relative ease. The operative procedure followed in both cases was similar. A preliminary attempt at ordinary methods of reduction having failed, the intussusception was found to be gangrenous, and some form of resection was therefore necessary. The viable portions of the ileum and colon were quickly joined together, in the usual double-barrelled Mikulicz colostomy method, by two layers of continuous catgut sutures, and the abdominal incision was closed around the bowel by interrupted sutures. The condition of both cases at the end of operation was satisfactory. After six days the spurs were crushed and removed by the ordinary Mikulicz method with small crushing clamps. Six days later—i.e., on the twelfth day after operation—the stomata were closed after the bowel ends had been freed and inturned.

Case I has now made an excellent and permanent recovery. The patient has gained satisfactorily in weight, and a slight tendency to diarrhoea, due to loss of the ileo-caecal junction, has cleared up. The second case has made an excellent recovery after operation, and it is anticipated that this patient also will return to normal health.

Case I

On Oct. 11, 1944, two and a half days before admission to hospital, the patient, a female child aged 5½ months, started to cry suddenly and became deathly pale. Towards evening she became drowsy and difficult to feed. The doctor was sent for, and he put her on a glucose mixture. She was thought then to be suffering from a chill due to her teeth. The next day she appeared to revive to some extent. At 10 p.m. she was violently sick and the vomit was bright green. She looked very white and it was difficult to rouse her. She slept intermittently on the night of Oct. 12, and on the morning of the 13th she whimpered and vomited repeatedly, but did not appear to be in severe pain. Later in the day she was admitted to the children's department of the Royal Victoria Infirmary under Prof. Spence. No blood had been passed per rectum before admission and there had been only one small motion.

On admission she was found to be well nourished; her expression was anxious, eyes sunken, and tongue dry. The abdomen was slightly distended, and there was a readily palpable, sausage-shaped tumour in the left flank extending down into the pelvis. Per rectum no mass was palpable, but some foul-smelling blood-stained fluid emerged on withdrawing the finger.

After pre-operative treatment had been carried out, at 4.30 p.m. one of us (T. A. H.) opened the abdomen through the usual lower right paramedian incision. A large intussusception was found extending well down into the descending colon. Attempts to reduce the mass inside the abdomen were not successful, and it was delivered out of the wound with some difficulty. After a portion of the intussusceptum had been reduced it was found that the remainder was completely gangrenous. The mass was then rapidly mobilized and removed by the modified Mikulicz method described; the loop was brought outside the abdomen, and healthy portions of the lower ileum and transverse colon were sutured together side by side. After the abdomen was closed the gangrenous loop was removed, and catheters were tied into the ends of the ileum and colon for drainage purposes. The opening was later dealt with as previously described, and the child ultimately made an excellent recovery.

Case II

This patient was a male child aged 10 months. On May 9, 1945, four days before admission, he vomited, and later in the day had attacks of crying. Between the attacks he lay quiet and looked very weary. All that night he vomited everything he took and had spasms of crying. Early next morning he passed a small reddish motion. There was no visible blood. The vomiting and screaming continued all day and the child seemed to become weaker. He lay very quiet between the attacks. The doctor was called in and prescribed a stomach mixture. On the 11th he was still vomiting, but was not crying nearly so much; he appeared very exhausted and whimpered occasionally. He continued like this until his admission to the children's department of the Royal Victoria Infirmary on May 13. The bowels had not moved since May 10 and there had been no frank blood passed per rectum.

On admission he was an obviously ill baby, pale and worn out, lying quietly with partly closed eyes. There were obvious signs of dehydration, but the nose and extremities were warm. The heart rate was 140. The abdomen was distended and tympanitic. There was guarding in the right hypochondrium and a suggestion of fullness, but no tumour was felt. Per rectum no mass was palpable, but on withdrawing the finger a small amount of brownish fluid was passed.

An intravenous drip was started immediately, and three hours later one of us (A. W. S.) examined the child under an anaesthetic. A fullness was felt in the epigastrium but no definite tumour. The abdomen was then opened and a small ileo-colic intussusception was found, extending to the middle of the transverse colon. Reduction inside the abdomen was unsuccessful, and the whole mass was delivered outside the abdomen with some difficulty. Some ileum was then reduced, and it was found that the remainder was obviously gangrenous. The mass was accordingly mobilized in the manner previously described, and healthy portions of ileum and ascending colon were secured together by two layers of continuous catgut sutures. After the abdomen had been closed the gangrenous mass was excised and catheters were tied into the ends of the ileum and colon for drainage purposes. The opening was later dealt with as described.

Pre-operative and Post-operative Treatment

Case I.—An intravenous drip infusion was set up on admission and 100 c.cm. of 0.2% saline with 4% dextrose was given before operation. The drip was continued during the operation and afterwards for six days. The total amounts of fluid given over this period were: 350 c.cm. pooled human serum, 200 c.cm. fresh whole blood, 300 c.cm. normal saline, and 1,600 c.cm. 0.2% saline and dextrose. In addition substantial amounts were taken by mouth (see Table I). Her immediate post-operative condition was fairly good—the heart rate was 200 per minute, but she was hydrating up and the circulation was satisfactory. The ileostomy did not drain at all for the first 36 hours, although the tube was patent, but the baby vomited only twice and took small drinks well. On the evening of Oct. 14, however, she began to deteriorate, becoming restless, pallid, and anxious. By the next morning she appeared moribund; the temperature was 98°, but the heart rate 190. She was sunken-eyed and cyanosed, moaned continually, and was very restless. She vomited dark-green fluid, and a further 300 c.cm. was removed from the stomach by aspiration. During the morning the ileostomy began to drain, dark-brown fluid faeces coming down the tube in spurts with each peristaltic wave. Several ounces had drained after a few hours, and the child became more restful and less fluid was aspirated from the stomach. By next day (Oct. 16) the bowel was draining well and the child was considerably improved. Blood examination at 8 p.m. on Oct. 15 had shown a marked anaemia of post-haemorrhage type: haemoglobin, 50% (7 g./100 c.cm.); R.B.C., 2,800,000; haematocrit, 20%. Blood urea was 64 mg. per 100 c.cm.; plasma protein 6.4%, and plasma chloride 320 mg. Cl per 100 c.cm. plasma (normal range 340–380 mg.). A transfusion of 200 c.cm. of fresh blood plus 100 c.cm. of normal saline was given over 16 hours; after this the blood picture was: haemoglobin, 90% (12.7 g.); R.B.C., 5,200,000; haematocrit, 37%. Blood urea was 35 mg., plasma protein 5.8%, and plasma chloride 310 mg. Cl per 100 c.cm. (Oct. 18). She was able to take fluids by mouth from Oct. 16, and was given 1 oz. hourly for three days, then 2 oz. two-hourly for 4 days. She fed fairly well, with only occasional vomits. Fluids given were water at first, then 1 in 8 dilution Nestlé's milk, then humanized Trufood.

TABLE I.—*Case I. Showing Fluid Intake and Output, with Blood Chloride Levels, during the First Week*

Date	By Drip (c.cm.)	By Mouth (c.cm.)	Aspiration and Vomits (c.cm.)	Blood Cl Level (mg./100 c.cm.)
13/10/44	230	60		
14/10/44	300	450	100	
15/10/44	420	300	500	320
16/10/44	300	350	50	
17/10/44	400	600	45	
18/10/44	400	400	0	310
19/10/44	400	400	0	

The interesting features were (*a*) the marked anaemia, which was almost certainly a result of haemorrhage into the bowel, as she passed three large stools after operation, consisting almost entirely of altered blood; and (*b*) the low blood chloride level.

Case II.—On admission this baby was in a state of established dehydration, with sunken eyes, inelastic skin, and greyish pallor. He was given 200 c.cm. of plasma in 1½ hours before operation and improved considerably, his face and lips becoming pinker. 50 c.cm. of fresh blood was given during the operation, and the drip was continued afterwards at a rate of 100 c.cm. of fluid every six hours. Normal saline and 0.2% saline and dextrose were given alternately for the first 36 hours, then plasma and normal saline alternately, and later normal saline and 0.2% saline again. Altogether the drip ran for 4½ days, and the total amounts given were: 450 c.cm. plasma, 50 c.cm. fresh blood, 1,250 c.cm. normal saline, 950 c.cm. 0.2% saline and dextrose. The stomach was aspirated every 4 hours for the first 3 days. He was given fluids by mouth from the start and drank well throughout. At first there was very little fluid obtained by aspiration from the stomach and no vomiting, and the child appeared fairly fit. However, on May 14—i.e., 48 hours after operation—his condition deteriorated considerably. He became sunken-eyed, with cold extremities and frequent restless spasms. Dark-green fluid was now aspirated from the stomach in large quantities and nothing was draining from the ileostomy. The blood chloride level was 305 mg. Cl per 100 c.cm., plasma protein 5.6%, and blood urea 58 mg. per 100 c.cm. It seemed that large amounts of fluid and salt were accumulating in the small intestine, and, though peristalsis was audible, drainage was not yet established. The chloride intake per drip was increased. During the next 24 hours drainage via the ileostomy became established and the amount removed by gastric aspiration lessened steadily. The patient's condition improved considerably, but he still appeared very dehydrated. By 10 a.m. on May 16 he was drinking eagerly and not vomiting, but the blood chloride level was down to 285 mg. Cl per 100 c.cm. The blood urea was then 23 mg. and haematocrit 36%. He was passing very little urine and still looked dehydrated. Two oz. of normal saline was given by mouth, alternating with 4 oz. of Trufood and Prosol mixture every two hours; he drank all this eagerly, taking unusually large amounts of fluid and sodium chloride for a baby of his age (see Table II). By May 18 the chlorides were up to 321 mg. and he appeared much better hydrated. The ileostomy was now draining soft semi-solid faeces. By the end of the week he was definitely out of danger and appeared remarkably well and contented.

TABLE II.—*Case II. Showing Fluid Intake and Output during the First Week*

Date	Intake		Output		
	By Drip (c.cm.)	By Mouth (c.cm.)	Aspiration and Vomits (c.cm.)	Ileostomy (c.cm.)	Urine (c.cm.)
12/5/45	300				
13/5/45	400	90	50	10	30
14/5/45	600	720	560	30	90
15/5/45	700	540	360	300	60
16/5/45	600	580	0	140	60
17/5/45	100	1,230	0	?	
18/5/45	0	2,220	270	?	

The interesting feature of this case was the very low level reached by the blood chloride, and the amazingly high intake of sodium chloride by mouth and drip, which was very well tolerated; in fact, he showed great eagerness to drink the normal saline and never refused any of it during the period of chloride deficiency. The estimated intake of sodium chloride per day is shown in Table III. This does not include the salt content of the milk food (Trufood and Prosol).

TABLE III.—*Case II. Showing Estimated Sodium Chloride Intake (apart from the Salt contained in the Dried Milk) and Plasma Cl Levels during the First Week*

Date	NaCl Intake (g.)	Blood Chloride (mg./100 c.cm.)
13/5/45	2·9	
14/5/45	3·4	305
15/5/45	6·4	
16/5/45	4·8	285
17/5/45	10·8	
18/5/45	11·1	321

Comment

It is of interest that both these children were most profoundly ill about 48 hours after operation, with signs of intestinal obstruction, which was relieved when drainage from the ileostomy became properly established.

It is worth pointing out what large amounts of fluid, such as 0.2% saline and dextrose or normal saline, can be taken by mouth and retained by these ill children in addition to fluids given intravenously.

Summary

We report two cases of gangrenous intussusception, of two and a half and four and a half days' duration respectively, treated by a modified type of Mikulicz resection.

We consider that this method of treatment can be expeditiously carried out and that it offers a better chance of recovery in the "bad-risk" case than the ordinary methods of treatment recommended, such as end-to-end anastomosis or lateral anastomosis after resection or enterostomy.

We wish to emphasize the necessity for treating this type of case in a properly staffed and equipped children's department, as we feel that skilful pre-operative and post-operative treatment must play a major part in the recovery of these patients

TRICHOMONAS VAGINALIS INFECTION IN THE MALE

BY

F. L. LYDON, M.B., M.R.C.P.
Major, R.A.M.C.

The frequency of *Trichomonas vaginalis* infection in the female has for many years been recognized, but the similar infection in the male has not received the attention it merits, since it is by no means an uncommon cause of urethritis. During the past few years I have seen numerous cases of this nature, some of which I was fortunate enough to observe over many months, and the results of my investigations are put forward in the hope that with a higher index of suspicion when confronted with a "urethritis," especially one showing a tendency to relapse and chronicity, other workers will discover that many of these cases are due to infection with *T. vaginalis.*

The Organism

The description of the organism as regards size, shape, flagella, etc., may be found in most laboratory textbooks, but I would like to add some personal observations.

(*a*) *Shape.*—Although usually described as round or pear-shaped, I have seen in some preparations what appeared to be a stoma at the flagellated extremity, suggesting that the organism is in fact globular when not subjected to pressure. The flagella therefore may act primarily as a means of directing food particles into the body of the organism and not for the purpose of locomotion.

(*b*) *Method of Reproduction.*—It is, I think, generally assumed that reproduction is by simple fission, but on two occasions I have watched for a period of two hours a process best described as "budding." In one case a large organism (parent cell) was attached to a much smaller one (daughter cell) by a bridge of clear cytoplasm, the outer covering of both organisms being continuous. Separation resulted by the stretching and final rupture of this bridge owing to the action of the flagella of each organism in opposite directions. After separation the daughter cell was morphologically identical with the parent, though much smaller in size (6–8μ). On the second occasion (one parent and two daughter cells) the same appearances and results were observed.

(*c*) *The Occurrence of a Resting Phase.*—In some of my cases the active organism disappeared completely from the discharge for periods varying from about one week to two months. During these intervals, however, cells with a "hard" limiting membrane could always be found on dark-ground examination, which suggested that the organism had entered an encysted stage. Differentiation between these cells and some medium-sized epithelial cells is extremely difficult, but a certain facility is acquired by experience. If confirmed this observation of a resting phase is obviously of great importance both in diagnosis and in assessment of cure.

(*d*) *Method of Demonstrating the Organism.*—For convenience and clarity the dark-ground method is by far the best for the clinician. A drop of normal saline is placed in the centre of a slide. A loopful of the discharge is now dipped into the saline until the fluid takes on a slight opalescence. Recognition of the degree of opalescence necessary comes after a little practice, and I find that holding the slide to the light and looking at the fluid through the glass is of great assistance. A cover-slip being applied, dark-ground examination is carried out in the usual manner.

Pathology

Much divergence regarding the pathogenicity of the *T. vaginalis* is found in the literature: some support its claim as the primary pathological cause, while others look upon it as a parasitic invader following a primary bacteriological infection. Undeniably this latter view is supported by the marked number of organisms found in stained smears of *T. vaginalis* urethritis even on the second day of the appearance of the discharge; in fact, in my department, in any case in which stained smears of urethral discharge show large numbers of organisms the presence of *T. vaginalis* is suspected, and often confirmed. In spite of this, however, I feel that at the moment the problem is best considered in the same light as a Vincent's infection of the mouth, where somewhat similar conditions are necessary for the development of the disease—i.e., dead or damaged organic tissue on which the two organisms flourish together, each being necessary for the development of the other owing to some mutual symbiotic characteristics. This view saves a great deal of useless argument, since either *T. vaginalis* must be first grown in pure culture (or one of the many bacteria present) and shown to produce the disease before the problem can be finally settled.

Turning to the condition in the female, the marked preponderance in young unmarried women is of great interest, and in my opinion one must consider the possibility of extension to the vagina from the bowel in spite of the insistence by some workers on the specific nature of this organism for the vagina. It is well known that cyclical changes (in the vagina) occur, which cause a denudation of the vaginal mucous membrane at regular intervals, and this fact must, owing to poor drainage in young women, bring about a favourable nucleus for the invasion of parasitic organisms. Again, organisms very similar to *T. vaginalis* are often found in the *intestine*, and unless evidence as to the specificity of *T. vaginalis* is beyond doubt, one feels that here at least is a reasonable explanation of the method of infection.

With regard to upward extension of the pathological process, recurrent attacks simulating pyelitis have been common in my experience, but there has been no involvement of the prostate, epididymis, or testis. Cases of prostatitis have been described in the literature, but I doubt if this occurs, since microscopical examination of prostatic fluid (obtained after previous posterior irrigation with two pints of normal saline) always yielded negative results even in the very chronic cases. The possible admixture of anterior urethral pathology with prostatic fluid due to the common, and to be condemned, practice of "milking" the penile urethra after prostatic massage has, I believe, led to such erroneous conclusions. The rarity of stricture (in only one case was a possible previous history of gonorrhoea obtained) is surprising when one considers the chronicity and the marked destruction of the urethral epithelium in this infection. In my opinion this indicates that the infection is localized purely in the mucous membrane, the submucous coat being unaffected. Concomitant gonorrhoea I have not seen, although I have examined gonorrhoeal pus by the dark-ground method on numerous occasions.

Description of the Condition

The incubation period is about three to four weeks, and the first sign is a feeling of irritation and itching in the anterior urethra. This is followed in 24 to 48 hours by a urethral discharge. On inspection the meatus is of a dull hyperaemic type rather than the brightly inflamed one found in acute gonorrhoea. The discharge, although abundant, is not so profuse as in Neisserian infection, and it has a characteristic "watered milk" appearance, due probably to the high proportion of epithelial cells relative to pus cells in the discharge, and this colour is in marked contrast to the yellowish pus of a true gonorrhoea. Dysuria is absent, and frequency is not a pronounced feature. Urgency I have not seen, even when the 2- or 3-glass test suggested upward extension. The appearance of the urine is rather typical. It is hazy, with innumerable small flakes or specks, this again being an indication of the denudation of the surface epithelium which is so common a feature in these cases. The subsequent course of the infection is one of great chronicity, characterized by waxing and waning of the objective signs and the microscopical picture as indicated earlier in this paper, whether treated by the many methods advocated or merely just allowed to go without any treatment. I am convinced that the discharge may be so slight that the presence of the infection is completely overlooked during the resting-phase period, leading to false optimism of cure until some factors, at present unknown, provoke a recurrence of the discharge. The chronicity of the infection is well illustrated by a case at present under my care, in which everything points to an infection contracted nearly four years ago and which has recurred with monotonous regularity over these years. It may be urged that there is the possibility of reinfection in this case and that the previous attacks may have been Neisserian, but the history of the condition since its origin leaves me in no doubt that the original infection was due to *T. vaginalis*. Other cases observed over two years also lend support to this view. The above description applies to the usual course, but I feel that there are many cases in which the initial infection is so slight that it is entirely overlooked by the patient, until conscience, after an exposure, leads to self-inspection and a slight morning gleet is discovered: examination at a V.D. centre dubs these cases as "urethritis," which leads to frequent attendances and many investigations, and often the correct diagnosis is missed unless the pathology of this disease is thoroughly understood.

It remains for the pathologists to discover the method whereby the *T. vaginalis* can be identified with certainty during its resting phase, as with experience I am finding that cases which showed many active organisms at one visit have for periods up to two months—as one at present under my care—shown nothing but the resting phase. Lack of time has prevented me from devoting much attention to this aspect of the disease. One last point in the clinical description of these cases is that in patients with a long prepuce the preputial mucous membrane sometimes shows the typical salmon-pink appearance often found in the female vagina. Urethroscopic appearances have varied in my hands and, so far as I can judge, there is nothing typical to be seen.

Treatment

Like all chronic conditions, especially when subject to remissions, one finds a multiplicity of "cures." Personally I do not think that at the moment we can claim to have any specific treatment for the condition, since, although many methods advocated do bring about amelioration of the signs, the propensity to relapse is similar to that in the female even when no further exposure is possible. It is essential, therefore, to prolong surveillance over many months, and in my hands the results to date of all treatments, including penicillin and the sulphonamides, have been most disappointing. Recently the administration of mepacrine hydrochloride, both by the usual dosage and by the intensive method now employed for malaria, has been tried, but although the discharge decreased to a very slight amount and the active organism disappeared from the discharge, the tell-tale resisting cell could still be found on careful search. That drug will, I believe, prove a failure, too, when subjected to the test of long surveillance.

Summary

The results of over two years' investigations and observation of cases of *T. vaginalis* infection in the male are presented above, and although it is only one part of the problem of "urethritis" its importance is stressed, since it has led to frequent invalidism and hospitalization, and the condition is as yet only dimly understood.

HERPES ZOSTER AND CHICKEN-POX

BY

JAMES TAYLOR, C.B.E., M.D., F.R.C.P.

Consulting Physician to the National Hospital, Queen Square, and to Moorfields Eye Hospital

Herpes zoster is a condition which has excited interest at various times. It has been noticed to occur in epidemic form, and, as one friend in a large general practice observed to me, "If I see one case of herpes I always expect to see several."

Some years ago it was believed—and the belief was shared by that great clinical observer Sir Jonathan Hutchinson—that second attacks of herpes never occurred. This view is no longer upheld. Some years ago I saw at Moorfields a patient with herpes zoster. On being told that the condition was "shingles" he said, "Oh, I had an attack of shingles 18 years ago on my neck." On examining his neck I found the scars of what must have been a pretty severe attack of herpes. I also saw with Dr. Robertson Fullarton a patient with severe post-herpetic pain in the face. This patient had had an attack of intercostal herpes a year before. I saw, too, with the late Dr. Lewis of Hampstead a lady with facial herpes who a year earlier had had an attack of occipital herpes for which Dr. Lewis had attended her.

Herpes, it will be seen, occurs in several regions. The intercostal is probably the commonest, and the cases I have met with in children have all been in this area. It should be mentioned, however, that the condition is never so painful in children as in adults, and the post-herpetic pain, so often very troublesome and persistent in the latter, is usually slight and of brief duration in the former. Besides the intercostal area almost any other nerve area may be the site of herpes, such as the shoulder, the neck, the buttock or thigh, and the face. When it occurs in the face area there is always danger of affection of the conjunctiva and subsequent impairment of vision. In one patient whom I saw with Dr. Melvill Green—the most severe case I have ever seen—three areas were simultaneously attacked—the face area, the shoulder area, and the intercostal. This patient did not recover.

In 1917 Dr. W. P. Le Feuvre published a paper dealing with the association of herpes and chicken-pox, and summed up by urging that herpes, on account of the close and probably causal connexion between the two diseases, should be a notifiable disease. In four years he took notes of 7 cases of chicken-pox in children following herpes in a parent. Three of these cases occurred in his own practice, the others he met with accidentally. He refers to 17 cases noted in the correspondence columns of this *Journal* between May and Oct., 1913, and reference is also given to a paper read by Dr. Bokay at the International Congress of Medicine at Budapest in 1907 in which 9 cases were described similar to those mentioned. These cases, together with two of his own, were published by Dr. Paul Heim in the *Berliner klinische Wochenschrift* in Dec., 1912.

In an analysis of the cases seen or published Dr. Le Feuvre notes three classes: (1) chicken-pox in one individual apparently contracted from herpes in another—41 cases; (2) herpes in one individual who had been in contact with a patient with chicken-pox—5 cases; (3) herpes and chicken-pox occurring simultaneously in the same individual. He also mentions several cases in which a parent the subject of herpes had been warned to look out for chicken-pox in the children. In these cases confirmation of the justice of the warning occurred usually in 14 days.

Some years ago I published (Taylor, 1920a) a paper in which I recorded some cases showing the apparent connexion between herpes and chicken-pox. In a subsequent paper (Taylor, 1920b) I returned to the subject, and reference is there made to several cases communicated to me by the medical men who had observed them. In the years that have since passed I have had several experiences confirming the close association of the two diseases, and I have been impressed by the fact that very often isolated vesicles quite indistinguishable from those of chicken-pox will be found in different parts of the body in patients suffering from herpes. It was no doubt an extreme case of this nature which justified Dr. Le Feuvre in describing the third class of these cases—herpes and chicken-pox occurring simultaneously in the same patient.

There certainly seems to be a strong case for adopting Dr. Le Feuvre's suggestion for making herpes a notifiable disease.

RAT-BITE FEVER DUE TO CAT-BITE

SATISFACTORY RESPONSE TO PENICILLIN AFTER FAILURE OF ARSENOTHERAPY

BY

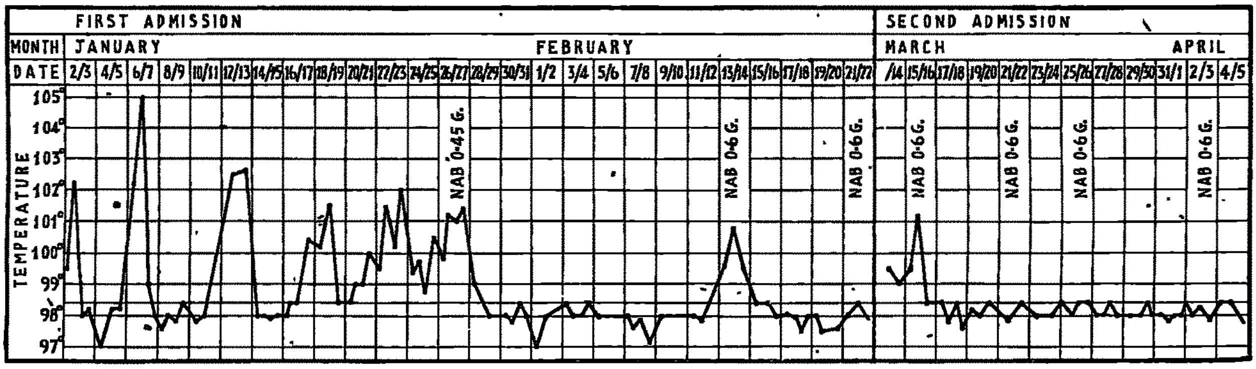
G. I. M. SWYER, B.M., D.Phil., M.R.C.P.
R.M.O., the Royal Masonic Hospital

Rat-bite fever (sodoku), though common in some parts of the world, is a rarity in this country; even when cases occur here they are less likely to result from the bite of a rat than from that of another animal, most often the cat. The following report of a case of cat-bite fever is thought worthy of record, especially as it presented some striking, though less generally stressed, clinical features, and was cured by penicillin after the repeated failure of arsenotherapy.

Case Report

First Admission.—A lieutenant in the Royal Engineers, aged 36, was admitted to the Royal Masonic Hospital on Jan. 2, 1945, complaining of intermittent feverishness since Dec. 24, 1944. His history included one attack of benign tertian malaria in 1935 and two attacks of sandfly fever in 1940 and 1944 while in the Middle East.

During the first week of Dec., 1944, while in Taunton, he was bitten on the middle finger of the left hand by a kitten. The wound bled somewhat, and he applied a strong solution of iodine within a short time. Some desquamation followed, which he attributed to the iodine, but within four or five days the wound had healed completely. On Dec. 24 he suddenly began to feel very tired and generally unwell. The finger became painful and inflamed, and he complained of soreness over the left side of his chest, with pain in the left axilla and supraclavicular region; temperature over 100° F. He took to bed. Next day the temperature had fallen to normal by noon, but his appetite had gone, and by the evening he felt chilly, tired, and depressed. His condition remained more or less unchanged until Dec. 27, when his temperature rose to 103° F. and his doctor was called in. In addition to headache, pain in the left chest, and cough, there were rhonchi at both lung bases, with a pleural rub at the angle of the left scapula. On Dec. 30, though he felt no better, his temperature had fallen to normal and his chest was practically free from physical signs, but a macular non-pruritic rash had appeared. On the 31st there was an exacerbation of symptoms, with a rise of temperature to 103° F. and pain in the upper jaw, associated with some swelling of the gum around an upper molar. By Jan. 1 his condition had further deteriorated and some blood was observed in the sputum. A few scattered rales were heard over both lungs posteriorly. Next day he was sent into the Royal Masonic Hospital with the tentative diagnosis of pleurisy.



On examination the patient looked ill; his face was flushed and he perspired profusely. There were several roughly circular reddened urticarial patches, averaging 2 to 3 cm. in diameter, scattered irregularly over the body, mostly on the neck and shoulders, with a few on the forehead, trunk, and extremities. They blanched on pressure and showed slight central vesiculation. An enlarged tender lymph node was palpable in the left axilla, and there were also a smaller left epitrochlear and a left supraclavicular node. The fauces and posterior pharyngeal wall were somewhat reddened; the tongue was clean and moist. Apart from tenderness in the left pectoral muscles the chest presented no abnormalities, and the cardiovascular system was not abnormal. The spleen was felt two finger-breadths below the costal margin; it was not tender. The C.N.S. presented no abnormal signs. The healed cat-bite could be seen; it did not appear to be inflamed.

Investigations.—Chest radiographs: No lesion seen. Blood count: Erythrocytes, 4.5 millions per c.mm.; Hb, 87%; C.I., 0.96; mean cell diameter, 7.17μ; leucocytes, 5,000 per c.mm.—neutrophils 2,950, eosinophils 100, basophils 0, lymphocytes 1,750, monocytes 200. No malaria parasites or pigment seen. Urinalysis: Sp. gr. 1010, reaction acid, no albumin or sugar; trace of acetone. Blood cultures taken on Jan. 3, 6, and 12 grew no organisms after seven days' incubation. Cultures from skin lesions grew only *Staph. albus*. Stool negative. Blood W.R. negative. Routine agglutinations to enteric and dysentery organisms, and to Brucella, within normal limits.

The course of the fever is adequately shown in the accompanying chart. During the febrile periods there was an exacerbation of symptoms, with anorexia, nausea, and increased prominence of the skin lesions. On the fourth day after admission he had a rigor, and tepid sponging became necessary next day because of a rise of temperature to 105° F. With the recurrence of fever on the 10th day after admission stiffness occurred in the arms and legs, which felt as though they were swollen, though no swelling was detectable. This symptom persisted for many days. Examination of the patient at this time revealed a picture similar to that on admission, except that the spleen was no longer palpable and the lymph nodes were smaller and not tender. Blood examination for spirilla (direct film) while the temperature was elevated (16th day) was negative. During the next febrile period blood was inoculated into some mice, while scrapings from the skin lesions were inoculated into others; about a week later the mouse blood contained organisms morphologically indistinguishable from *Spirillum minus* (Carter). Neoarsphenamine, 0.45 g., was then given intravenously; next day the temperature fell to normal, accompanied by profuse sweating, nausea (with vomiting on one occasion), and a widespread macular rash on the trunk and arms. This last had the general appearance of a drug eruption, and was presumed to be due to the arsenic.

The patient remained afebrile for the next 15 days. He felt rather unwell for two days after the arsenic injection, but soon became symptom-free, while the drug rash and the specific skin lesions rapidly disappeared. On Feb. 12, however, the temperature began to rise again; symptoms were slight, and included some tenderness of the muscles of the right arm. A prominent skin lesion appeared on the forehead at the site of a previous lesion. An intravenous injection of 0.6 g. neoarsphenamine was given on Feb. 13, and by Feb. 14 the temperature had returned to normal, after only a mild reaction to the arsenical. The skin lesion was now fading. He remained afebrile until discharge on Feb. 24, having had a further 0.6 g. of neoarsphenamine on Feb. 21 (mild reaction only).

On March 9 he appeared quite well, but stated that he had been having attacks of paroxysmal tachycardia, especially at night, each lasting about an hour. His pulse was 110.

Second Admission.—On March 14 the patient was readmitted, complaining of pain, stiffness, and swelling in his right arm of four days' duration. The first symptom noticed was tenderness of the muscles, beginning with the right biceps but later spreading to the forearm and shoulder muscles. This was followed shortly by increasing swelling of the muscles, with accompanying pain and stiffness. On examination he did not look ill, but his face was flushed and his skin hot and moist. There was marked brawny swelling of the right forearm and arm, most pronounced in the biceps region. The whole arm was very tender, and movement of the limb caused great pain. There was some tenderness, though very little swelling, of the shoulder muscles. A blood count on March 15 revealed 11,000 leucocytes per c.mm.—neutrophils 8,910, eosinophils 110, basophils 0, lymphocytes 1,430, and monocytes 550; Hb 87%.

Neoarsphenamine, 0.6 g., was given intravenously on March 15 and the temperature rose to 101.2° F., but next day it had fallen to normal and remained so. The swelling of the right arm subsided rapidly; by March 19 it had disappeared, and movements of the whole limb were free and unaccompanied by pain, but there was still a little tenderness on deep pressure over the biceps. Further injections of neoarsphenamine, 0.6 g., were given on March 21, 26, and April 3. With the help of ferrous sulphate, 3 gr. t.i.d., and ascorbic acid, 50 mg. b.d., his haemoglobin had risen to 100% by April 5. He was discharged on April 6, apparently in good order.

He was seen as an out-patient on April 18. In the previous three days there had been some return of myositis in the right biceps, the right quadriceps femoris, and both gastrocnemii. There was not much pain or swelling, and constitutional symptoms were absent. Neoarsphenamine, 0.6 g., was injected intravenously. On April 25 he was seen again and felt quite well. The myositis had disappeared within a day or two of the injection. Another intravenous injection of 0.6 g. neoarsphenamine was given, and a week later (May 2) a final one of 0.6 g. He claimed to be feeling perfectly well.

Third Admission.—On May 22 he was readmitted with pain in the left calf, both thighs, and the left posterior cervical triangle, gradually increasing over the past eight days. Since May 18 he had noticed increasing swelling in the right thigh and the lower part of the left calf. He had had severe headache and had observed tachycardia. On examination he looked rather unwell. Both thighs were tender to palpation, with firm diffuse swelling on the right side. There was a firm tender swelling of the lower end of the left calf. The arms were unaffected. There was also a similar swelling in the left posterior cervical triangle. No other abnormalities were detected. Bood count : Hb, 108% ; leucocytes, 7,000 per c.mm.—neutrophils 5,740, eosinophils 140, basophils 0, lymphocytes 840, monocytes 280.

On this occasion he was treated with penicillin, 15,000 Oxford units three-hourly by intramuscular injection for five days (total, 600,000 units). The temperature on admission was 100.8° F., and it rose next day (after starting penicillin therapy) to 104° F., but within 24 hours it had fallen to normal and remained so. The myositis subsided rapidly, and within four days he was feeling perfectly well.

Discussion

Many of the manifestations of this case conformed more or less to the classical picture and need no further comment. Attention, however, may be drawn to certain less generally recognized features. Thus, the comparative lack of inflammatory changes at the site of the original bite is at variance with the usual description, most authors emphasizing the severity of these changes, as also the attending lymphangitis. It is stated, too, that the inflammation is apt to relapse and remit with the fever, but in the present case, though there was some slight initial inflammation, this soon subsided and did not recur. Splenomegaly is not generally described as occurring in this disease ; it was only transitory in this case and, as a matter of fact, led to some confusion in the diagnosis. But by far the most aberrant and striking feature was the severe and recurrent myositis. Whether this is really a rare accompaniment of the disease I am not in a position to state, but there can be no doubt that observers are unfamiliar with it. Beaumont and Gill (1935) seem to be the first to describe this myositis. In their case the patient was a 9-year-old girl who developed oval tender masses in various muscles, but at no time was the myositis so severe as in my patient on his second admission. Almost as remarkable as the myositis was the rapidity of its subsidence after injection of neoarsphenamine and after treatment with penicillin.

Although it is well known that rat-bite fever, when untreated, is liable to persist for many months, its tendency to relapse after arsenical treatment is much less commonly recognized. Most textbooks state that one to three injections of neoarsphenamine usually suffice. In the present case the inadequacy of three injections, or even of a further seven, requires no emphasis. The decision to use penicillin was based on the report of its success in treatment of experimental infection of mice with *Spirillum minus* (Lourie and Collier, 1943), and with *Spirillum minus* and *Streptobacillus moniliformis* (Heilman and Herrell, 1944 ; quoted by Herrell, Nichols, and Heilman, 1944). It would appear that the present paper is the first record of the clinical use of penicillin in *Spirillum* infections.

Apart from the case of Beaumont and Gill, already mentioned, which was also due to a cat-bite, very few similar cases have been recorded in the literature ; Laverick (1936) and Cole (1936) each described one case, while Yamamoto (1938) recorded two. The last-named was able to isolate spirilla from both patients, and Cole demonstrated the organisms in a guinea-pig after inoculation with a lymph-gland extract from his patient ; the other authors failed to isolate the organisms.

Finally, some comment on the name "rat-bite fever" or "cat-bite fever" seems justifiable. Neither of these names is satisfactory, nor is sodoku, which merely means "rat poison" in Japanese, because these two animals are not the only vectors of the disease, which remains the same, however conveyed. The term "spirillosis" is suggested as being less objectionable than others hitherto proposed.

Summary

A case of so-called rat-bite fever following the bite of a kitten is described. Some aberrant features are discussed, especially the occurrence of severe myositis, repeated relapse after arsenotherapy, and apparent final cure by means of penicillin. A plea for the use of the term "spirillosis" in preference to "rat-bite fever" or "cat-bite fever" is made.

My thanks are due to Dr. H. B. Russell for permission to publish this case.

Medical Memoranda

A Case of Acute Dilatation of the Stomach

I recently met with a case of this rare condition, which occurred spontaneously in a woman aged 62 in apparently good health, actively engaged in domestic work, and which seems to be worthy of notice.

CLINICAL HISTORY

I was visiting the house to see a sick child on March 31, 1944, and saw the woman, who made no complaint regarding her own health. The next day she remarked to her daughter, who was out all day on war work, that she was not feeling well. On April 2 she said that she had vomited during the night. She had some hot milk and tea ; later, feeling better, she came down and had some bread-and-butter and tea. She went to bed at 6.30 p.m., complaining of great thirst. She took some milk, half a siphon of soda-water, some more milk, and a little whisky.

Her condition became so alarming that I was sent for at 9.30 p.m., and found her suffering from profound shock. The extremities were cold and cyanosed, and the pulse was imperceptible at the wrist and in the brachial artery. On auscultation the heart sounds were weak—rate 120, regular. Abdominal palpation at once revealed the diagnosis: the stomach extended down to the pelvis, succussion was easily obtained, there was no visible peristalsis, and the tongue was dry. She complained of great thirst. Hastily I went home two and a half miles for funnel and tube, and the district nurse. I gave rectal saline in the left lateral position with catheter and funnel. This the nurse continued while I passed the stomach-tube, in doing which the patient readily co-operated. Without any difficulty, and with very little retching, I siphoned off 4 pints of liquid gastric contents. The patient was much relieved, and asked for a cup of tea, which I refused. The nurse continued to give rectal saline, and as the patient seemed to be definitely improving I returned home, leaving instructions to the nurse to continue the saline and to give no drink by the mouth. At 3 a.m. I was urgently recalled and found the patient *in articulo mortis*. The nurse had left some hours previously, considering the patient to be well enough to warrant her departure.

Eight hours later I made a partial post-mortem examination. Rigor mortis had set in. On opening the abdomen I found the stomach apparently quite normal in size and position, no sign of injury from stretching being visible on its peritoneal aspect. The musculature was firm and elastic.

COMMENT

I publish this case because the condition is rare and the rapid recovery of the gastric musculature after such extreme dilatation, without apparent injury, seems noteworthy. The cup of tea which she so craved for might have been beneficial, and if intravenous saline had been given, or even the rectal saline persevered with for a longer period, it might have turned the scale and her recovery have ensued.

My previous experience of this condition relates to two post-operative cases, both fatal owing to the diagnosis being made too late, and in neither case was a post-mortem examination carried out. The cause of these post-operative cases has been variously ascribed to the anaesthetic, especially ether; to a kink in the duodenum; to the ileo-colic artery pressing on the duodenum. I believe it is due to the patient having too much drink when propped up in the Trendelenburg position. The stomach is then in an atonic condition and the liquid in it lies heavy, is not absorbed, and therefore does not quench thirst. The patient gets more drink and the stomach sags lower in the abdomen, soon reaching the pelvis; the extreme stretching of the stomach wall causes shock, which is rapidly fatal if not relieved. In neither of my cases was there any evidence of much gas under pressure in the stomach, which has been reported by some observers.

I am not aware, in such cases, of any report of a necropsy in which the stomach wall has been found in its normal position when relieved of the stretching due to the weight of the contents.

Hon. Consulting Surgeon,
Prince of Wales Hospital, Plymouth.

The Initial Treatment of Tropical Ulcer

The purpose of this note is to draw attention to a method of treatment introduced in 1939 by Todd which in my own experience has been extremely effective and which apparently is neither widely known nor much used.

METHOD

On admission the patient undergoes a three-day course of local treatment with a saturated solution of potassium permanganate (approximately 5%), followed by the application of iodoform powder. Without any preliminary cleaning, the ulcer is painted freely with the permanganate solution, which is then allowed to dry as much as possible. In some cases there may be undermined skin at one edge of the ulcer, beneath which a collection of pus forms, and it is then necessary to incise the overhanging skin. This can be done quite adequately and rapidly with scissors and without any anaesthetic. The area thus laid bare should also be treated with the permanganate solution. The whole surface is then dusted lightly with pure iodoform powder and covered with cotton-wool without any intervening gauze. On the second day any loose sloughs are removed with scissors and the whole treatment repeated. The same procedure is followed on the third day. On the fourth day the ulcer is almost invariably clean and covered with healthy granulations, and no sloughs remain. Only in rare instances is it necessary to repeat the treatment more than three times, and I have not yet seen a case which has not been clean and healthy after six treatments. The subsequent treatment can be conducted on any of the familiar lines with antiseptic ointments, occlusive dressings, or skin-grafting.

The advantages claimed for this method of treatment are: (i) It is simple and can be carried out satisfactorily by a native dresser after two or three demonstrations. (ii) It cleans up even the most septic ulcers more rapidly than any other method which I have yet used. (iii) It requires no anaesthetic such as is necessary for curettage or excision. (iv) It is reasonably economical. (v) While of use in all cases of tropical ulcer, it has been found to be of especial value in ulcers in which the tendons are exposed and grossly swollen and which are very slow to respond to other lines of treatment; also in the acute and rapidly spreading type of ulcer. In the latter case the spread is arrested almost immediately.

The method outlined above differs from that originally described only in that pure iodoform powder is used instead of a 20% iodoform dusting powder. I have found the former more effective.

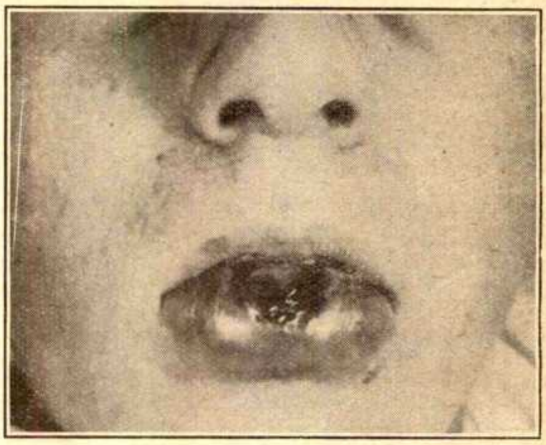
A Case of Rat-bite Fever

The following case appears to be interesting enough to warrant a report.

A youth aged 18 was awakened one night by a rat, which, before he was aware of what was happening, bit his lip twice. There was considerable bleeding at the time, but the wound healed rapidly and he continued in his usual health. Some ten days later the bitten area swelled, became very painful, and signs of general infection appeared, with headache, backache, rigors, and sweating bouts. He was admitted to hospital 18 days after the bite, the above symptoms having continued. On admission the lip was grossly swollen and very painful, with a large black slough marking the site of the bite (see Fig.). There was marked tender enlargement of the lymph nodes in the neck and in both axillae. He appeared ill, had a temperature of 101 to 103°, and was subject to frequent rigors. There was no rash or splenic enlargement. A blood count showed: R.B.C., 4,690,000; haemoglobin, 88%; W.B.C., 7,600, of which 66% were neutrophil polymorphs, 31% lymphocytes, and 3% monocytes. The Wassermann reaction was negative. On these findings a diagnosis of rat-bite fever was made.



Smears from the surface and fluid from aspiration of the lesion showed haemolytic streptococci and *Staph. aureus* only. Lymph-node puncture demonstrated several highly suggestive organisms. Blood was injected into white mice and guinea-pigs. While no growth was obtained from the former, in peritoneal exudate from the latter Dr. H. J. Slade found *Spirillum minus*. A blood culture was negative.

Three paroxysms of fever occurred during his stay. In the third his temperature reached 104.6°, when he was given 0.3 g. of N.A.B. Next morning it had sharply fallen to normal. His lip rapidly healed, the glandular enlargement resolved, and he was discharged well a few days later.

Unusual Termination of Intestinal Obstruction due to a Gall-stone

The following case seems worthy of putting on record on account of its rarity.

On Dec. 20, 1925, I was called to see a woman, 60 years of age, with a history of intestinal obstruction for 8 days. The onset was heralded by pain in abdomen and repeated vomiting, and for about 5 days no nourishment of any kind was retained. The bowels refused to move, and repeated enemas produced no result. The vomiting and pain then ceased and sips of water were retained, but the bowels remained costive and no wind was passed. On examination the abdomen was not much distended, no tenderness was elicited, the pulse was good and not quickened, the tongue not too dry, and thirst, thanks to the sips of water, not marked. She was a fat woman, in comfortable circumstances, living a sedentary life.

She had undergone vaginal hysterectomy in 1920, and had a recto-vaginal fistula. There was no history of colic or jaundice. The woman stated that she had never any trouble with digestion and always fed well.

She was admitted into hospital and a sigmoidoscope passed to the fullest extent. A faint click was felt and heard and a stone was seen. The sigmoidoscope was withdrawn, 1/2 c.cm. of pituitrin injected, and an enema given. A few minutes later the bowels moved, bringing with the faeces a large single stone, the shape of a gall-bladder very much enlarged. It was of light weight and speckled. Presumably it was formed without infection, and left the gall-bladder through a perforation into the bowel without causing any signs and symptoms felt by the patient. This, however, is not unusual with these single stones. The woman is alive and active for her age.

Reviews

SEROLOGICAL REACTIONS, AND THE FORMATION OF ANTIBODIES

The Specificity of Serological Reactions. By Karl Landsteiner, M.D. Revised Edition. With a chapter on Molecular Structure and Intermolecular Forces by L. Pauling. (Pp. 310. $5.00, or 28s.) Massachusetts: Harvard University Press; London: Oxford University Press.

Immuno-Catalysis. By M. G. Sevag, M.D. With preface by Stuart Mudd, M.D. (Pp. 272. $4.50, or 25s.) Springfield and Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox. 1945.

The first edition of Dr. Landsteiner's book was published in 1936; the present edition was completed textually by him before his death in 1943, and has been left as it was except for minor changes in the structure of sentences. The new edition follows the general plan of the first, but two new chapters have been added: one on antigen-antibody reactions and one on molecular structure and intermolecular forces, by Dr. Linus Pauling. With these additions the book gives a complete account of the theoretical aspects of serological reactions brought up to 1943. As before, the specificity of proteins, modified by methods such as treatment with iodine or nitric acid, is dealt with in Chapter II, and the specificity of artificially conjugated antigens, such as those made by coupling proteins with diazonium compounds, is dealt with in Chapter V. This separation is somewhat artificial, but it brings out the relative importance of the two methods in the development of the science of immunology. By the second it was possible to attach to protein molecules a large variety of determinant groups. The wide range of examples given in Chapter V proves how valuable this method has been in showing the influence of composition and structure on specificity. But what was more important was that the method made it possible to demonstrate by the inhibition reaction the specific combination of determinant group and antibody. It looked as though Ehrlich's side-chains had been demonstrated objectively. It may no longer be possible to regard antibodies as broken-off "side-chains," as pointed out in the chapter on the nature and specificity of antibodies. But the modern theories of their formation discussed there are not so very different from that of Ehrlich.

In a way, however, the results obtained with these conjugated antigens gave a false outlook. For in the earlier experiments of this type specificity was determined mainly by the presence of certain characteristic chemical groups; the most effective antigen contained arsenic. But, as is clear in the case of the polysaccharides, specificity of natural antigens depends on the spatial arrangement of a limited number of common groups and the modification of their electronic structure brought about by their environment; Ehrlich's conception of side-chains must be modified. The difference between Ehrlich's and Bordet's theories has largely disappeared. Antigen-antibody reactions can be considered to be a matter of physical chemistry. But Ehrlich wins, for he rightly insisted that the essential stage of these reactions is the specific combination—*Corpora non agunt nisi fixata.* It would be interesting to meet the spirit of Ehrlich and find out whether he thought of those interlocking diagrams of his as representations of actual structures in space or merely as symbols of chemical composition.

As our knowledge of the relation of specificity to structure extends the reactions and cross-reactions of non-protein antigens (which are dealt with, none too clearly, in Chapter VI) and of proteins should become examples of a general theory. It is not surprising that any cell contains several substances which can themselves provoke the formation of antibodies or co-operate in the forming of antibodies. Cross-reactions between two types of cell may be due to the presence of the same antigen in both or to a sufficiently close resemblance between two different substances which they contain. Some of the reactions and cross-reactions of cells—for example, the iso-agglutinins—will continue to affect us intimately; others will find practical application in diagnosis. But as a whole the majority of those described in Chapters II and III and the multitude of others that may be worked out should in time become examples of the relation of specificity to structure and be recorded in tables or by a card system of practical value, like time-tables, but not matter for reading.

Chapter VII gives an indication of the way in which the theories of protein structure and behaviour are beginning to offer explanations of the antigen-antibody reactions, given the specific combination of antigen and antibody which is the essential. The last chapter, by Dr. Pauling, is the clearest exposition yet made of the nature of the intermolecular forces on which this specific combination depends. According to the theories current to-day the antigen acts as a kind of pattern on which the amino-acids of globulin molecules in process of synthesis are assembled or those of existing molecules rearranged. But these theories leave unsolved one aspect of the problem, which has become more puzzling since the work of Schoenheimer has shown that proteins in the body are not stable but in a continuous state of flux. How is it that the pattern can survive and keep up the formation of antibodies for years after its injection?

Dr. Sevag's book also deals with the formation of antibodies. His main thesis is that antigens act as catalysts, with antibodies as end-products of the process, and that the reactions of antibodies with antigens are comparable to the inhibition of enzyme actions by the end-products. This analogy may be justifiable, since both enzyme and immunity reaction depend on specific combination. But it is not an advance; the theories of Breinl and Haurowitz, of Mudd and of Pauling, quoted by Dr. Sevag, take us further towards understanding the formation of antibodies. The book contains a large amount of information about the relation of specificity to structure; the physical chemistry of antibodies and immunity to enzymes. Some of this is rather misleading. The fact that Block considered that the molecular ratios of four amino-acids are the same in the haemoglobin of horse, cattle, sheep, and dog, although these haemoglobins differ immunologically, is advanced as an objection to Bergmann's theory of protein structure; but the immunological differences may be due to differences in the ratios of the other amino-acids. And on page 221 it is stated that "there is practically no difference in the rates of sedimentation of immune and normal globulins ($S = 6.8$ to 7.2×10^{-13})"; while on page 12 Dr. Sevag quotes Kabat's figure of 18×10^{-13}) for the sedimentation constant of antibody in horse antipneumococcus serum.

ACUTE INTESTINAL OBSTRUCTION

The Treatment of Acute Intestinal Obstruction. By Judson T. Chesterman, F.R.C.S. (Pp. 116; illustrated. 10s. 6d.) London: J. and A. Churchill. 1945.

Since the appearance of Wangensteen's book on intestinal obstruction, which introduced some novel ideas on the handling of such cases by intubation of the intestine, there has been a revival of interest in the subject. A small book by Mr. Judson Chesterman has just been published which puts the whole subject very succinctly and forms an excellent introduction to the study of the condition. The author has himself carried out a considerable amount of experimental work on various aspects of intestinal obstruction, and his results are incorporated in the conclusions which he reaches.

Two of the chapters we found of particular interest: the first dealing with the factors which so frequently produce serious, and even fatal, symptoms after the release of the obstruction—a phenomenon which has worried surgeons since surgical treatment was first undertaken. The second special interest was in the chapter dealing with the radiographic diagnosis of acute intestinal obstruction—a method which is rapidly becoming of great importance. This section is illustrated by some carefully chosen and well-produced radiographs. There is also a good description of the suction treatment of obstruction, which correctly gives due weight to the difficulties and contra-indications of the method. In the rest of the book we noted with approval the author's preference for light spinal anaesthesia in the "good-risk patient," and also his advocacy of Lake's tubes in performing Paul's operation on elderly patients, thus doing away with the need for multiple-stage operations. There is a good chapter, too, on neurogenic ileus, both of the paralytic and of the spastic types.

The only criticism we have to offer is that the need for great condensation has led the author on occasions into a rather ambiguous type of composition which requires very careful interpretation before its real meaning is made clear. On the whole, however, the book gives a very favourable impression and can be strongly recommended.

RELIEF OF TENSION

Release from Nervous Tension. By David Harold Fink, M.D. Edited, and with an introduction, by Harry Roberts. (Pp. 246. 8s. 6d.) London: George Allen and Unwin.

As Dr. Harry Roberts says in his foreword, the chapter headings of this book are most intriguing: "Meet the Interbrain," "Let go—a Little More," "Treat Yourself to a Fresh Start." The author seeks to impress upon the public the need for relaxation, in colloquial and sometimes in facetious terms. He does not believe in human instincts and declares with a fine confidence that they do not exist, but he believes in conflict, though not much in unconscious processes. He does stress the fact, however, that you can't have mental tension without bodily tension, and that the secret of happiness is relaxation, both bodily and mental. He may possibly oversimplify the way in which such complete relief of tension may be achieved, but there is no doubt that people can do a lot for themselves in this way.

The medical profession can hardly look upon this book as a serious contribution to science, but it may be very useful to some of their patients. The following extract on massage may give some idea of its style.

> "Being massaged is another passive play activity that many people find most soothing. This is as infantile a pleasure as sun bathing, and as fundamentally human, perhaps subhuman, because even a cat likes to be stroked. Massage is scientific fondling. My only objection to massage is the expense, but a gentle massage by an expert is well worth the money. Twenty minutes of brisk rubbing and patting, followed by five minutes of gentle stroking, is good clean fun and fine for the nerves."

Bearing in mind that he is talking about the treatment of the psychoneurotic, he is probably not far wrong.

Notes on Books

Aids to Tuberculosis for Nurses, by Dr. L. E. HOUGHTON and Mr. T. HOLMES SELLORS, is published at 4s. by Baillière, Tindall and Cox. This excellent little book, suitable for the apron pocket, will enable nurses to find their way in the new tuberculosis nursing. Nothing in medical organization is more remarkable than the change that has come over our sanatoria during the last ten years. Active surgical treatment, psychology, and rehabilitation now fill the nurses' thoughts. Her patients are under care for many months at a time, and she must be well equipped to deal with their problems. This book gives a complete summary of tuberculosis, its pathology and treatment, with some excellent illustrations, *x*-ray pictures, and instrument diagrams. The nurse who masters its contents will be well equipped for examination. We should like to be sure that it would be read with equal attention by some senior members of the nursing profession, including those whose own sanatorium experience was very different from the modern outlook described in this book.

The 1944 Year Book of Industrial and Orthopedic Surgery, edited by Charles F. Painter, M.D., is published in Chicago by the Year Book Publishers, and in London by H. K. Lewis and Co. at 18s. The editor is again to be congratulated on having collected in concise and readable form short abstracts from current articles on a wide range of orthopaedic and fracture subjects. The illustrations are numerous and beautifully reproduced. This annual, like its predecessors in former years, should find a ready market amongst orthopaedic surgeons. It can be used as a bedside book, and one can "dip" into it at random and always find something interesting, often with constructive comment by the editor. Subjects which are especially topical are a series of abstracts on the Kenny method of treatment of poliomyelitis; intervertebral disk injuries; the scalenus anticus syndrome; primary bone-grafting for os calcis fractures; and many other topics. The book concludes with a section of about fifty pages dealing with industrial medicine and surgery. In the opinion of the reviewer this would be better omitted and, if necessary, made a separate volume in the series of Year Books.

No. 2 of *Notes of the Czechoslovak Medical Association in Great Britain* (published by the Czechoslovak Research Institute, Fursecroft, George Street, W.1, at 3s. 6d.) opens with a valedictory note headed "1938 to 1945." This editorial includes the following passage: "We salute our liberated countrymen and our gallant Allies! Thus our exile ends, but before we leave for our homes we want to express our affection and gratitude to the British friends with whom we have lived and worked during the course of the gigantic struggle. This spirit will always have our admiration." The Editor of the *Notes*, in saying "au revoir" to friends in Britain, hopes that the collaboration between medical men and women in our two countries is not ending but only passing into another stage.

The report of the Scientific Advisory Board for the year 1944 has been issued under the authority of the Governing Body of the Indian Research Fund Association. Copies, price 1 rupee, may be had from the Secretary of the Association, at the Imperial Secretariat, New Delhi, India. The report runs to 188 pages, and the longest sections are on nutrition, on cholera, on leprosy, on malaria, and on plague. There are also reports of inquiries into indigenous drugs and of a number of miscellaneous researches.

The Civilian Relief Overseas Section of the British Red Cross Society and Order of St. John has issued from 5, Lowndes Street, London, S.W.1, a little *Medical and Nursing Vocabulary in English and Greek* compiled by Miss HESTER VINEY and revised by Dr. N. C. Constantoulis, who writes a brief introduction. The user of the booklet must be able to read Greek characters. Words and phrases have been carefully chosen from those in most frequent use by the majority of Greek people to-day.

Preparations and Appliances

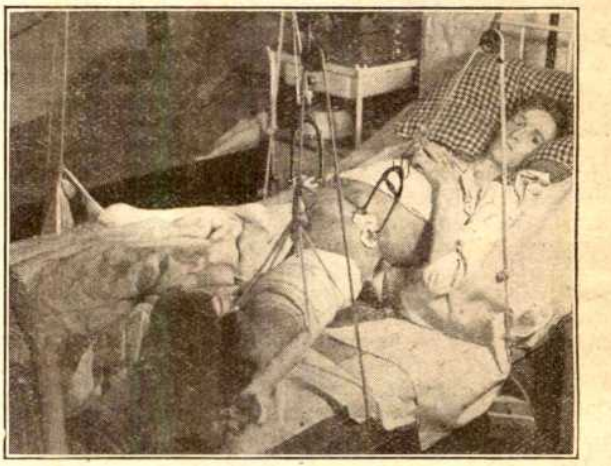
APPARATUS FOR TREATING BED-SORES

Capt. J. F. NEIL, R.A.M.C., writes:

While inspecting a German marine lazarette recently I found in use an unusual method of treating a bad bed-sore, in which the cardinal requirement of treatment (i.e., the avoidance of prolonged pressure on any part) is met by suspending the patient from his anterior superior iliac spines. I thought an account of the case and some details of treatment would be of interest.

Case Report (July 26, 1945).—The patient, a young German soldier, was wounded on May 4, 1945, by a shell fragment in the left knee. The joint became infected and a pyarthrosis developed. He became very toxic and anaemic, and about four weeks ago developed a bed-sore in the sacral region. This failed to respond to the usual treatment, using air-cushions and so on; frequent changing of his position was difficult because his left leg had to be splinted. The patient now has a deep bed-sore involving the medial half of both buttocks, spreading up over both ilio-lumbar ligaments and leaving the sacrum exposed in the centre of the lesion.

Treatment.—Ten days ago the surgeon put him up in the apparatus to be described. A Kirschner wire was put through each anterior superior iliac spine under local analgesia and fitted with the usual stirrup. Both legs were put on well-padded Kramer wire back-splints. He was then suspended from a Balkan frame by counter-weighted cords passing from the two stirrups and the two splints, over pulleys. His head and shoulders were rested on an air-cushion. He now lies suspended about 3 in. from the bed. The main weight of the trunk is taken by the two wires, and the splints carry only the weight of the legs, his head and shoulders alone undergoing any pressure. The photograph shows all the details of the arrangement. After a little initial discomfort he is now very comfortable, and his only complaint is that he is not able to move about much. The sore is improving and nursing is easy.



Comment.—The surgeons say they have used this method in several cases, and find that six weeks is about the maximum time a man can be left in this position without trouble. They have had one man treated for eight weeks with good results. Sometimes they use wires through the tibial tuberosity as well, especially if there are bed-sores on the legs.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 22 1945

FOOD CONDITIONS IN POLAND

During the last three years opinion in Britain has swung between exaggeration and extreme underestimation of the degree of scarcity of food in occupied Europe. The result of this uncertainty has been disastrous, as there has been no steady demand for adequate plans for dealing with the crisis that inevitably arose as the fighting ended. The detailed report on food conditions in occupied Poland, published by the Polish Ministry of Labour and Social Welfare,[1] is still worth attention as example of the degree of privation in a large area before the final disorganization began.

After the German occupation all Western Poland and a large part of Central Poland were incorporated into the Reich, while the central and southern provinces formed the General Government. In the incorporated provinces Polish farmers were expropriated and hundreds of thousands of German colonists settled on the land. These provinces were under strict control as the granary of the Reich; but, in spite of the distribution of fertilizers, agricultural machinery, and seeds, and the improvement of the livestock, food production fell below the pre-war level. In the General Government area agricultural production deteriorated still more owing to loss of capital goods and livestock and shortage of fertilizers and draught animals. Before the war Poland exported well under 10% of the food produced, and maintained a mediocre standard of living on the remainder. After occupation the Nazis' requisitions were over 10% of the produce, in spite of lowered production. The inevitable scarcity was worst in the General Government area, for before the war this area had not been self-supporting but had imported food; after occupation it had to meet Nazi requisitions and feed a population swollen by people deported from Western Poland as well as the enemy garrison. There were therefore four ration scales—one for Germans (very similar to that in the Reich); one for Poles in the incorporated areas; one for Poles in the General Government; and one for Jews. The rations for Jews may be dismissed as an extermination ration. In the incorporated area the Poles were allowed about half as much meat, fats, and cheese as the Germans were; in 1942 rations of meat (100 g. per week) and of fats (50 g. per week) for Poles in the General Government were about 30% lower, and the sugar ration (70 g. per week) 70% lower, than in the incorporated area. At the end of 1944 meat and sugar rations had not risen and no fats were allowed to the normal consumer. As no extra cereals or potatoes were allowed, in order to make up for the deficit of animal products, the total of calories provided by the rations in the incorporated area were under 1,500 a day for an ordinary adult and about 1,200 in the General Government; and these rations could not always be obtained. Extra rations were allowed to heavy workers, and at the end of 1943 to their families as well. But even very heavy workers got under 2,000 calories a day. Only those engaged in work of military importance got these extra rations; the vast majority of Poles were rationed as normal consumers. The rations for young children supplied enough calories, though they were allowed skimmed milk only, and in 1943 this allowance ceased at 3 years in the General Government and at 6 in the occupied area. But the calories supplied did not rise with age, and amounted to no more than 758 per day at 10 to 14 years—about one-third of the League of Nations standard. The total protein at this age was 24 g., of which 2.6 g. was animal protein, and the calcium 91 mg. per day.

Throughout the greater part of occupied Europe foodstuffs that supplied over 90% of the day's calories have been rationed, and the official rations have supplied well under 2,000 calories per head per day. This has been known well enough; the uncertainty which has led to wide differences and fluctuations of opinion has been on the possibility of supplementing this scanty fare with unrationed food or by irregular means. It will never be possible to dispose of this uncertainty, because all data about production are untrustworthy, and conditions varied from one place to another and from one family to another. But, as the amounts of food requisitioned from Poland were about double the amounts exported before the war, food must have been scarce, even if production had not fallen below the pre-war level. Until scarcity of food becomes extreme the agricultural population invariably fare better than townspeople; it is probable that the actual consumption by peasants in Poland was more than the 2,000 calories a day calculated from statistics of production. About 70% of Poland's population is classed as "rural," but a large proportion of these are not engaged in producing food—lumbermen, for example—and may have been little better off than the people in the towns.

It is often claimed that people in occupied Europe made up the deficiencies in their official calories through the black market or by eating very large amounts of vegetables. But in an area in which food actually is scarce the black market can only aggravate the privation by causing unequal distribution. Prices in the black market in Poland were so high that the greater part of the population could not buy in it after their stock of disposable property was exhausted; in fact a good deal of the "black" trade was in coupons for meat, which the poorer people sold in return for bread or potato coupons; this trade altered the distribution of calories but did not increase the average per head. As Durig in Vienna pointed out, it was not possible to eat or even to cook enough vegetables (excluding potatoes) to make up a serious deficit in calories, even if enough land could be devoted to producing these quantities. In Warsaw a large number of open spaces were taken for allotments of about 1/12 acre; half were to be sown with potatoes. With a fair yield one of these might provide some 250,000 calories a year, or under 200 calories a day to each of a family of four. But owing to the limited amount of free space in towns few could benefit from the allotments.

[1] *Food Conditions in Occupied Poland.* Analysis of the German Food-rationing System in Poland. By Leon Dmochowski, M.D. Published by the Polish Ministry of Labour and Social Welfare in 1944. London.

There can be no doubt of the serious undernutrition of the Poles, especially of children, during the period covered by this report. The final stages of the war—bombing and blowing up of railways, appropriation of the remaining transport by the military, consumption of seed and dislocation of harvest and sowing—all have accelerated the scarcity of food in Europe. In the Polish area the expulsion of the German settlers and the flight of Germans from the area east of the Oder will again set farming back. At the end of July the U.S. Office of War Information reported: "... Thousands of people will starve and freeze to death in Europe this winter unless help can be rushed from outside. Tens of thousands of others will be hungry and cold. They will be jobless. If no help were to be forthcoming from the outside, they would almost certainly riot, because the authorities could not enable them to get the vital necessities of life. Without this help they would succumb to disease, because their weakened bodies cannot stand up against further hardship. The economy of Europe has been running downhill fast. Production is already at unbearably low levels. Faced with a continued lack of food and incentive goods for workers, transportation for materials and, chiefly, lack of coal, it would continue to fall steadily. . . ."

Newspaper reports of the terrible plight of the Germans displaced by the Poles west beyond the Oder show that the goddess Nemesis is as remorseless as ever.

INFANT MORTALITY AND SOCIAL CONDITIONS

The causes of infant mortality and the methods by which it may be reduced have been medico-sociological problems of the first importance for several decades. Considerable progress has been made towards a solution, and the rate is now only one-third of that at the beginning of the present century. The continuous fall in the birth rate has made it even more imperative to reduce unnecessary wastage of infant lives, and it is generally acknowledged that a further reduction is possible, probably to one-half of the present level. Infant mortality exhibits associations similar to those of the general death rate—e.g., a progression with urbanization and with the social-class classification of the Registrar-General; but the former is more sensitive to adverse conditions than the latter, and this has led to its adoption as an index of the relative social and economic well-being of a community. Infant mortality has given a good approximation when used as a relative measure of these conditions, though it would be, perhaps, a bold person who gave unqualified support to Hersch's[1] recent contention that it is the best single index of the degree of civilization attained by a country. He stated that a high infant mortality shows a condition of poverty and inferiority, while a low mortality reflects the best hygienic conditions, the greatest advances in medicine, bacteriology, chemistry, public education, and intellectual progress. It has been suggested by Mitra[2] that infant mortality is less sensitive to social conditions than it was 20 years earlier, owing to the large decrease in the rate itself and to an improvement in general living conditions; but it is still highly correlated with social and environmental conditions.

The latest paper on this subject is by Woolf and Waterhouse,[3] who have used the infant mortality during 1928–38 in the county boroughs to assess social influences. Their finding that economic conditions are inversely related to infant mortality is well known and generally accepted, but their conclusions are not so well founded. They were, apparently, so enamoured of their lengthy arithmetical processes that they overlooked the first lesson in statistics—i.e., that correlation is not necessarily causation—and they conclude that "23.1 is the infant mortality that would prevail if our five poverty symptoms would be eliminated." This rate is much below 32.7, the rate for Social Class I, and we may safely assume that poverty was not a factor here. The many factors associated with infant mortality are highly interrelated, and one cannot assess their relative importance; but the authors have allocated one-sixth of the excess mortality to overcrowding, one-quarter to low-paid occupations, one-fifth to unemployment, and one-eighth to the industrial employment of women. Apparently public health workers and authorities have deluded themselves for years by assuming that infant mortality was influenced by complex factors and that medical science and improved mothercraft could affect this rate. But perhaps they were not so largely mistaken, since in 1943 and 1944, when enemy action had made the housing position worse and the employment of women in industry was on a higher scale than ever before, the figures for infant mortality were 49 and 46, the lowest values ever recorded in England and Wales. Between 1911 and 1931 the infant mortality of Social Class V was halved, due, the authors state, to improvement in environment. The mortality of Social Classes I to IV also declined at approximately the same rate, and it seems more reasonable to suggest that a factor independent of social class was responsible for a large proportion of this improvement. That social and economic conditions are of great importance in determining the size of the infant mortality has been established beyond doubt, but curious anomalies exist. For instance, Social Class II in the regions of Wales I and North I had in 1930–2 a larger infant mortality than any class in the South-East (excluding London) with the exception of Class V, which cannot be explained by differences in economic conditions.

Woolf and Waterhouse fail to appreciate the paucity of the data which the pioneer writers on this subject had at their disposal. The indices the earlier writers used were the best available, and they fully realized their imperfections. The use of the proportion of female domestic servants in the female population as an index of the residential nature of a district is not so foolish as the authors would have us believe. They state that "high proportions of domestic servants are found not only in well-to-do areas but also in those poverty-struck places like Newcastle-upon-Tyne and Merthyr Tydfil." In fact the percentage in these towns was only about one-third of that in Eastbourne and Bournemouth. Women in highly industrialized areas, where no opportunities exist for female labour, are not forced by circumstance into domestic service; they migrate, as a comparison of sex ratios would demonstrate. Among other statements that are open to question is the assertion that the use of the correlation coefficient is not valid unless the distribution is normal. The correlation coefficient involves no assumption of normality or indeed of any other type of distribution; it is a measure of linear relationship, being the coefficient of the straight line fitted by the method of least squares when the variables are measured in terms of their standard deviations. In several recent articles dealing with environmental indices the uninformed reader is likely to form the impression that the social-class classification of the Registrar-General is a caste system. This is not wholly true, since there is considerable migration from class to class. At ages 20 to 24 the proportion in Classes I and II in 1930–2 was 74 per thousand; this proportion was trebled by late middle life by promotions from the lower classes. This might be expected, for responsible positions are not generally obtained by young men. The constitution of the social classes varies much between the various regions of the country, and the correlation of general mortality and social-class classification is a feature of the life of large towns; the relationship is less clearly shown by the small towns, and not at all by the rural districts. No one can feel satisfied until infant mortality in this country is down to an irreducible level, but in seeking for the causative factors that may be attacked strict objectivity is needed.

POTASSIUM THIOCYANATE POISONING

The use of potassium thiocyanate for the treatment of hypertension has continued now for many years, though it has not been widespread. Many physicians have remained doubtful of the value of this form of treatment, and others have regarded it as dangerous. Barker[1] in 1936 recommended that when potassium thiocyanate was given the amount in the blood should be determined, so that it could be ascertained that the amount was not too low to be effective or too high to be dangerous. Barker's paper gave an impetus to the use of thiocyanates, for it provided a means of avoiding toxic effects. No certain basis has been established for the mode of action of thiocyanates in lowering blood pressure, though it is known that thiocyanates, as does thiouracil, act on the thyroid gland and so depress the output of thyroid hormone. Since thyroidectomy has been found to be of value in the treatment of angina, it may well be that thiocyanates lower blood pressure by their action on the thyroid gland.

A number of deaths have resulted from the therapeutic use of thiocyanates, and del Solar, Dussaillant, Brodsky, and Rodriguez[2] have now brought the total to seven. Their patient was one among 73 to whom they gave the drug, and they ascribe his death to accidental overdosing, due to the patient's measuring his medicine with a dropper of which he had broken the tip. As a result he took, for 22 days, 0.9 gramme daily instead of 0.6 gramme. At the end of this time the blood contained only 2.5 mg. per 100 c.cm. and the intended dose was raised from 0.6 to 0.9 gramme—but in fact from 0.9 to 1.35 grammes. After six days he developed toxic symptoms, and the administration of thiocyanate was stopped; in spite of this the patient died 16 days later. The symptoms began with clonic contractures of the upper extremities, followed by some delirium and motor incoordination. After four days coma supervened, with tachycardia and Cheyne-Stokes respiration; the presence of a spastic right hemiparesis led to a diagnosis of a toxic encephalopathy. After a temporary recovery of consciousness, when the blood pressure had fallen to 130/90, coma reappeared and the patient died. Post mortem, an area of very recent haemorrhagic encephalomalacia was found in the left occipital lobe. Large amounts (20 to 30 mg. per 100 g.) of thiocyanate were found in the brain, heart, kidney, liver, lung, and muscle. The authors consider that the danger of a toxic encephalopathy may prove to be a contraindication to the use of thiocyanate in elderly persons, since in five other cases similar findings have been recorded.

ACTION OF MAGNESIUM ON THE UTERUS

The magnesium ion has been shown to possess a powerful depressant effect on all nervous and muscular functions. This is not seen when magnesium compounds are given by the alimentary canal, since the magnesium ion is not absorbed in sufficient amount unless massive doses are given. Magnesium by injection depresses first respiration and then cardiovascular function, with a fall of blood pressure and vasodilatation. It also has a curare-like action on muscle, operating, it is believed, on the neuromuscular junction. Magnesium could, in theory, be employed as an anaesthetic, but its use is limited by the fact that the effective dose is dangerously close to the fatal dose.

Abarbanel[1] has shown that the magnesium ion reduces the spasm of tetanic contraction of the human gravid uterus—an effect also observed in animals by several workers, in particular by S. R. M. Reynolds,[2] who demonstrated that magnesium chloride inhibited the uterine contraction caused by calcium and prevented a further response to it. In small amounts magnesium has no effect on spontaneous, rhythmic uterine contractions. Van Dyke and Hastings[3] had previously shown that magnesium ions, in an optimum concentration, inhibit the response of the guinea-pig's uterus to posterior pituitary extracts. In a case of sustained tetanic uterine contraction with severe abdominal pain, Abarbanel injected 10 c.cm. of a 20% solution of magnesium sulphate intravenously; the tetany and pain disappeared, and the uterus contracted spontaneously and rhythmically. Further work on these lines showed that magnesium abolishes uterine tetany induced by oxytocic drugs, and also prevents the onset of tetany if given a few minutes before or after the injection of an oxytocic drug. Various clinical applications of magnesium are suggested—for example, in the relief of tetanic contraction from oxytocic drugs given to induce labour or during the third stage of labour, in cases of Bandl's ring and abruptio placentae, and as magnesium gluconate by mouth for relief of after-pains. Injection of magnesium alleviates the pain of spasmodic dysmenorrhoea, and taken by mouth daily for two weeks before the onset of menstruation gives considerable relief.

This enthusiastic report must be received with the greatest caution. Abarbanel minimizes the danger of parenteral injection of magnesium salts: severe and sometimes fatal respiratory and vasomotor collapse may occur after their administration. Calcium, the antidote, should always be at hand, but even the prompt administration by the intravenous route of calcium chloride or gluconate may not save the patient's life. Severe sloughing with abscess formation has followed the intramuscular injection of magnesium. The use of magnesium salts in the manner suggested can hardly become a part of obstetric practice until further work has confirmed the value—and, above all, the *safety*—of this method of treatment.

AN EDUCATION "WHEREABOUTS"

Owing largely to the circumstances of its historical development, the educational structure of England and Wales is a confusing labyrinth. How many citizens who pay the education rate could pass an examination in the system with credit? It is a dull subject largely because of the number of imperfectly understood and ponderous terms which attach to it. How many could say what is an "excepted district," or what is the "agreed syllabus" or the "dual system," or in what respect a "controlled school" differs from a "voluntary school," or an "aided school" from an "assisted school"? Some terms, fortunately, such as "provided" and "non-provided," have gone into obsolescence with the passing of the Act of 1944. The Ministry of Education has done a real service in issuing a *Guide to the Educational System of England and Wales* (H.M. Stationery Office, 1s.)—60 pages of clear, informative writing, unencumbered by references to sections of Acts or to authorities. It shows the general reader how the new educational reforms will operate, and gives details of those aspects of the old system which will still continue, as scaffolding, while the new building goes up. Every stage of education is described from the nursery school to the university, though the university remains independent of the Ministry of Education, receiving its grants from the Treasury. The way in which the Ministry co-operates with local authorities and the duties of local authorities themselves are sufficiently described. There is also a brief history of English education, with the landmarks of 1870, which saw the beginning of the board school; of 1902, when the council school was created; of 1918 with the Fisher Act; and finally the comprehensive changes brought about by the Butler Act of 1944.

There is a short section on the school medical service, describing how it has been widened under the new Act to cover all children in primary and secondary schools maintained by local education authorities and also, when they are established, in county colleges (institutions provided by local education authorities and attended part-time on a compulsory basis by young people under 18). It is added that the setting up of a comprehensive national health service will eventually ensure that all forms of treatment which school-children require will be available to them through that service, and when that stage is reached it will no longer be necessary for local education authorities to provide treatment generally. Their functions will shrink again to medical inspection and to ensuring that children and parents are properly advised and encouraged to seek, through the new health channels, any treatment the children may need.

THE HOMELESS CHILD

The care of children who have been removed from their own homes is a major problem in this country and is likely to be a very much greater one on the Continent. Before anyone, however, can deal with children's problems he needs to know something about child development. Even the simplest knowledge cannot be taken for granted in a would-be helper. The Provisional National Council for Mental Health has found it necessary to publish a very simple and useful memorandum setting out the A B C of what a child needs.[1] For satisfactory development of the whole personality, it appears, a child depends on a combination of good relationships and individual achievement. Continuity of care by a loving adult is particularly necessary in the earlier years. Where there is a good relationship he absorbs the adult's standards within himself and is able to progress towards self-discipline. Opportunities for interests and activities and the fostering of personal responsibility are necessary for the wise training of children. Training a child for a job is of little value without a social adjustment that makes him spontaneously wish to play his part as a member of the community. The fundamental needs of the child are emotional. In the normal family emotional needs are satisfied with little or no thought. Where an unrelated person has to care for the child a special understanding is required. This is the least that should be demanded, not a fanciful addition to training. The most obvious lack of the homeless child is close personal relations with someone in place of a parent. The next lack, related to it, is a set of standards of his own, a satisfactory attitude to work, and a sense of social responsibility. Placing in a foster-home may and should provide the individual care required and offer a substitute family setting, but its value will be lost if the child is not fully assimilated into the home. Once a child is well placed it is disastrous to move him again. His power to adapt to change throughout his whole life afterwards may be devastated by a rooted feeling of insecurity. Every precaution should be taken to find the right foster-home for the child and to make the necessary adjustments. There is danger to the child's real welfare in placing him in a large group, as may happen in a children's home. Every effort should be made to organize within a large institution groups small enough to allow a personal relationship between each child and a member of the staff. Provision must also be made for individual freedom and responsibility by increasing contacts with the outside world, such as tea with school friends, shopping, and spontaneously joining clubs. The group should contain children of different ages, so that the younger may receive help and the older develop self-confidence. Boys and girls should be brought up in the same homes, and the staff should include men and women. A married couple can give the other members of the staff, as well as the children, a homely atmosphere. Adolescents may need to be separated from younger children when they begin to develop adult interests, and it may be advisable to separate the sexes because of their different needs. Boys and girls should, however, have the opportunity of sharing their activities at all ages. A good foster-home may solve the problem of a maladjusted or physically handicapped child. For difficult children it is better to classify homes according to the facilities they offer and the type of superintendent in charge, rather than by the cases admitted. A child with disorder of behaviour or personality should have his problem thoroughly investigated, and for this purpose it may be necessary to set up a reception centre, which would also be used for children who have broken down after being placed.

Dr. John Parkinson will give the Hunterian Oration before the Royal College of Physicians of London on St. Luke's Day, Thursday, Oct. 18, at 3 o'clock. His subject is "Rheumatic Fever and Heart Disease."

The Committee of Privy Council for Medical Research has appointed Dr. Patrick Alfred Buxton, F.R.S. (professor of medical entomology in the University of London), and Sir Alexander Fleming, F.R.S. (professor of bacteriology in the University of London), to be members of the Medical Research Council from Oct. 1, 1945.

HOUSING AND HEALTH*

BY

H. NELSON, M.D., D.P.H., D.T.M.

Lieut.-Col., S.A.M.C.; M.O.H. Pretoria

There is overwhelming evidence that when people live in slum districts they develop higher sickness and death rates than when they are better situated. Vital statistics have proved this in the very many field surveys which have from time to time been undertaken in other countries. No such figures have yet been recorded among Europeans in South Africa. We do not even possess correct vital statistics for all non-Europeans, because native notifications are inaccurate. We *have*, however, correct figures for Europeans and coloured people. As the coloureds as a whole are much poorer than Europeans, these statistics, though not comparable in every respect, do afford a means of comparing health conditions of the poor and the better-off in South Africa. If figures for Europeans and natives had been available the contrast would have been still greater, because the natives as a whole are still poorer than the coloureds, and from the few figures which we have—inaccurate as they are—there is little doubt that health conditions are much worse among natives.

Some Statistical Evidence

Let us analyse some of the figures for Europeans and coloureds for the year 1938. This year is chosen for no other reason than because it was the year before the war.

The general death rate, which reflects the chances of survival from all causes of death, was 9.48 per 1,000 for Europeans and 23.74 for coloureds. The infant mortality rate—that is, the number of infants who die in the first year of their lives per 1,000 live births—is a very good indication of existing health conditions. This figure for Europeans was 51.69 and for coloureds 165.7 Tuberculosis, a disease directly associated with poverty and bad housing, had a death rate per 100,000 of 38.83 among Europeans and 506.4 among Cape coloureds. Similar conditions are found in all vital statistics of these two sections in South Africa.

From other countries we have the same evidence of higher sickness and death rates among the poor.

In 1928 the infant mortality figures in eight different cities in the U.S.A. were studied and analysed and published in the Public Health Reports of the U.S.A. It was found, on the basis of 23,000 records of birth, that:

(1) The infant mortality rates decreased in direct proportion to the amount of money which the population paid in rent. For example,

Rentals under 15 dollars, infant mortality rate	65
„ 15–20 „ „ „ „	43
„ 20–25 „ „ „ „	45
„ 25–30 „ „ „ „	31
„ 30–35 „ „ „ „	36
„ 35–40 „ „ „ „	18
„ 40–45 „ „ „ „	17

(2) The infant mortality rate in families who lived in homes with two or more persons per room was 2½ times that in families from homes with less than 1 person per room.

The M.O.H. of Manchester in 1931 applied to the Corporation for the demolition and clearance of the Hulme slum area. In substantiating his case, and in proof of the fact that the area, on account of the bad state of the dwelling quarters, was injurious to health and should be demolished, he had collected the following statistics.

	City		Slum
General death rate	13·9	....	21·8
Infant mortality rate	91·0	....	135 0

and similarly there were higher mortality rates in this slum area from diphtheria, diarrhoea, tuberculosis, diseases of the heart and blood vessels, bronchitis, and pneumonia.

From the very many surveys undertaken it has been established that cerebrospinal fever (meningitis) is closely associated with overcrowding, and in epidemics the incidence rate increases in direct proportion to the degree of overcrowding and amount of space between beds.

Overcrowding and Infection

It must be borne in mind that overcrowding in slum areas does not only mean too many persons occupying a dwelling, though this is of major importance. It also includes overcrowding of buildings in the area concerned, lack of open spaces, the so-called "lungs" of the city, lack of playing-fields, and too narrow streets. Apart from a higher accident rate these all create favourable circumstances for the spread of disease, particularly because such areas are always inhabited by the poorer section of the community, whose vitality is already lowered through the lack of sufficient protective foods, cold, sheer hunger, and all the misery associated with poverty. It is also true that poorer people have more children, which adds to the overcrowding. Under these conditions the human body, lowered in resistance, becomes fertile soil for the reception and cultivation of disease-germs, whose power of infectivity is further increased by the herding together in close proximity.

The most common communicable diseases spread by close personal contact are sore throat, bronchitis, pneumonia, influenza, scarlet fever, mumps, chicken-pox, whooping-cough, diphtheria, cerebrospinal meningitis, and tuberculosis. Many of these illnesses are preventable. In most cases, particularly for measles, whooping-cough, diphtheria, scarlet fever, and the other more common communicable diseases, the earlier in life they are contracted the more serious is the prognosis. The first year of life is the most dangerous age for children to become infected, and the danger lessens as the child grows older. Particular care should therefore be taken to prevent any of these illnesses occurring in the early years of life. The chances of such prevention being effective, however, are very much lessened in overcrowded slum areas. The result is a higher incidence among the lower age group with a correspondingly higher death rate.

The City of Glasgow published the following illustrative figures showing the difference in health conditions in homes according to the number of rooms per house. The figure 100 is taken as a comparative number applied to the house of one room (taken from the *Practitioner*, Sept., 1943).

House of	General Death Rate	Pneumonia and T.B. Death Rate	Infant Death Rate	Death Rate Children 1–5 Years
One room	100	100	100	100
Two rooms	64	72	78	74
Three rooms	44	32	61	44
Four rooms	41	38	49	25

The writer who submitted these figures stated that it did not really matter which year was taken for the statistical inquiry; the relative incidence remained the same.

The Lot of the Slum Dweller

The literature is full of similar statistical proof of ill-health and high mortality rate of the poor. Figures unfortunately cannot register the misery, unhappiness, and wretchedness of squalor, cold, and hunger—the lot of the slum dweller.

Think of the discomfort of leaking roofs, absence of adequate bathing facilities, sharing common dirty w.c.s for whose cleanliness no one seems to be responsible, the lack of proper cooking facilities, and more often than not nothing to cook anyway; and then sitting down in overcrowded hovels to a meal with the smell of cooking, with dirty plates and cooking utensils staring you in the face, and the noise of the neighbours coming from all sides. No wonder the sickness and mortality rates are so high. But we only know of the registered figures of physical illness. What of the mental condition of people who grow up in these surroundings? What do they think of the world they live in, and who can blame them if their souls become filled with hatred and animosity? What sort of citizens do we breed under such conditions and what is their outlook on life? Is it a wonder that "civilized mankind" has been plunged into the greatest effort towards exterminating itself that has ever been known in history? The rich have their animosities and hatreds born and bred in greed and selfishness, and the poor have their minds warped by squalor, hunger, and suffering. Strife and bitterness can surely never end until we "liquidate" these factors; and on their liquidation depend the future peace and well-being of the whole world. These, then, are the inescapable and undeniable physical and mental havocs wreaked upon the slum dweller written in the figures which register life and death, and in the incalculable suffering of poverty and misery which can only be measured in terms of drudgery, depression, and mental anguish.

---

* Paper read at S. African Health Officials' Conference, Johannesburg, Nov. 28, 1944.

No wonder, then, that people in South Africa are anxious to rehouse the poor and to remove the slums. It would, however, be dangerous to seek a solution of this problem by merely providing new houses. It is true that rehousing is a very great factor, but by itself it does not offer a solution. Along with it must come social and economic reconstruction. We must ask what are the most pressing needs of the slum dweller. We do know that people who are badly housed have high mortality and sickness rates. We also know that people who are badly housed are the poorest section of the community. Bad housing is not the only evil which goes with poverty. Inadequate clothing, cold, and sheer hunger apart from malnutrition, are most important factors, and it is useless leaving this problem to those who can think only in terms of dilapidated buildings and overcrowding, and to whom rehousing only means providing new buildings and who think only in terms of bricks and mortar.

The Stockton-on-Tees Object-lesson

McGonigle and Kirby in their book *Poverty and Public Health* (1936) give in detail an example of the folly of looking to rehousing for improving the health of the slum dweller. They describe how the medical officer of health of Stockton-on-Tees once decided to apply to the Council for the demolition of an unhealthy area and for the rehousing of the inhabitants. As the area was too big to be dealt with under one scheme it was decided to divide it into two portions and first to rehouse one group, and to leave the rest until later.

The slums in the one area were demolished and the inhabitants removed to a modern self-contained housing estate. There was no appreciable difference in the original social, economic, and housing conditions between the people removed and those who remained behind. In this way 152 families and 710 individuals were moved to a newly constructed housing estate, and 289 families and 1,298 individuals remained behind. This offered very suitable conditions for the study of the results of rehousing, particularly as a thorough record of the total statistics of the area had been kept prior to the demolition of the one portion.

For the five years before removal of the one area the death rate for the whole of Stockton-on-Tees was 12.32, for the area not demolished 26.10, and for the demolished area 22.91. These figures show a higher death rate for the slum areas when compared with the whole city and a higher death rate in the area undemolished when compared with the area which was cleared.

Records were then kept for the next five years. The death rate for the whole of Stockton-on-Tees came down from 12.32 to 12.07, that of the people left in the slum area from 26.10 to 22.78, but the people who were removed to the new housing estate showed an increase in the death rate of from 22.91 to 33.55! It might be thought that the populations were not similar, and that there was, say, a preponderance of old people in one or other area. This can be dispelled, because all these rates were "standardized" to allow for any discrepancies in the make-up of the populations. There was also no untoward occurrence such as an epidemic in any particular area.

When these facts became evident it was necessary to determine the reason for such adverse conditions among the very people who had considered themselves fortunate in being rehoused in such attractive, new, well-appointed homes and under such pleasant conditions.

The cause was not difficult to find. The rentals in the old slum areas were about 4s. 8d. per family per week and the rentals for the new houses were 9s. per week. All these families were among the very low income group, and an increase from 4s. 8d. to 9s. is almost double. A survey was made of the income of the families in both areas, and it was found to range between 47s. 1d. and 30s. 5d. among the rehoused and 44s. 7d. and 30s. 9d. among those who remained behind. This shows that the income levels were about the same. But the occupants of the new homes were paying about 25% of their already meagre income in rent, and those in the old homes only 17%. To poor people this is a very big item in the family budget. In addition there were also new social obligations involving small extra expenditures among the rehoused. With an average weekly income ranging between 47s. 1d. and 30s. 5d. per family it goes without saying that these families never indulged in luxuries which could now be cut down to meet the increase in rentals. Their clothes already were of the bare minimum, and the only item on which they could save was food. They were actually dying of malnutrition—killed by the kindness of a well-meaning but short-sighted rehousing policy. This story serves as an object-lesson to all who deal with rehousing and slum elimination. It is a dangerous business unless all economic factors are taken into consideration.

A very interesting figure brought to light by this survey was the infant mortality rate. The authors hardly comment on it, but it really is of great significance and adduces further evidence of the importance of nutrition when coupled with rehousing.

Infant mortality was the only death rate which was reduced in the new estate. It came down from 172 to 117.8. As previously mentioned, infant mortality rate refers to deaths in infants under 1 year of age—an age period when for the most part nearly all children live on mother's milk, a perfect food for babies and the cost of which does not figure on the family budget, with the result that the general lack of food did not affect them. This substantiates two important findings. First, that malnutrition must have played a great part in increasing sickness and mortality rates among those over 1 year of age. There was actually an increase of 9.2% in the death rate of children between 1 and 10 years of age! And, secondly, that in the breast-fed and better-nourished infants under 1 year the healthy new surroundings and new homes played a great part in the reduction of the infant mortality rates.

Economic and Social Factors

Rehousing and slum elimination are essential. But what are the most urgent needs of the poor if we think in terms of mental and physical well-being? I would say without hesitation that it is at least as important to provide a sufficient supply of all the essential foodstuffs and adequate warm clothing. This provision must not be a "from-day-to-day hazard; it must be part of a social security system which will provide these basic amenities of life for all those who are prepared to do an honest day's work. It must also provide for the children, for the sick, and for the aged. Such a system will remove the anxiety and mental anguish associated with insecurity. With this there should be adequate free medical attention and hospital provision.

It is essential that *work* should be provided for all. There can be nothing more demoralizing than being on the dole. There should be a remodelling of our economic system. The primary object of production should not be for gain or exportation but to meet demands and provide the people with what they need. This would secure lasting employment for everybody, with incomes, and with goods to buy with these incomes.

Any attempt to increase wages without price control or, what amounts to the same thing, without control over the supply and demand factors, is merely the beginning of another vicious circle. We must have adequate wages, but we must also see that labour is directed towards the production of the things we need most. It is only in this way that the wages of labour will have a purchasing power which will at least permit of sufficient food and clothing as well as satisfactory housing. But we must not let housing by itself be considered as priority No. 1; other factors are at least as important.

I do not desire in any way to detract from the importance of and necessity for decent dwelling-houses. There is no doubt whatsoever that slums and bad housing are factors of the utmost importance in causing ill-health and disease. But they are not the primary factors. It is good that slum dwellers should be rehoused, but it must be ensured that the rentals of the new houses are not more than those of the old, and that persons rehoused will at least have sufficient money left after paying rent to provide for other essentials.

A Problem to be Tackled as a Whole

My main point is that we must not take for granted that rehousing is a cure for sickness among the poor. Unless the whole problem is tackled by a combined team of engineers, town planners, architects, social welfare workers, doctors, health inspectors, health visitors, qualified housing manageresses, economists, and medical officers of health the problem does not receive the attention which is necessary to attain the desired result.

Are we doing this in South Africa, or does rehousing to us still only mean putting people into new structures? Perhaps we *are "considering"* all these factors, but it cannot be said that there is a co-ordinated effort for its practical application. How can we have full co-operation when housing is dealt with by municipalities, and economics largely by the central Government? The production of foodstuffs is regarded as practically a purely agricultural problem, whereas we know that it can receive full consideration only from the point of view of what should and could be grown and distributed most economically in terms of "food value" for the people, when studied by a team of agriculturists, economists, veterinarians, and doctors.

It is quite evident that this question of health and housing is a problem which goes much further than most people realize. It requires to be viewed from a new angle and in its broadest aspects. It can be adequately dealt with only by a combined effort, based on knowledge and understanding.

THE R.A.F. MEDICAL SERVICE, 1939-45

On the formation of the Royal Air Force in April, 1918, medical officers who had served with the Royal Naval Air Service and the Royal Flying Corps were transferred or attached to the new Air Force and were granted R.A.F. ranks in November of the following year.

Although there were 415 officers in the medical branch when it was formed this number had dropped to 132 by the end of 1919, and the figure fluctuated with the rise and fall in strength of the Royal Air Force between the two wars. The formation of the R.A.F.V.R. in 1937 enabled a reserve of medical officers to be built up totalling 175 medical officers at the outbreak of war. The total strength on the same date was 554, including 91 officers from various reserves and the retired list. Recruitment for the R.A.F. as a whole had not reached any large proportions and the ratio of medical officers per 1,000 personnel was 4.5. This fell to 2.18 per 1,000 personnel by September, 1941, remaining practically at that level throughout the war.

The medical officers were faced with a formidable variety of duties, and lack of experience in total warfare placed an additional and unknown burden on them. The existing medical organization had to be expanded smoothly and rapidly, and facilities provided for the medical examination of entrants at medical boards all over the country. Health had to be maintained and sickness and disease prevented. Wounded had to be healed and rehabilitated and returned to their Service duties as quickly as possible, and the statistical organization had to be greatly expanded.

Organization

The R.A.F. Medical Services are in the Department of the Air Member for Personnel and are headed by the Director-General of Medical Services. The chain of medical liaison and control is maintained by the Director-General and his staff in the Medical Directorate through principal medical officers and senior medical officers down to the medical officers of units. The unit medical officer is a vital link in the chain. Being in close touch at his station or squadron with the practical problems of unit or station life he must maintain a constant watch over the physical and psychological health of all aircrews. All medical officers are given a series of lectures and demonstrations by experts on the psychological health of personnel. Psychologists visit stations and discuss problems with the unit medical officers and also explain to the squadron commanders the common-sense approach to the psychology of aircrews.

Sick Quarters and Hospitals

In 1940 there were seven R.A.F. hospitals at home and two abroad; by the end of 1944 there were 26 R.A.F. hospitals at home and 13 over-seas, as well as a number of mobile field hospitals abroad. The latter were well equipped and could provide all essential services for front-line medicine and surgery. In oversea theatres of war the value of R.A.F. hospitals of all kinds was not only in the first-class facilities for treatment which they afforded; equally important was the expert technical knowledge necessary for determining a man's fitness for his trade. 92% of aircrews and technicians treated in forward areas at mobile field hospitals were returned to their units in a very short space of time, after assessment by R.A.F. medical officers.

The R.A.F. has hospitals and sick quarters in the United Kingdom to look after all R.A.F. personnel—ground, technical, and aircrew. R.A.F. hospitals abroad are primarily for aircrews and technicians. The Army method of dealing with casualties is to evacuate them down the line as quickly as possible to keep the front line clear for action. In the R.A.F. it takes so long to train aircrews and technicians that it is necessary to save every man possible. If a member of an aircrew or technician is likely to be fit for duty in from 6 to 8 weeks he is treated in an R.A.F. mobile hospital in a forward area. Of selected cases approximately 92% have been got back to duty in the field. The R.A.F. treats its own cases, whether long- or short-term. It has instituted rehabilitation both in hospitals and at separate centres. Of rehabilitation cases, approximately 80% of all fractures have gone back to full duty, 60% of burns, and 46% of nervous breakdowns. It treats its own cases of tuberculosis and retains them in Service hospitals until local authorities can take them.

Dietetic Researches

A team of experts watched over the diet at hospitals both at home and abroad and advised upon any deficiencies in calorific value or vitamin content. This service also covered the dietetic needs of the whole of the R.A.F. at home and abroad.

All fronts were covered at different times, some fronts more frequently than others, to see that the nutritional state of the R.A.F. was satisfactory. In Europe there was an opportunity at the same time to ascertain the ill effects of under-nourishment on certain of the civil population, including children. By feeding these individuals with the substances that it was considered they were most lacking, not only was their condition improved or cured but valuable information was obtained for our own use. This information become useful sooner than we expected, as the sudden ending of the war cast on our hands a large number of prisoners of war who had been exposed to forced marches with little or no food and had suffered severely. The information gained previously in the treatment of civilians made it possible to give immediate and most satisfactory treatment to our ex-prisoners of war.

The results of the dietetic researches carried out in the R.A.F. are immediately passed to the sister Services, Ministry of Health, Ministry of Food, and the Medical Research Council for their benefit, as well as to the Dominions and the United States of America.

Sickness Figures

The highest incidence of sickness at home was during the years 1939 and 1940, and coincided with a severe winter under wartime conditions and the influx of a great number of men and women into the R.A.F. and W.A.A.F. from civilian life. In 1942 and 1943 sickness at home fell sharply to low level and the improvement in health has been maintained.

The worst years for incidence of sickness over-seas were 1940 and 1941. R.A.F. personnel were then being posted in substantial numbers to unhealthy climates, and the provision of preventive measures in the absence of the necessary materials was slow, laborious, and costly. The introduction of full preventive measures, including inoculation against a variety of diseases and the issue of drugs to personnel, and the improvement of hygiene and living conditions, produced a sharp fall in the rate of sickness in the R.A.F. abroad in 1943, and has persisted since.

Prevention of Disease

Hygiene during the war presented a variety of problems which had to be faced and overcome. Among them were the selection of personnel and the detection of disease, the maintenance of proper living conditions at home and abroad, the prevention of the spread of disease from one country to another by aircraft, control of hours and conditions of work, prevention of air-sickness, and the safeguarding of dental health.

The introduction of mass miniature radiography in the Royal Air Force in 1941 disclosed much of value and interest about chest conditions as a whole, apart from tuberculosis of the lung. By the end of the year 1944 a total of 480,492 examinations had taken place. The Royal Navy, which introduced mass radiography before the war, was the first Service to have it. The R.A.F. was the first Service to have mobile miniature mass radiography.

Evacuation of Casualties by Air

Great progress was made in 1942, 1943, and 1944 in the development of an organization for the evacuation of casualties by air. The figures for 1940 were about 300, and for 1941 some

2,000. Evacuation on a large scale began during the campaigns in the Western Desert and Libya; after Alamein the numbers reached 2,000 a month, and in November and December they were approximately 200 a day. 1943 saw the development of the casualty air evacuation units and sections, and the responsibility for the evacuation of casualties by air to Transport Command, 28,000 casualties being evacuated in that year, mostly from the Mediterranean Theatre.

In 1944, following the invasion of Europe, very much greater numbers were evacuated from Western Europe to Great Britain. During the second week of August, 1944, the daily total evacuated by air surpassed the daily number evacuated by sea, and after September the numbers evacuated by air were constantly higher than those brought by sea, except for two short periods in October and November. August, 1944, saw the introduction of a shuttle service from forward to base airfields. This service greatly shortened the time which sick and wounded had to spend in travel, and between August and the end of the campaign in Europe some 42,000 patients were evacuated by this service. Between June and the end of the war in Europe 82,000 cases were evacuated by air to the United Kingdom, and the total of cases throughout the world evacuated by the R.A.F. amounted to 300,000 for the year 1944. About 92% of these were Army personnel, and about 5% of cases evacuated from the European Theatre were American personnel. The R.A.F. brought out by air 60% of the British casualties in Western Europe, excluding prisoners of war, whereas in the Far East almost 100% in forward areas were brought back by air and the chances of recovery greatly increased. The number of ex-prisoners of war brought back to this country by air was 144,188.

HOSPITAL NURSING STAFFS

FACTORS IN ASSESSING REQUIREMENTS

The new Minister of Health has confessed that his Ministry is "haunted" by the dangerous depletion of hospital nursing staffs and by the fact that wards are closing down all over the country owing to lack of nurses. In this connexion a recent report by a committee (presided over by Dr. Morley Fletcher) of King Edward's Hospital Fund for London is very timely. The committee deplores the fact that too often questions of staffing are decided by financial considerations. "The salaries bill is looked upon as one of the heaviest items of expenditure, whereas in terms of value for money it is perhaps the most economical."

Factors to be taken into account in assessing staff requirements are: (1) space, such as the general lay-out of the hospital, length of corridors, and size of wards; (2) size of domestic staff; and (3) reserve or pool of nurses needed to replace those on holiday or sick leave. Further considerations apply to hospitals which are training schools, such as recognition of the student status of the nurse in training, and the block system of training whereby student nurses are withdrawn from ward duties for a term of theoretical work each year.

Estimated Ratios

To decide the optimum ratio of nurses to patients is not easy. A rigid standard of so many nurses for each 100 beds should not be imposed regardless either of the size of the wards or of the type of case to be nursed. Nevertheless, the committee does suggest the ratio of 70 ward nurses to 100 beds, the ward staff to be made up of 5 sisters, 5 trained nurses, 10 fourth-year student nurses, and 50 first- to third-year student nurses. This does not allow for the block system of training, and if the block system is introduced there should be an increase of one-fifth in the recommended number of first- to third-year student nurses, making their number 60 and bringing up the number of total nursing staff to 80.

As for the relations between numbers of ward staff and numbers of nurses engaged in other duties in the hospital, it has been ascertained that the total of nurses engaged in such other duties varies between 19 and 38% of the number engaged in the wards, the proportion being markedly higher in the smaller hospitals. If, therefore, the ratio for the wards is 70 nurses to 100 beds, not allowing for the block system, an addition of 38% for the administrative and departmental staff would give 96 as the total of the nursing staff for 100 beds. This leads to the conclusion that some general hospitals with out-patient and other departments may in future have to plan for a total nursing staff approximating to one nurse to each in-patient bed. In special hospitals the requirements might be even greater.

The King's Fund Committee recommends that those hospitals which can staff on adequate lines should not underestimate their requirements of nursing staff, but should set a standard of conditions of nursing care which would enhance the reputation of nursing as a career and help recruitment to the profession.

The report has several recommendations to make on hours of duty and on accommodation for nurses. With a more generous allowance of trained staff there is room for some modification of the shift system, and experiments in this direction are to be encouraged whenever sufficient staff is available.

QUEEN'S INSTITUTE OF DISTRICT NURSING

MIDWIFERY CASES IN 1944

The following report on midwifery cases attended by the Queen's Nurses and village and other nurse midwives shows the results for the year 1944.

The number of maternal deaths was 85, and the maternal mortality of 1 per 1,000 total births for the year was the lowest ever on record. This is an achievement of which the midwives may well be proud, particularly as it was in a year full of anxiety and strain for the mothers and themselves. It is puzzling to find that in spite of careful antenatal supervision the number of cases of eclampsia is still too high, and in many cases no symptoms could be detected prior to the eclamptic condition. It suggests that some further research on this complication would be valuable.

Among the maternal deaths in this report 58 occurred in hospital, of which 18 are classified under "accidents of labour," the term including ante- and post-partum haemorrhage, obstetric shock, heart failure, etc. Every patient booked with the midwife is followed up to the end of the case, whether the midwife completes the attendance herself as midwife, or it is transferred to a doctor or to a hospital. The maternal mortality, therefore, includes all complicated cases; many of these would have been doctors' cases had the patients been able to afford to pay the doctors' as well as the midwives' fee.

The number of cases attended (no doctor engaged for the confinement) was 85,153. The total number of midwives was 4,253, of whom 1,633 were Queen's Nurses and 2,620 were village and other nurse midwives. Of the patients attended, 20,664 were primiparae.

Analysis of Maternal Death Rates

Year	Puerperal Sepsis	Other Puerperal Causes	Total Puerperal Mortality	Non-Puerperal Causes	Total Maternal Mortality
			Per 1,000 *live births*		
1942	0·21	0·89	1·10	0·09	1·19
1943	0·33	1·01	1·34	0·04	1·38
1944	0·12	0·82	0·94	0·07	1·01
			Per 1,000 *total births*		
1942	0·20	0·87	1·08	0·09	1·17
1943	0·32	0·99	1·31	0·04	1·35
1944	0·12	0·81	0·93	0·07	1·00

The number of times medical aid was sent for was: For mother, 28,616 (33.6%) (during pregnancy 5,736, during labour 19,784, and during puerperium 3,096). For infant, 5,129 (6.0%). The number of forceps cases was 3,648 (4.3%).

Causes of the 85 Maternal Deaths

		Per Total Maternal Deaths	Per 1,000 Births
Sepsis	10 cases	11·8%	0·12
Accidents of labour ..	29 „	34·1%	0·34
Eclampsia	11 „	12·9%	0·13
Embolism	7 „	8·2%	0·08
Complications ..	22 „	25·9%	0·26
Non-puerperal ..	6 „	7·0%	0·07

There were post-mortem examinations in 18.8% of the maternal deaths, compared with 25.4% and 27.1% in the two previous years.

The figures for maternity nursing in 1944 were: Number of cases attended (doctor engaged, midwife acting as maternity nurse), 44,545. Number of maternal deaths, 57 (1.28 per thousand). Three deaths were due to miscarriage; these being doctors' cases the details were not verified.

VACCINE AGAINST SCRUB TYPHUS

A CO-ORDINATED EFFORT

The outbreak of war in the Far East brought many problems to the Allied High Command, particularly in relation to infective diseases. Among these was scrub typhus, a disease infecting rodents in Asia and Australasia, transmitted by mite larvae ("harvesters") and contracted by human beings living in jungle and grassland infested by the mite. As Allied troops pushed into Burma and New Guinea, and other regions where jungle warfare conditions prevailed, there was a marked rise in the incidence of the disease. It has a considerable mortality rate, and in most cases the illness is protracted and incapacitating. It is most prevalent during or immediately after the monsoon seasons.

Research work has been carried out in many parts of the world on scrub typhus vaccine, and as a result of the co-ordination of the efforts of scientific workers in the United States and the United Kingdom, medical research workers at the National Institute for Medical Research, Hampstead, were able in 1944 to work on lines which finally resulted in a suitable vaccine being prepared for clinical trials. By the end of 1944 the Army High Command in the Far East sent a request for 1½ million doses of this vaccine. It was asked that as large a quantity as possible should be made available for immunizing troops in combat areas before the onset of the monsoon and the accompanying increased risk of infection with mite-borne typhus fever.

Race against Time

To translate a laboratory technique into a manufacturing process requires time, but in the case of scrub typhus vaccine speed was the essence of the scheme. After discussion with the War Office, the Ministry of Supply, and the Medical Research Council, the Wellcome Foundation Ltd. was asked to undertake the work. The project was given a secret code name, and it was decided to erect the laboratories and animal breeding houses at the Wellcome Veterinary Research Station at Frant, Sussex.

In view of the extreme urgency of the required buildings and the difficulty of getting adequate civilian labour, as a result of bomb damage repair work going on in Southern England at the same time, the building operations were carried out by the Army. A company of Royal Engineers, with Pioneers and specialist contractors, began work on Jan. 14, 1945. On May 4 the laboratories were ready, including specialist equipment, much of which was of an entirely new design. The highest priority for materials and apparatus was afforded, and equipment not available in this country was obtained by air from the United States. The design of the laboratories, together with the responsibility for implementing the scheme and the production of the vaccine, was placed with a director loaned by the Medical Research Council to the Wellcome Foundation.

Supply of Essential Animals

The method of manufacture required the use of large numbers of cotton-rats. These rats are indigenous in the southern States of North America (Louisiana, etc.), and in order to establish breeding colonies in this country and get sufficent animals for producton of the first batches of vaccine, cotton-rats had to be obtained from the U.S.A.

Weekly shipments of animals were sent by air across the Atlantic in specially heated aircraft, these consignments having the highest priority. The rats on arrival in this country were brought down immediately to Sussex, sometimes by air but in most cases by Service transport.

Protection of Trained Personnel

To provide personnel for the animal houses and laboratory work, A.T.S. and R.A.M.C. were specially selected and trained in the work they had to carry out. Scientific officers were recruited from the R.A.M.C. and scientific bodies in this country. In view of the high risk to which all personnel would be exposed in the preparation of scrub typhus vaccine, great precautions were taken to reduce this risk to a minimum. Special equipment was designed and built, incorporating new principles of air sterilization. Further, all engaged on the work were immunized, and strict control was exercised over the disposal of infected material.

As a result of the co-ordination of all concerned it was found possible to prepare 100,000 doses of the vaccine for shipment to the Far East at the time required by the Army authorities. Preparation of additional quantities is proceeding.

JOINT TUBERCULOSIS COUNCIL

The Joint Tuberculosis Council held a special meeting on July 21 at the London School of Hygiene and Tropical Medicine, to consider some important reports prepared by committees, and the following statement has since been drawn up for the medical press.

Notification of Tuberculosis

The Committee on Notification of Tuberculosis, which has for some time been considering whether the present method of notification really achieved the best results, proposed some important changes in the system. The most notable is a suggestion that notification in the future be a two-stage procedure. The first stage would be that of *intimation*. A practitioner, suspecting that a patient might be tuberculous, would be able to send a non-committal intimation to the local authority instead of, as now, being compelled to make up his mind and decide upon a definite diagnosis of tuberculosis, which automatically puts the patient on the register of tuberculous persons. Under the new procedure the final diagnosis of the patient, and therefore the responsibility of placing him on the register, would rest with the tuberculosis officer. At the same time, there would be nothing to prevent the general practitioner who was certain of his ground from notifying the patient exactly as is done now. The value of the suggested new system would be that provision would be made for the doubtful case, whose illness could be thoroughly investigated by a tuberculosis consultant without any possible "registration stigma" in the event of his turning out not to have the disease. The Council decided to forward the committee's report to the Ministry of Health and to suggest that a meeting be arranged to discuss the best methods of achieving its objects.

Memorandum 266/T

The Council will shortly publish the interim report of the Committee on Ministry of Health Memorandum 266/T. This report raises three different kinds of issues arising out of that memorandum. First, there are administrative amendments, which could be authorized quite simply by an amending memorandum. Secondly, there are many points on which interpretative guidance is needed by bodies and officers administering the scheme; these could be dealt with by Ministry circulars, or guidance could be given by an authoritative body such as the Joint Tuberculosis Council itself. Thirdly, there are the matters in which information rather than specific action is necessary. Some method is urgently needed whereby administering authorities can exchange information and pool their experience. The committee believe that the basic monetary allowance under 266/T should be substantially increased and that dependants' allowances should be increased also.

Sanatorium Staff and Mantoux Test

The third main subject dealt with at the Council meeting was the conversion of hospital and sanatorium staff from Mantoux-negative to Mantoux-positive. It was decided to prepare a memorandum of advice on this subject, to be published shortly. The main points of the memorandum will include a month's "work and bed" for staff presenting no symptoms, no radiological evidence, and no significant increase in the sedimentation rate. For the symptomless with an increased sedimentation rate, a month's "half-duty and rest" is suggested, and if at the end of that time the sedimentation rate was normal, full duty would be resumed. For those without symptoms but with enlarged hilar glands and an increased sedimentation rate, a month in bed is the recommendation, to be followed by a month's "half-duty and rest" if this succeeds. Those who are actually ill, of course, are treated for as long as is necessary. It is most important, the J.T.C. believes, that Mantoux-negative staff should be told that they are negative, and that they are almost certain to become positive. They should also be told that just as most town dwellers go through a primary tuberculosis infection at some time in their lives and know nothing about it, the same uneventful course is probably the lot of the sanatorium nurse or maid changing from negative to positive.

Dr. Robert Young Keers has been appointed medical director of the Red Cross Sanatoria of Scotland, which are being established at Tor-na-Dee and Glen o' Dee by the Scottish Branch of the British Red Cross Society for the treatment of ex-Service men and women who have contracted pulmonary tuberculosis as a result of their war service. Dr. Keers, who is a graduate of the University of Edinburgh, has had a wide experience of tuberculosis work both in Britain and on the Continent. Since 1939 he has been medical superintendent of Tor-na-Dee Sanatorium.

Correspondence

Penicillin and Synthetic-Rubber

SIR,—Neither in papers describing different methods of giving penicillin by continuous intravenous or intramuscular drip, nor in hospitals one visits on returning home from the Services, does one see or hear any reference to the deleterious effect of synthetic rubber on a solution of the drug. This effect was known in B.L.A., and it was re-tested and confirmed by Major Craik, specialist pathologist, in Italy. Most of the rubber tubing now issued is of the synthetic variety, white or red; and it is a proven fact that contact with such tubing for an hour or two during the slow passage that a drip apparatus demands almost completely destroys the potency of the penicillin. Natural red rubber, on the other hand, has almost no ill effect. For this reason we in Italy used to collect all the natural rubber tubing we could lay hands on for continuous penicillin therapy. Some of the varying or disappointing results obtained in different centres, or even in the same centre at different times or in different hands, may well be due to the fact that natural rubber was used on some occasions and the synthetic variety on others.—I am, etc.,

F. A. R. STAMMERS,
Birmingham. Late Consulting Surgeon, Forward Areas, Italy.

Administration of Penicillin

SIR,—In assessing the relative merits of the administration of penicillin by continuous infusion and repeated injections (Sept. 1, p. 283) I think that much depends upon the nature of the cases being treated. My conclusions from a similar number of cases are the reverse of those found by Dr. E. C. Turton. Over 90% of the patients preferred repeated intramuscular injections. The main reason for this was that a continuous drip kept them confined to bed, and separate injections gave them a great deal more freedom of movement, and a chance to be up and about between doses. I must add, of course, that all the patients concerned were either primary or secondary syphilitics and mainly ambulant cases.—I am, etc.,

Grove Hospital, London, S.W.17. SYDNEY JONES.

Pituitary Snuff and Duodenal Ulcer

SIR,—For some years the use of pituitary snuff in the treatment of duodenal ulcer enjoyed a vogue, chiefly in Germany, and has more recently been encountered here. My notice was first drawn to it by seeing two cases of profuse malaena and one of duodenal perforation in patients undergoing the "cure."

Dr. John Stevenson (Sept. 1, p. 298) is optimistic, and writes that many hundreds of working hours have been saved by such ambulatory treatment. Its basis is as irrational as was that of histidine therapy, now nearly extinct. That, however, would be of small account if it really did what was claimed for it. But does it? We must discount Dr. Stevenson's own case, because all sufferers from duodenal ulcer, and doctors more than most, are prone to benefit from suggestion. We are then left with 75 men treated from Oct. 27, 1944, to April 2, 1945—i.e., five months and a few days. During this period 60 had no pain. Presumably 15 did suffer relapse. A five-months remission of symptoms in 71% of a series, made up of men who had had this trouble for from 1 to 20 years, is merely an indication of the natural history of the duodenal ulcer. If Dr. Stevenson had not been forced by circumstances to terminate his observations so early, and had he been able to produce an 18-months observation with the same results, then the discovery of a useful therapeutic agent would have been suggested. Even so, the phenobarbitone should have been omitted, and the results given in relation to the length of history of ulceration. I and many others obtained equally good "results" from the treatment of ambulatory out-patients with injections of histidine or, alternatively, distilled water! May it not be that the full diet and the confidence inspired by a new treatment were responsible for the apparent success?—I am, etc.,

London, W.1 A. H. DOUTHWAITE.

Routine Rh Testing

SIR,—The valuable article by Plaut, Barrow, and Abbott in the *Journal* of Sept. 1 indicates that routine Rh testing of women attending ante-natal clinics and maternity departments is becoming increasingly common, and it is hoped that ultimately it will become universal. The information that an expectant mother is Rh-negative is of value to the obstetrician in giving warning (*a*) of the risk of haemolytic disease in the foetus, and (*b*) if the mother should require a transfusion.

Plaut *et al.* record their results in two series, the first tested with standard anti-Rh_0 serum (anti-D or Δ), the second with anti-Rh_0, anti-Rh′ (anti-C or Γ), and anti-Rh″ (anti-E or H). The authors have followed the writer's practice of including in the Rh-negative groups those persons recognized in the second series as belonging to subtypes Rh′ and Rh″. In my opinion human red cells should be classified into 4 Rh-positive types comprising Fisher's Rh_z (CDE), Rh_1 (CDe), Rh_2 (cDE), and Rh_0 (cDe), and four Rh-negative types comprising Rh′ (Cde), Rh″ (cdE), Rh_y (CdE), and rh (cde). The possession of the dominant antigen D is the fundamental thing which should determine whether an individual requiring transfusion is called Rh-positive or Rh-negative; this is the component, identified by immune anti-Rhesus sera in Landsteiner and Wiener's original work, which most commonly gives rise to iso-immunization in the human subject.

From the therapeutic standpoint the individual who lacks antigen D should receive by transfusion only Rh-negative blood of genotype rhrh. In assessing the constitution of the prospective donor, however, all persons other than those of genotype rhrh should be excluded. About one-half of the Rh-negative (rhrh) women sensitized by an Rh_1 foetus react by producing agglutinins of both anti-Rh_0 and anti-Rh′ types (i.e. anti-Rh_1 sera); while those sensitized by an Rh_2 foetus may produce anti-Rh_0 and anti-Rh″ agglutinins (i.e. anti-Rh_2 sera). Individuals whose serum contains anti-Rh_1 or anti-Rh_2 agglutinins are likely to experience a sharp haemolytic transfusion reaction if given blood of subtype Rh′ and Rh″ respectively. Thus there is a small percentage of persons of subgroups Rh′ and Rh″ (totally about 2%) who must be counted as Rh-negative when recipients of blood but should not be used as Rh-negative donors. The provision of Rh-negative blood for transfusion is generally a matter for the blood bank and Regional Transfusion Officer, and the use of the three anti-Rh sera by this responsible authority is necessary to determine the completely Rh-negative character of the blood for transfusion. In the testing of the recipient only one potent anti-Rh serum need be used—namely, that of anti-Rh_0 type (anti-D or Δ)—and antisera containing anti-C or anti-E should be avoided, so that confusion of the subgroups R′ and R″ with the true Rh-positive types containing antigen D will not occur—I am, etc.,

The University, Glasgow. D. F. CAPPELL.

Diminution of Vision in Returned Prisoners of War

SIR,—It is now becoming more and more evident that the syndrome of sore tongue with cracked lips (cheilosis), dry furfuraceous skin, dry scaly scrotum, accompanied in many cases by various nervous manifestations, more particularly a retrobulbar neuritis (which if left untreated passes on to a partial optic atrophy of varying severity), has been an affection of many of our prisoners of war in Japanese hands—especially in some camps. Will you permit me to make some comments on this subject? First, the whole syndrome has been very fully reviewed by H. S. Stannus in his Lumleian lecture of 1944, of which abridged accounts appeared in the *British Medical Journal* of July 22 and 29, 1944, accompanied also by a very full bibliography. Therefore no useful purpose would be gained by making reference here to the more detailed description or the aetiology of the condition. But I would like to say a little about treatment—from personal experience in West Africa in the study of this condition there over a number of years (1930–8); and more particularly with regard to impaired vision (which, after all, can be the most serious of all residual effects).

As a general rule I found it worth while to treat all cases having a history up to 12 months. Over that period improvement was problematical unless, of course, the patient was still suffering from subacute effects of his malnutrition, as was so commonly the case among Africans who by virtue of their visual defect were often unable to earn a living. These cases, in which diminution of vision had become manifest in less than a year, generally showed good prognosis, and those with a history of six months or less an excellent one. It was usual, however, in cured cases to find some mild intolerance on the continued reading of small print; also there was often a *persistent* photophobia (more marked, of course, in a tropical country).

I gave 1 oz. a day of marmite, and continued this high dosage over a period of at least six months. In favourable cases visual response began to become evident within some three to six weeks, usually about "1 Snellen line a fortnight." Others were much slower, while a considerable number had reached an irreversible stage and did not improve. Occasionally, however, one obtained unexpected and unhoped-for results where all the signs suggestive of irreversible changes had intervened. For that reason alone persistence in treatment was always justified. With regard to irreversible changes, in Nigeria (as I have reported elsewhere) I was able in a number of cases to trace patients' histories back over many years: some as far back as 1907. From these inquiries it was evident that this syndrome was very prevalent indeed among the old Government *boarding* schools of those days. It is worth recording, perhaps, that none of these patients had become blind, their condition remaining practically stationary over the years, in contradistinction to progressive changes occurring in primary optic atrophy, with which this condition could be quite easily (in some cases) confused. It was also personal experience, as reported upon again elsewhere, that absolute blindness did not occur, though in many cases central visual acuity was often reduced to hand movements, and, in a number, permanently so.

With regard to mouth and skin lesions, it is necessary to stress how rapidly these (but not vision) clear up, with good food and with active therapy, in a space of 10 to 14 days. This point is of importance, because the vast majority of my own patients did have these signs in the first manifestation of their illness, but later these disappeared, so one must question patients with regard to their history.

In West Africa I did not use riboflavin—it was not available then—but there is little doubt that riboflavin "deficiency," as Stannus has shown, plays a major part in this condition. Probably, however, as he also agrees, other factors of the B^{2} complex are involved. Presumably, therefore, it would be wiser in general treatment to include the whole of the vitamin B complex. It is to be hoped, however, that extensive investigations with riboflavin will soon have been carried out, particularly with reference to visual response, in these other cases now that once more opportunities for further study have presented themselves. No doubt in this respect we shall also gain much valuable knowledge from our American colleagues.

Marmite was exceedingly well taken by Africans, because its salty taste also appealed to them. How far Europeans would accept marmite in these necessarily large doses is difficult to say. I found—in common with general experience—that brewer's yeast was not liked, though it was accepted in the hope of a cure. No doubt "food" yeast will play a valuable part in continued treatment of these European cases. But is it generally available, and, if not, can steps be assured that it would be available to this class of patient after he leaves hospital, as well as marmite?

I understand that, with regard to food itself, present allowances for an extra-nutritious diet are made only for a comparatively short specified period of time to repatriated prisoners of war. It is essential to view a highly nutritious diet for these cases as an integral part of treatment. Can we be assured that this will be available over any necessary prescribed period—say at least six months?

One further observation here might not be out of place. It was fairly certain this syndrome would become manifest under the conditions in which our prisoners of war have lived in Japanese hands. The dietary is, in fact, in many cases—especially those who were housed in jails—very similar to some of the dietaries experienced in West Africa—viz., rice and manioc, with occasionally some sweet potatoes, a little fish, some green food, and red palm oil—the latter fortunately rich in vitamin A precursors; and "what else they could pick up." In the *Journal of Tropical Medicine and Hygiene* of Sept. 1, 1942, I stressed the danger of certain staple carbohydrate foodstuffs when eaten to excess, where the general dietary itself also was poorly balanced. Such foodstuffs named were rice, manioc, sago, sugar-cane. One is convinced then of the need for better-class and more varied *carbohydrates* as an essential consideration, affecting dietary problems of local peoples over-seas. There is a grave danger in emphasizing the good qualities of rice among peoples of the poorer community there. It is not enough merely to demand more protein as the solution of their problems. It is of equal importance for us to realize, as McCarrison has done, the need for variation and availability of staple carbohydrate foodstuffs.—I am, etc.,

D. FITZGERALD MOORE.

Domiciliary Midwifery and the Family Doctor

SIR,—The joint authors of the above article (Sept. 1, p. 294) are representative of the thoughtful and experienced practitioners who view with concern any suggestion that the usual family doctor is not the proper person to conduct confinements. Whether their arguments apply to the majority of the profession to-day is another matter. Almost all the facts presented by the authors are true, but the reasons therefor are capable of other interpretation. They differ, for example, from those of the Royal College of Obstetricians and Gynaecologists and they are not held by maternity hospitals or by the majority of midwives. Who, then, is to judge what is best for the woman? She herself is seldom consulted, because it is presumed that her judgment is obscured by housing, domestic. and financial worries. The patient, however, pays the obstetric piper and her chosen theme is heard in local authority policy. It is not generally recognized that the bulk of midwifery practice is heavily subsidized by rates and taxes. In my own area approximately 50% of all burgh births occur in the municipal maternity hospital, and another 38% come under the domiciliary scheme. In other words, the burgh subsidizes over 80% of all confinements.

The popularity of the hospital is neither recent nor entirely due to bad housing, as the authors would suggest. Some of the beds are private, and many women who have had as many as six children in the hospital come from good houses. Most of the mothers in this burgh are seen at my office or in the burgh maternity hospital, and I can assure the authors that most prefer hospital to their own homes because (*a*) it is cheaper, and (*b*) it relieves them of nursing and domestic difficulties. It scores over the domiciliary scheme also in that they are maintained, and they know in advance their financial liabilities whatever complications may arise. It was only by very preferential treatment that the domiciliary scheme could be got going locally, and the non-enthusiasm was shared initially by patient and practitioner alike. It is very significant that the occasional applicant who considers her assessment too high invariably asserts that she would as soon have the *midwife* alone.

I agree with the authors that the risk of infection is infinitely greater in hospital than in the home, and I know from special investigations that sepsis—e.g., mastitis—may manifest itself after the patient leaves hospital. While the introduction of sepsis is often unavoidable, its spread is the most formidable problem which any epidemiologist can tackle. Much concerted and highly technical research into staphylococcal infections has been urged and is long overdue. Despite the fact that the presence of sepsis in the local hospital has been openly announced whenever it arose, there has never been any falling off in the clamour for admission to hospital.

The statement that local authorities think only in terms of institutions and clinics and that environmental factors are ignored is untrue. The local authority is very much concerned with environment (one of its major functions—and worries), but until recently it had little to do with practitioner services, although it had pioneered such adjuncts as ante-natal and child welfare services. That the practitioner realizes their importance since he has been actively associated in a local authority scheme is admitted—somewhat naively—by the authors, who state: "Under the Maternity Services Act the family doctor has already realized that the more careful and skilful his ante-natal examination is the less trouble he has at the confinement." I would also remind the authors that their domiciliary scheme was prepared by the local authority under the Maternity Services (Scotland) Act, 1937, and that it is very much the concern of the local authority that it should function properly. The public is very sensitive to deficiencies in the social services, and the medical officer of health who has prepared and integrated the domiciliary scheme with his other services must correct any maladjustment. Failure to do so is reflected in the results, of which the best index is the infantile mortality rate.

Success, as the authors say, depends on team-work: the midwife, the doctor, the obstetrician, the hospital, the health visitor, the clinics, and also the paediatrician. The authors would arrogate the chief role to the doctor, as is his right as family doctor, but, generally speaking, I would say that he has forfeited his right. In urban areas, at any rate, the family doctor in the old sense—the authors' sense—has almost ceased to exist. He is no longer the self-reliant man his predecessor was, nor is it in his own interests or that of his patients that he should be. Unhappily he has permitted, *inter alia*, what should normally be general practice to become a specialty.

Midwifery is time-consuming and relatively unprofitable. As trained midwives became more common the practitioner allowed her to occupy his seat at " the bedside of the woman in labour," to quote the authors, while he went elsewhere. Even under the domiciliary scheme the 1:4 ratio of expected attendance by doctors at confinements has been found to be much too optimistic. How often does one see practices advertised with a list of their desirable features, including " no midwifery " ? As a result the burden of real midwifery has had to be shouldered by the midwives and by the hospitals. Many practitioners are loath to adopt what I have referred to as adjuncts of midwifery, and in some areas the operation of the domiciliary scheme was held up because practitioners objected to calling in an obstetrician. I, personally, favour domiciliary midwifery conducted by the family doctor who knows his job, and I have been fortunate in having practitioner colleagues of the type suggested by the authors—men whose help and judgment have been freely involved and given in the absence of the obstetrician. They constitute a minority of the profession, however, and few are under 50 years of age. The front-line unit in the home and in the hospital is undoubtedly the midwife, and too often it is she who must decide when to initiate action involving the whole team. In England the general practitioner has almost dropped out of the team altogether, and, statistically at least, the results there are better than in Scotland.

I would endorse what I would call tendencies rather than faults imputed by the authors : in the midwife—a reluctance to send for the doctor ; in the doctor—a reluctance to be sent for (not mentioned by the authors); in the less experienced obstetrician—a tendency to dramatize and overtreat; in the hospital—a disinclination to recognize sepsis as such and to establish early bacteriological diagnosis ; and, finally, to return to the doctor—a somewhat casual regard for the anatomy of parts to be sutured.

In conclusion I would refer to the authors' statement that " in the proposed National Health Service the maternity services would not be under the direction of the local authority." That part of the maternity services of especial interest to the author —namely, domiciliary midwifery—*is* to remain with the local authority. The very necessary adjunct, the municipal maternity hospital, may go to an *ad hoc* authority, the Hospital Board, while no one knows whether the obstetrician remains to advise the practitioner without having beds at his disposal or whether he shuts himself up in the hospital. Doubtless this disintegration will be glossed over by reference to " liaison " and " the closest possible co-operation."—I am, etc.,

James R. W. Hay,
Kirkcaldy. Medical Officer of Health.

Sir,—In reply to the article (Sept. 1, p. 294) by Drs. D. Dale Logan and E. K. MacKenzie I should like to make the following observations:

In any large maternity hospital the maternal mortality for " emergency " cases is many times higher than for " booked " cases—i.e., mothers looked after from early pregnancy by the specialist have a much lower mortality in childbirth than those who are not.

Apart altogether from the question of the skill and experience of the accoucheur, what facilities are at the disposal of the general practitioner doing midwifery in the home when something goes wrong? How many carry a blood bank with grouping sera or even plasma? Drs. Logan and MacKenzie will admit that some cases at least of post-partum haemorrhage are not due to a mismanaged third stage.

Why is it that we obstetricians cannot but note that cases of " failed forceps "—commonly due to an incompletely dilated cervix—always come in from outside and never occur in hospital?

Why is it that in any large maternity hospital each year there are a number of cases admitted so far advanced in obstructed labour that the life of the baby is lost and that of the mother endangered and in some cases lost also?

Caesarean section has been proved to give the best results for mother and child in major degrees of placenta praevia, and the time to perform the operation is before the woman becomes exsanguinated. I have rarely seen exsanguination in a " booked " case which turned out to be placenta praevia, but I cannot say the same of the " emergencies." These few instances—and many others could be quoted—have to be explained.

I have many times been called out with the mobile resuscitation unit and have found parturients *in extremis*—this state of affairs being due not to any lack of conscientiousness on the part of the doctor but (*a*) to his lack of training in obstetrics, and (*b*) to the lack of facilities at his disposal. Until such time as all medical men practising obstetrics are trained in the art such a position will obtain.—I am, etc.,

Sheffield. D. C. Wiseman.

Sir,—Judging from the recent report of the Royal College of Obstetricians and Gynaecologists, suggesting a " specialist midwifery service," and from the very practical article on domiciliary midwifery and the family doctor (Sept. 1, p. 294), there appear to be two schools of thought on the creation of a sound midwifery service for the country.

Under the circumstances a commission composed of obstetricians and G.P.s should be set up to formulate a plan for an efficient type of midwifery service which would be satisfactory to both branches of the profession. Neither a specialist midwifery service nor a domiciliary one would be likely to solve the problem, as the first would appear to be rather an extravagant measure for the whole country, and the second might fail in the treatment of abnormal cases. The formation of such a service should be based on the treatment requirements of normal and abnormal cases rather than on the formation of a new specialist branch of the profession.—I am, etc.,

Freshwater, I.O.W. Carlisle Kelly.

Anaesthetic Risks

Sir,—Anaesthetists and surgeons will be grateful to Major Kremer for publishing the description of seven cases of meningitis following spinal analgesia (Sept. 8, p. 309). This report is really helpful as a guide to other practitioners who are anxious to assess the risks and advantages of various forms of anaesthesia and analgesia.

There has been a tendency of recent years for anaesthetists and surgeons to abandon the use of well-tried and approved methods of inhalation anaesthesia, and to adopt other techniques the dangers of which have not been properly understood. We have to a large extent banished chloroform from our theatres, and opened the doors wide to other devils worse than the first. The alarming increase in the incidence of anaesthetic mortality and morbidity shows us that new methods are not necessarily better methods.

After the publication of Major Kremer's report, that of F. T. Evans (*Lancet*, 1945, 1, 115), and other evidence now available, it will clearly be quite unjustifiable to use spinal analgesia for operations which can be properly performed under inhalation anaesthesia. I think it will be generally agreed, now, that spinal analgesia should be administered only by the full-time professional anaesthetist, thoroughly familiar with the technique and aware of the many possible dangers.

While it is right that new agents, and new methods of administration, shall be constantly investigated, it would be much wiser, as Flagg says, if they were allowed to ripen on the tree of experience before being extensively used. It would be helpful if there were established special centres of research where new drugs and techniques could be thoroughly investigated and from which practitioners could receive information and advice. Prof. Macintosh has already established a pioneer centre at Oxford. Major Kremer has indeed done us a great service, and I very much hope that other practitioners will also tell us of their misfortunes as well as of their successes, so that each and every method of anaesthesia and analgesia may find its proper place in modern anaesthetic practice. Then, perhaps, we shall hear no more of those too numerous tragedies which have been so frequently associated with spinal analgesia of recent years.—I am, etc.,

New Barnet, Herts. JOHN ELAM.

Trilene Analgesia in General Practice

SIR,—One of the many problems the single-handed practitioner has to face is how to make minor surgical procedures painless. To incise abscesses and whitlows under local freezing with ethyl chloride is crude and far from painless, especially during the thawing-out stage. Local analgesia solves many problems, but is limited in its application, and distinctly dangerous for operations on the digits, and for circumcision, owing to the risk of gangrene, although M. Arnold (*S. Afr. med. J.*, 1943, **17**, 222) and M. A. Magid and O. S. Culp (*J. Urol.*, 1943, **50**, 508) have evolved a technique for the latter which appears to have overcome this risk, and their method has been confirmed by no less an authority than Hamilton Bailey. It is unsafe for dilating urethral strictures because of the risk of absorption.

Gas-and-air or gas-and-oxygen has the disadvantage of requiring expensive apparatus cumbersome to carry. The basal anaesthetics have the disadvantage of rendering the patient unconscious, which is not justified for many of these very minor procedures, and the rate of recovery depends upon the amount of drug used, the rate at which it is injected, and the exactness of the venous puncture; any or all of which factors may be misjudged, leaving a drowsy patient who is quite unable to depart from the surgery under his own volition in less than an hour. Trilene, I thought, would solve these difficulties; for not only is its analgesic property very high, but the rate of recovery is rapid—a most important desideratum. It remained, then, only to find the most suitable and inexpensive apparatus—an apparatus preferably which would allow variations in strength of mixture rather than a fixed-percentage apparatus, for the latter cannot be used for full anaesthesia, and it is obvious that the mixture which will suit a full-blooded navvy will not be suitable for a frail anaemic woman. I happened to read a description by Mr. G. Thompson, F.R.C.S., of Sydney, Australia (*Lancet*, 1942, **1**, 324), of how to modify Clover's or Hewitt's inhaler so as to be able to use it for all types of anaesthetic without its bag. So I got out my old Hewitt, which had not been used for many years (the bag of which had perished), and sent it to A. Chas. King, Ltd., to make the necessary alterations. These are an inspiratory valve at the external end of the bore, and an expiratory valve on the face-piece. I had the inspiratory valve made detachable so that the inhaler could revert to its original design (the expiratory valve can be closed). Incidentally, it is a useful piece of apparatus, which, with a double bag and mixing-chamber attachment, can be used to give gas, oxygen, trilene, or ether sequence. The only occasion on which I tried ether in this modified inhaler—to suture a perineum—I failed to induce anaesthesia.

My practice is to put 1 oz. of trilene or less into the inhaler and begin steady induction (too rapid induction has been reported to cause various cardiac irregularities), having carefully explained to the patient that he is to have complete control of the apparatus, and to breathe evenly and slowly as if falling asleep. As soon as the analgesic stage is reached, which is estimated by pinching or pricking the patient's arm, he is given the inhaler to hold and told to continue breathing. All the time I keep up a slow monotonous conversation by way of encouragement and to get the patient to relax. It is important that there should be an atmosphere of calmness with no distracting noises. I have given no premedication, but I believe that a preliminary small dose of one of the barbiturates, or even bromide or aspirin, an hour or more beforehand would increase the effect. The patient is told to lift the face-piece off the face during the non-painful procedures (tying the knots, threading the needle, changing the bougie, etc.), and then is allowed to take five to ten inhalations of the anaesthetic before the operation is continued.

Though my cases are limited in number I have not had any cause for alarm or even adverse symptoms. I have used this method for incising whitlows, passing bougies, catheterization, and, in fact, for any painful procedure. I have also used it in midwifery and for suturing the perineum, but in these cases I have allowed the midwife to increase the strength up to loss of consciousness, interrupting the inhalation during the non-painful manipulations. For circumcision in infants I use a few drops of trilene on a piece of gauze laid over the baby's face, and wait a few moments for crying to cease and automatic breathing to begin before snipping off the prepuce. As this is the only painful part of the operation, no more anaesthetic is given.

All patients are in the recumbent position on the examination couch, and are so kept while I put away my instruments and clear up the mess. Then they are made to sit on the couch for a few moments before putting on tie, collar, etc. It is hardly necessary to say that dentures and all tight clothing are removed as in any other anaesthetic procedure, and no female is put through this process without a relative or friend of hers being present throughout the whole procedure.

Although the success of this method is largely due to the marked analgesic properties of trilene, there would appear to be some additional factor, which is probably a conversion of passive receptiveness for anticipated pain, which causes rigidity, into active co-operation, with resulting relaxation—rather like the inhibition of the reaction to one stimulus which can be brought about by the imposition of a more powerful or more distracting stimulus; or, again, like the part of the mechanism of the Jendrássik reinforcement of the knee-jerk which diverts the attention. For, as one patient (a case of urethral stricture) remarked, he had been much too concentrated on breathing into the inhaler to pay any attention to anything that I was doing.—I am, etc.,

Keighley. WRIGHT LAMBERT.

? Abuse of Sulphathiazole

SIR,—Like Dr. E. Brauer (Sept. 8, p. 333) I have often wondered at the frequent use of sulphapyridine and sulphathiazole in infections where sulphanilamide is effective. This particularly applies to streptococcal infections of the throat and *B. coli* infections of the urinary tract. Sulphanilamide is both cheaper and less toxic.

My own experience with sulphapyridine and sulphathiazole, though, is that sulphapyridine is not only very much more unpleasant but more toxic. In fact I foresee the not-far-distant day when the magic 693 of yesterday will not be used.—I am, etc.,

Bungay, Suffolk. P. G. LEVICK.

Air Embolism

SIR,—The report by Dr. P. H. Dalgleish of two cases of air embolism following artificial pneumothorax refills (Aug. 25, p. 256) prompts me to send you the following account of what such an occurrence may mean to the patient himself, given to me by a man recently discharged from sanatorium. It was so striking that I had it recorded verbatim.

> "It was my turn next for a refill, and I went into the treatment room with a sinking feeling. I usually felt like this beforehand, probably the dread of a needle being pushed in a tender spot. I stripped off, got up on to the couch, and put myself in the position the doctor liked to have me. He then felt for a likely spot in which to put the needle. He marks it with iodine, and then turns to prepare a 'local.' Although it was my 8th or 9th refill I still had 'locals,' because, so I understood, my A.P. was a poor one, due to what the doctor called 'frightful adhesions.'
>
> The 'local' finished he turns to the sister saying he wants the longest induction needle she can find. He selects one, remarking as he always did on the poor condition of the points. The needle goes in, and I jump a little; I always did; to me it felt as if it was going through something it should not have done. It wasn't a pain but a dull ache for the fraction of a second. The air tube is fastened and the doctor sits on his little stool with the apparatus in front of him. I was not feeling myself, but I was able to watch the coloured

liquid in the 'U' tube. I knew that if I saw that bobbing up and down everything would be right. But no, it wouldn't move, and then all at once I started to feel strange. I felt frightened and wriggled about. The doctor says, 'What's the matter?' I opened my mouth to try to tell him I felt funny, but no distinct words would come out, just jumbled-up babbling. He pulls the needle out very quickly. I'm rolled from my left side on to my back. By this time the feeling seemed to have gone completely out of my body, and my sight had, too, apparently gone. It was as if I was in a white fog.

I felt something being forced between my lips, and in the distance I could hear someone saying: 'Swallow it, swallow it.' But this didn't mean a thing to me; I could feel it oozing out of my mouth again, and I could do nothing to stop it. By now I did not care much. My breathing was quite normal, but my heart I could feel beating at a terrible rate. The doctor was now standing by me, and it was not until many minutes had passed that I realized he was holding my wrist. This went on for some considerable time. Now he said: 'Grip my hand,' and I felt his hand hold my right. I managed to grip it slightly. 'Now lift your right leg.' Yes, I could move that. 'Now your left leg.' But that will not budge. He tried to make me grip his hand with my left, but that also will not move; in fact, I could hardly tell his hand was touching me.

I could hear a lot of rushing about, and I found myself suddenly surrounded by hot-water bottles. During this time there was much talking, but it always seemed so far off, until I heard someone say 'It's brandy, try and swallow it'; but it was given to me in drops, and apparently this went down without much effort; anyway I couldn't feel it running from my lips. I was left alone for some considerable time after this, and I tried to distinguish things in the treatment room, but the only thing I could see was something white, which I took to be a nurse's cap. Now the sister brings in some coffee, and, raising my head a little, holds the cup to my lips and I manage to swallow some of this. She tells me the porters are bringing a stretcher along and they will carry me back to my bed. This duly arrives, and after some considerable trouble I'm placed upon it and am taken to my room and put to bed. My pyjamas had been torn in transit, and I decided I was well enough to change them, if my room mate got them out of the drawer, which he did. But no, I had not sufficient control over my hands, and in the end my 'cubie' had to do it. My sight by this time was coming back, but everything was upside down, so I thought the best thing to do was to try and sleep. Incidentally, I had been in the treatment room 1¼ hours.

About 4 p.m. the medical superintendent came round and wanted to know all about it, but although I tried hard to speak my words kept getting mixed up, and so I gave it up. 'These little things do happen, you know,' he said, 'and we cannot continue with your A.P., but anyway you will get on just as well without it.' The next day two or three fellows who had troublesome A.P.s were told it was far too dangerous to continue with theirs."

He made a complete recovery and is to-day alive, well, and working.—I am, etc.,

BRIAN C. THOMPSON,
Tuberculosis Officer,
Middlesex County Council.

March Fracture

SIR,—In answer to my question "What are the M.O.s doing about the evils of stamping?" your correspondent "Pedes Plani Dolentesque" replies: "Nothing because there is nothing to be done." His reply also shows that the M.O.s of the Brigade of Guards are incapable of exerting their authority in a matter they consider harmful to the men under their medical care. Some men in other branches of the Service are not so complacent and carry out the instructions of the drill book in a satisfactory manner. On the other hand, drill sergeants are teaching men to stamp and even to "smash the concrete" in doing so, and with harmful results. Stamping being an "integral part of the Brigade particularly" sets a bad example of want of discipline to the rest of the Army. It is a pity because it is a harmful, inelegant prancing about by over-drilled guardsmen.—I am, etc.,

Stanmore. G. LENTHAL CHEATLE.

Marching on Rubber

SIR,—I have no doubt but that the Army authorities have considered the issue of rubber-heeled ammunition boots to the soldier instead of the present iron-shod variety, and that only wartime scarcity of natural or synthetic rubber prevented its adoption.

All American Army soldiers are issued with rubber-heeled boots. I discussed the subject with some of them just before D Day, and they assured me that they can do the longest marches without foot fatigue or blisters. The particularly annoying blister around the edge of the heel, so often produced by long marches on hard roads when wearing iron-shod heels, is unknown to them. At that time I followed their example and had my marching boots converted to rubber heels, and have never had a blister since.

The effect on regimental foot drill following the adoption of rubber heels would be to make it comparatively silent—a rather revolutionary change. Whether the introduction would reduce the incidence of march fracture or not I cannot say, but it would most certainly add greatly to the foot-comfort of the soldier.—I am, etc.,

Edinburgh. I. G. CAMERON.

Milk and Adjectives

SIR,—The pros and cons of milk safety, purity, or cleanliness, are argued *ad nauseam*, till some readers must feel, "Why drink milk at all whatever the adjective?" If pure milk means only an unadulterated product, clean milk only one free from dirt, and safe milk one in which living disease germs do not flourish, cannot the public have such elementary virtues without highfalutin and meaningless names like "accredited" being attached to the article? As doctors must, more than ever before, be teachers in the brave new world, and as they do know more of tuberculosis, typhoid, etc., than other folk, it is well that Dr. Hawthorne should once again remind us that it is simple duty to our patients in every house we enter to assure ourselves that no one is being slowly and deliberately poisoned by the consumption of milk that is *unsafe*.—I am, etc.,

Moor Park. ESTHER CARLING.

Climate and Civilization

SIR,—Dr. Kenneth Black's letter (Sept. 8, p. 334) raises an interesting point. Though it is true that tropical and subtropical climates do not appear able to maintain a high degree of civilization for any great length of time, yet it is equally true that throughout the ages they have acted as nurseries for culture. For the New World there were the Aztecs in Mexico, the Incas in Peru, and the Mayas of Central America; in the Old World, to mention only a few, there was an advanced civilization at Mohenjo Daro, in India, at the same time as the civilizations of the Nile and the Euphrates were beginning to flourish. Subsequently, civilizations spread progressively westward to colder climates—Greece, Rome, Western Europe, and, finally, North America.

Many of these early races—e.g., the Mayas, Aztecs, and Greeks—originally came from colder climates, and the process seems to have started when the warmer and kinder climate gave more leisure for an originally strong stock to progress toward civilization. In subtropical and temperate climates I think it still remains open to question whether the ultimate and apparently inevitable enervation is directly due to the warmth of the climate or to the soft living produced by civilization itself.—I am, etc.,

Newbury. T. NORMAN.

Premedical Zoology

SIR,—Referring to the interesting article by Abercrombie and Johnson on this subject (Aug. 25, p. 262), may I suggest an important illustration of the principle of giving preference to those aspects of zoology that have a human relationship. The morphology and kinetics of quadruped, monkey, ape, and man might form the groundwork for studying the maintenance of posture and good skeletal form in the human being. Posture maintenance in the quadruped is a very different problem from that in the monkey and ape; and the ape differs from completely orthograde man largely in the extent to which the arms are used for suspension and support of the body weight. Not that man's orthograde nature should be made an excuse for his greater susceptibility to postural degeneration; but we need to give much greater medical attention to the subject. In accordance with another principle recommended by Abercrombie and Johnson, this zoological approach should be co-ordinated with the subsequent study of postural orthopaedics, which it is hoped will at last be incorporated in standard medical education. Up to the present medicine has sadly neglected the everyday mechanics of human physiology.—I am, etc.,

Birmingham. E. H. WILKINS, M.B., D.P.H.

Remissions in Disseminated Sclerosis

SIR,—While remissions are a well-known feature of disseminated sclerosis it is rarely that one sees reports of individual cases of prolonged remission or of a series of such, giving one an average idea of what can and does happen to many cases of this disease. The following account, therefore, of a case in which diplopia was the only subjective symptom and absent abdominal reflexes the only objective sign, and in which there has been a remission for 13 years, may be of interest.

Mr. X., aged 26, came in 1932 complaining of slight double vision only that morning. He felt perfectly well otherwise and there was nothing of interest in the history. Examination showed only absent abdominal reflexes. His vision was slightly blurred, but 6/6 both eyes; fundi normal, no ocular palsy noted. The visual disturbance had disappeared in 12 hours. Blood Wassermann was negative. The late W. Adie saw him on the next day, and reported that he could obtain just the slightest flicker in the abdominal reflexes and nothing else. He dubbed him "D.S. suspect," but said, "I am afraid further troubles are inevitable."

The patient returned for a quite trivial complaint in 1945, when he reported that he had had no further trouble. On examination the only sign was still absent abdominal reflexes. Knee-jerks equal and active, no Rombergism, plantar reflexes flexor. His fundi showed some temporal pallor, more marked in the left eye.

It is always a difficult problem to give any prognosis in such cases and, as Walshe[1] says, "to cloud with gloomy apprehensions the life of a young subject who may have many years of normal life before him demands careful thought." The patient whose case is quoted above had recently married. Should one have been justified in advising him against marriage? I temporized by stating that in 13 years, so far as one could judge, there had been no progression of the disease.

The incidence of disseminated sclerosis in the Forces during the present war would be of the greatest value and interest. I had recently seen three cases in which no previous symptoms had been noted before Army training. Here the question arises as to how fatigue, both mental and physical, can and does precipitate crises in this disease. One therefore wonders if some clue could not be obtained, by the back door as it were, to the aetiology of the condition. What are the metabolic effects of fatigue, what the pathology or the biochemistry? What might fatigue so considered be capable of activating?

No evidence has been adduced for accepting the infective theory, or if so, as Collier[2] remarked, it behaves like no other infective process. Indeed, it resembles more the crisis of diabetes as precipitated by extraneous infections, although in disseminated sclerosis it may be not only febrile illnesses but injuries which disable the patient for a very short period only, or surgical interventions of all sorts not necessarily serious in themselves. I therefore feel that a more detailed study of the causation of exacerbations might lead to some progress in the knowledge of the aetiology at the moment completely unknown.—I am, etc.,

Highgate, N.6. W. LEES TEMPLETON.

Chronic Regional Ileitis

SIR,—I read with interest the case report of Drs. O. Wilson and T. D. Culbert (Sept. 8, p. 332). Characteristically their patient presented symptoms of intestinal obstruction relieved by a timely resection of the stenosed segment of gut. I think, however, the available evidence weighs heavily against their assumption that regional ileitis is a new disease and a rare one. They will find the report of a similar case to their own by Norman Moore (*Trans. path. Soc. London*, 1882–3, **34**, 112). In the ensuing fifty years papers by Braun (1909), Dalziel (1913), Moschowitz and Wilensky (1923), and Crohn *et al.* (1932) are milestones marking the gradual recognition of this lesion as a clinical entity. That of Crohn and his collaborators attracted so much attention that more than one thousand cases were reported from all parts of the world in the decade following its publication—a fact which dispels the concept of rarity. Even so, it is probable that some examples still escape record, because men hesitate to report cases of doubtful aetiology, preferring the cast-iron type of lesion to some *terra incognita*.

Regional ileitis, then, is an old disease with a new name—or names, for few morbid processes have acquired such a medley of synonyms, none of which has thrown light on its causation. As to this, Drs. Wilson and Culbert quote from an early paper of mine an opinion based on the naked-eye appearance of the lesion in the theatre. There it looks all over like an infective process, and I am still of the same opinion after further experience of it. But the authors of the present report regard some vitamin deficiency as the primary causal agent—in particular, vitamin C. This seems improbable in view of the sporadic incidence of regional ileitis. By analogy with a typical deficiency disease—e.g., pellagra—it should appear in epidemic form. Though far from rare, the lesion is not common enough to arouse suspicion of vitamin-lack in the community.

Lastly, the outline of a presumed case of acute ileitis treated solely by dietetic measures without abdominal exploration suggests that the precise diagnosis could be only a matter for conjecture. The resolution of a palpable mass during the administration of a daily dozen oranges raises some doubt whether this retrogression was truly *post hoc propter hoc*. Is it possible that the patient's "extraordinarily lax abdominal walls" had their counterpart in a similar laxity of her abdominal mesenteries, and that a self-reducing volvulus or intussusception accounted for the disappearance of the mass?—I am, etc.,

Ashton-under-Lyne. F. G. RALPHS.

The Filigree Operation

SIR,—Without entering into the merits or demerits of the filigree operation in the recent correspondence between Squad. Ldr. J. B. Kinmonth and Mr. W. Pickup Greenwood, I would like to mention that I published a case in the *B.M.J.* of April 12, 1924, under the title. "Repair of a Recurrent Inguinal Hernia by Means of a Gauze Filigree." I believe that this type of filigree inserted as described by me has many advantages over the metal filigree. I envy Mr. Greenwood his opportunity to have operated on 80 cases since 1938, in some of which I feel this method could have been used.—I am, etc.,

Durban, S. Africa. D. O'DONOVAN.

End-to-end Anastomosis in the Small Intestine

SIR,—I was very interested in Major J. Seton Pringle's description of end-to-end anastomosis of the small intestine (Aug. 25, p. 256). I do not know if his is the first record of the use of this method in the human subject, but some of your readers may be interested to know that this method was taught by J. G. Wright, F.R.C.V.S., Professor of Veterinary Surgery, University of Liverpool, some thirteen years ago when he was at the Royal Veterinary College, London.

I reported the successful use of this method in the dog in a communication to the *Veterinary Record* in 1939.—I am, etc.,

Basingstoke W. R. TURNBULL.

Doctors and the Social Trend

SIR,—What I thought when I read Dr. Shackleton Bailey's really admirable letter (Aug. 18, p. 235) has since been very aptly put by two other writers—namely, that Dr. Bailey has shown us the way out in one of the most constructive and understanding letters that has appeared in our *Journal*, and that it is a pity such clear thinking is not more common.

Only one statement in that letter needs modification—that no one can now fail to discern the signs of the times. Apparently there are a number, and some have since put their pens to paper. Dr. Duckworth, for instance (*Supplement*, Sept. 1, p. 55), tries to prove that the public gave no decided answer in favour of a whole-time National Health Service. He quotes Lord Quickswood in the *Sunday Times* in the argument that by proportional representation the Conservative and Liberal members together would have just outnumbered the Labour members. He makes the unjustifiable assumption that all the Liberals would be opposed to such a service. But in one of the main Liberal organs (*News Chronicle*, Sept. 7) their spokesman, A. J. Cummings (and who should know better than he?), states that in the main the Liberal vote "was a left vote." And since we are quoting peers, at the highest level, let me remind him of the statement of Lord Cranborne, Leader in the House of Lords of the Conservative Party—a party, incidentally, which opposed proportional representation. Lord Cranborne said (Lords, *Hansard*, col. 47 of Aug. 16): "Whatever our personal views, we should frankly recognize that these proposals were put before the country at the recent General Election, and that the people of this country, with full knowledge of these proposals, returned the Labour Party to power. The Government may fairly claim that they have a mandate to introduce these proposals. I believe that it would be wrong . . . for this House to oppose proposals which have been definitely put before the electorate. Moreover . . . it would be an error of the first water." This, coming from such a source, should be a warning to the B.M.A. not to commit mass hara-kiri. Furthermore, it seems safe to assume that if those disenfranchized by the hurried election, mostly industrial workers and members of the Forces, had been able to vote, the swing to the left would have been even more pronounced.

Dr. Harrower (Sept. 1, p. 302) is sure that "the medical profession, if united, can defy anything of which it does not approve." Supposing it were true, which it is not, that in that case we could act as dictator against the wish of the people, was the medical profession ever united? Far less so on these issues than on most. Is she aware, for instance, of the great extent of left sympathy among medical students, in the North, in the Midlands, and in London? They will become doctors during the present Government's term of office. Or of the very recent vote of the British Medical Students' Association on this point? Or of the fact that of the 13 medical M.P.s in the new Parliament 8 are members of the Socialist Medical Association? Or that a very able and respected member of our profession sits on the Executive Committee of the Communist Party—a party which includes a considerable number of doctors?

Compare all this writing on the wall with thought inside our profession at the time when many of us were still students, and we can better grasp the social trend among an ever-growing number of doctors at the present day—doctors, that is, who try to adjust their ideas of historical evolution in the same way that they strive to keep up to date with medical advances.

What worries me is how the Association is going to co-operate fairly and squarely with Mr. Bevan through the medium of leaders most of whom have already shown their hand as opposers of all but what Dr. Bailey so aptly calls "a Conservative filtrate of socialist doctrine." The public, it will be remembered, turned out of office, with no uncertain vote, and even in such a stronghold as Birmingham, most of these filtrate appeasers. They therefore have a clear field. But have we?—I am, etc.,

London. P. G. S. DAVIS.

SIR,—Dr. W. B. Pemberton (Sept. 1, p. 302), after going into the matter "with various sections of the community," has got down to brass tacks and decided that the minimum terms under which a "general practitioner of some years' standing" might accept State service include a salary of £1,250 a year with travelling expenses, and a pension of £500 a year at the age of 65. Though he does not say so, it is presumed from the context that this is the maximum salary to which a general practitioner may aspire.

Does Dr. Pemberton really think that the practitioner "of some years' standing," on duty 7 days a week and 24 hours a day, will be sufficiently remunerated by £1,250 a year? Does he forget that the pound to-day is equal in purchasing power to 8s. 4d. in 1914? How is he going to educate four children—i.e., send them to a public school and university? Perhaps he thinks that no medical practitioner should have any children, or if he does that they should attend a State school and that their education should end there. Then, again, is the pension of £500 a year after 65 (how many general practitioners will reach 65?) to cease with his death, and is his wife to live on the old-age pension should she survive him? One cannot but wonder regarding the type of man such financial prospects are going to attract into our profession.

The Goodenough report on medical schools recommends that the standard of training of medical students should be that for a university degree. How many parents who have themselves had a university education will advise their boys to undergo a hard training of six years' duration with such prospects at the end of it? I have not met a single medical man who will do so. Has anyone else? There is no doubt, however, that if the Government wants a cheap medical service it will get it and the men to work it. But it cannot have it cheap and good.

Whether the new service is a salaried one without any free choice of doctor, or whether it involves merely an extension of the panel system to the whole population with free choice retained, in my opinion matters little, provided remuneration is adequate and other terms and conditions of service fair. The terms outlined by Dr. Pemberton are grossly inadequate and are fair to no one, not even the patient.—I am, etc.,

London, W.C.1. F. J. BROWNE.

SIR,—Dr. Hugh Gainsborough's letter (Sept. 8, p. 344) aptly remarks how his years in the E.M.S. have taught him the pleasure of whole-time medical service. If a consultant of his standing comments on it, it will be echoed by a number of younger specialists in the E.M.S. and Forces who previously would have struggled to keep up appearances of a "successful consultant" for a number of years. How many medical research problems have been shelved, indefinitely, for the necessity of building up a private practice. It is the merit of the E.M.S. and of the men who created it to have supplied consultants and specialists to people and districts where from the private-practice point of view their permanent residence would not have been justified. Moreover, the E.M.S. has given the pattern for the new National Health Service. Dr. Gainsborough rightly calls for more understanding of inevitable social trends by the medical profession—or as it was said two thousand years ago: "Can ye not discern the signs of the times?" (Matt. xvi, 3).—I am, etc.,

Botleys Park. H. W. GILLESPIE.

SIR,—In the course of a letter on the prospective reorganization of the medical services Dr. N. P. Henderson says parenthetically that a full-time medical service has failed "to a large extent in Russia." What grounds are there for this statement? The most complete study on Russian medicine, that by H. Sigerist (*Socialised Medicine in the Soviet Union, 1937*), gives factual data which suggest that a full-time medical service has been exceedingly successful. The Anglo-American surgical mission which visited the Soviet Union last year hardly reported adversely, judging by the articles that appeared in your columns and elsewhere. Nor is the failure of Soviet medicine apparent in the sober and factual accounts that the most recent investigators, Prof. E. D. Adrian and Prof. Arnold Sorsby, contributed to *Nature* of Aug. 25. What is the evidence on which Dr. Henderson bases his opinion and what are his criteria of success and failure? Is his oracular pronouncement based on facts apparently exclusively in his possession or is it mere irresponsibility?—I am, etc.,

Highgate Hill, N.6. L. FIELDMAN.

A Plea for the Young Specialist

SIR,—It is generally agreed that there will be a shortage of specialists for some years, and that it will prove very difficult to fulfil in an efficient manner the demands which any National Health Service may make.

The hardship of the young medical officer in the Services who has specialist ambitions but who has been prevented from taking a higher qualification owing to the "exigencies of the Service" is also recognized. At present, if he has joined one of the Services in 1940 or 1941, but is only 29 years old, he is in the position that many months will elapse before he is demobilized. During his time in the Services he may have gained considerable specialist experience and may even have been graded as a specialist, but in competition with his civilian colleagues of the same age he will be at a serious disadvantage when the time comes for him to apply for some specialist appointment in civil life, as he will not possess the necessary higher degrees. Would not the following scheme provide one method of overcoming both these obstacles?

1. The scheme would be applicable only to medical officers who had been at least three years in one of the Services.

2. In both Home and Overseas Commands a list should be drawn up of those medical officers who wish to sit an examination for a higher degree. This degree must be of sufficient standing to give them an opportunity to apply for any specialist appointment which (we hope) will be advertised only when demobilization becomes more general.

3. The higher medical authorities of the Services and the Central Medical War Committee together would determine how many of these younger men were replaceable by civilian specialists, who would be called up for one of the Services.

4. Once this total had been determined, allocations would be made to the various Commands. In the event of an insufficient number of replacements being available for the demands of the scheme a ballot would be taken.

5. The successful medical officer would be allowed a three-months period of study leave on full pay and allowances. During this time he would be required to sit the recognized examination.

6. Should he be successful in his examination he would have the option of being placed in Class B and of securing demobilization. If he failed he would continue his Service career.

Surely now that hostilities are over the demands of the Services are not so great, and after an experience of nearly six years as an otologist in the Army I am convinced that it is these younger men who have been most severely penalized in their medical careers. The transfer to Class B of the candidate who passes the examination certainly places a premium on examination results, but that is inevitable. The fact that early demobilization can take place only by this means will prevent the scheme becoming a "racket." Once the successful candidate has been demobilized, every encouragement should be given him to take up a post such as a registrar in one of the larger hospitals under the Government rehabilitation scheme in order that he may widen his knowledge of his specialty beyond the rather restricted field that the Services give. Similarly, during his period of study leave no opportunity should be lost to visit the civilian hospitals.

Even if the medical officer is not successful he will have gained a lot, and will be more prepared to resit his examination when his turn comes to be demobilized with his proper group. Because of the number who may wish to take advantage of the scheme, it will probably be found that only one attempt at passing the examination can be allowed to each medical officer, but at any rate he has had a chance to catch up with his civilian colleagues.—I am, etc.,

Aberdeen. E. G. Collins.

Bitterness

Sir,—In the medical press of late there have been letters from Service doctors which savour of the bitterness many of them feel about their present circumstances and their future. In the Army there are some reasons for this, particularly between those who volunteered (T.A., S.R., and others) and those conscripted, and also towards young civilians who have served in the E.M.S. and private practice. Perhaps the lot of young doctors who volunteered and have spent all the war as battalion and field ambulance officers while their contemporaries stayed as civilians to gain some higher qualification and later entered the Army as specialists in a higher rank is worse than those of us who in middle age have lost our well-established practices. Let us hope that remedies will be found so that these grievous feelings may not be carried forward to spoil the team-work needed from our profession in the difficult play that lies ahead of us, for bitterness is bad and a hindrance.

Most of us who have been in the Services have gained much that outweighs material loss and even professional advancement. We have met some really fine men we would not have come across otherwise. Our consciences are quiet on the matter of what we thought was our duty. Many of us have been privileged to feel in times of military success and adversity that we were a small part of the national team on the field. Our casualties compared with the combatants have been relatively small in killed and wounded, and we have indeed to be thankful that the sea or six feet of African sand or European earth has not been the lot of most of us. Despite all the irritations and frustrations that I in common with most medical officers have felt during service, I know that I owe much to the Army. I may be accused of being more fortunate than the majority, for in 5 years and 11 months of service (mostly over-seas) I have had 2 years and 11 months first-class surgical work with excellent equipment. During the remaining 3 years such clinical work as I had to do touched rock-bottom with meagre equipment and under conditions that were unnecessarily squalorly. For 15 months my duties were concerned with P.T., games, and those of a company officer. However, even the doldrums of transit camps and troopships can be put to good use in writing papers, or even books, and in reading (congested humanity permitting).

Let us hope that those in charge of hospital and other appointments will do their utmost to sweeten the bitterness by giving a good chance, particularly, to the released M.O. whose patriotism and altruism led him to volunteer for the Services before he had taken the higher qualifications he had planned in peacetime. Also that public authorities may be sympathetic and find appropriate accommodation where the "released" doctor may live and practise.

On release from the Service it is, I think, considerably harder to resist bad feeling when unable to find accommodation in which to live and practise.

London. H. B. Stallard,
Major, R.A.M.C.(T.A.).

Medical Photography

Sir,—I have read with great interest the article on medical photography in hospital (Sept. 8, p. 328).

There is no doubt that in most hospitals throughout the country medical photography is done under the most difficult of conditions. Recently I have been conducting some investigations on the testing of the peripheral circulation by means of intravenous fluorescein. In order to keep a record of these cases it has been necessary to take photographs with kodachrome films or films of a like nature. In addition, in order that the photographs should be reproduced exactly an expert photographer is needed with a good camera and all the extra appliances which are required in the taking of a good film. Such conditions are impossible to obtain in a hospital these days. In carrying out the photography of my cases I was fortunate to have the collaboration of a local photographer. After explaining to him what was needed, he entered into the work with the greatest of enthusiasm.

I feel sure that an Institute of Medical Photography is urgently needed where photographers can be trained to carry out this expert work. These men could then be available to the hospital in the town where they reside. In addition, a photographic room should be available in every hospital, where electric fittings, lighting units, and all the extra requirements for good photography are at hand, and where the processing could be carried out.—I am, etc.,

London, W.1. Maurice Lee.

Banting Memorial Diabetic Convalescent Home

Sir,—The debt of life and health that the diabetic world owes to Banting's discovery of insulin is beyond words, and diabetics in this country want to recognize it adequately by a practical memorial. The Diabetic Association, a combination of lay patients and interested doctors, is planning to honour his memory by establishing a convalescent home, badly needed but so far non-existent, where diabetics leaving hospital after acute treatment can be fully restored to normal health by proper diet, insulin, and diabetic training. It will serve, too, as a holiday home for diabetic children.

This home must be started by voluntary effort. We have already collected £8,000, but we aim at a worthy memorial, and need £50,000. The people whose pleasure and duty it is to provide this money are obviously diabetics, especially the rich, who know the blessings of insulin for themselves or loved members of their families. It is difficult for us to get in touch with them, and there could be no better means of contact than the doctors who treat diabetics. We therefore beg, through the courtesy of your *Journal*, such doctors to acquaint their diabetic patients of this memorial scheme to Banting, and to urge them to support it handsomely. Subscribers should communicate with the Diabetic Association, 9, Manchester Square, London, W.1.—I am, etc.,

London, W.1. R. D. Lawrence,
Chairman.

Obituary

JAMES HENDRY, M.B., F.R.F.P.S., F.R.C.O.G.

We regret to announce that Prof. James Hendry, who held the Regius Chair of Midwifery at Glasgow University since 1943, died on Sept. 9 in his sixtieth year. He was chairman of the medical committee of the Scottish Advisory Committee to the Nuffield Provincial Hospitals Trust, and a member of the Medical Advisory Committee to the Secretary of State for Scotland. From 1927 to 1943 he was Muirhead Professor of Obstetrics and Gynaecology at Glasgow, and on his election to the Regius Chair he gave up private practice to become medical director of the Glasgow Royal Maternity and Women's Hospital.

James Hendry was born at Beith in Ayrshire on Sept. 25, 1885. He entered Glasgow University from Beith Academy as an arts student in 1903. After a distinguished career in science and medicine he graduated M.A., M.B., Ch.B., and B.Sc. in 1910, and then broadened his experience by a prolonged course of postgraduate study abroad. For two years he undertook research in Germany and Austria, and on returning to Glasgow in 1913 from the Clinique Tarnier in Paris received an appointment at the Royal Infirmary. When war broke out in August, 1914, Hendry was a captain in the University Contingent of the O.T.C., holding the post of adjutant for two years, and for this service was awarded the M.B.E. He served in France with the R.A.M.C. from 1916 until the end of the war, when he retired with the rank of major, and was appointed first assistant to the Muirhead Professor of Obstetrics and Gynaecology at Glasgow and resumed his work as operative surgeon and clinical teacher. Soon afterwards he became senior assistant physician to the Royal Maternity Hospital, and was promoted later to be chief obstetric surgeon there and chief gynaecological surgeon at the Royal Infirmary. He was elected F.R.F.P.S. in 1923.

Hendry had been a member of the Glasgow University Court since 1939, and undertook many administrative duties on behalf of the university. He was a Foundation Fellow and member of the original Council of the Royal College of Obstetricians and Gynaecologists, and was the sole representative of that branch of medicine on the Interdepartmental Committee on Medical Schools (the Goodenough Committee), which reported in 1944. His gift for teaching and administration marked him down for appointment to the Regius Chair two years ago. Hendry's capacity for work and eagerness to help in good causes were a byword in Glasgow and far beyond. His mind was constantly occupied with the problems of undergraduate and postgraduate teaching. When not in committee, in the classroom, or in the operating theatre, or examining candidates, he would visit Edinburgh for work on behalf of the Central Midwives Board for Scotland, of which he was deputy chairman, or would travel by night to London to give his services in wider spheres.

Hendry joined the B.M.A. in 1913, and held office as vice-president of the Section of Obstetrics and Gynaecology at the Annual Meetings in 1923 and 1939. He examined for the Universities of Aberdeen, Durham, and Edinburgh, and for Queen's University, Belfast, and he was joint author of *Midwifery Notes for Students* (1920), and of the well-known *Combined Textbook of Obstetrics and Gynaecology*, first published in 1923 and now in its third edition. He had been president of the Obstetrical Societies of Edinburgh and of Glasgow.

We are indebted to Mr. EARDLEY HOLLAND, P.R.C.O.G., for the following appreciation:

James Hendry was an important man in British medicine, and was one of the rare people who might be said with truth to have no duplicate. It is uncommon to combine great clinical skill with academic gifts and powers of exposition, in speech and writing, of a high order. This was the mingling of qualities that Hendry possessed, and when the proper authorities in Glasgow decided that the largest maternity hospital in Britain—the "Glasgow Royal"—should be in the clinical charge of one "chief," who should also be the director of teaching in the university, Hendry was there, ready and fully armed at all points. Whether he was made for the post or the post for him must remain a matter for conjecture. It was a radical change from the old tradition of hospital staffing, and it was perhaps fitting that the trial should be in the country of the see who worshipped the leadership principle. Hendry quickly won the affection of his junior colleagues and became the beloved chief of this immense hospital and teaching unit. He gave valuable help in working out for the Department of Health for Scotland the detail of the improved maternity service embodied in the Maternity Services (Scotland) Act, 1937; he was also a member of the scientific advisory committee that published the report in 1943 on infant mortality in Scotland. Hendry was chosen to be the representative fo his branch of medicine on that small but highly important body the Interdepartmental Committee on Medical Schools which, under the chairmanship of Sir William Goodenough, reported so resoundingly in 1944. The many long meetings in London, spread over the two most difficult travelling years of the war, in addition to heavy duties to patients and students in Glasgow, must have been a trial of strength even to so robust and equable a man as Hendry. His untimely death at a time when the teaching and practice of medicine are alike in the melting-pot is a sad loss to British, especially Scottish, medicine, and most of all to the City and University of Glasgow

Dr. R. A. LENNIE, chief obstetric surgeon, Glasgow Roya Maternity and Women's Hospital, writes:

In the death of James Hendry Scotland has lost one of her preeminent medical men and the world of obstetrics has suffered a grievous loss. His forceful personality was dedicated to the betterment of obstetric teaching and practice, and he was unswerving in his aims to this end. His energy and capacity for work were prodigious and caused amazement to his friends. Apart from his professional duties, which were his first interest and concern, his vast experience and well-balanced judgment were recognized by his country and his university, both of which valued his advice and guidance in matters pertaining to his specialty. He was held in the highest respect and regard by his students and house-surgeons, many of whom may well bless the day they came under his influence and teaching. Unsparing of himself, he expected a high standard of efficiency and sense of duty from his juniors, but his apparent austerity was tempered with an underlying friendliness.

Throughout the war years his sense of pride in having all three sons serving was leavened with the knowledge that one was wounded and a prisoner. During the period of uncertainty his suffering and anxiety were bravely masked, and he carried out his multitudinous duties with outward fortitude. This was typical of James Hendry and it was fitting that his last months of life were brightened by a happy reunion.

His main interests lay in his profession, and any leisure moments were devoted to problems of teaching and the furtherance of his ideals of an adequate maternity service. He thus had little time for recreation and seldom seemed to relax. He thoroughly enjoyed, however, the good fellowship and social attractions of an obstetric congress or a meeting of the Gynaecological Visiting Society. With a strong sense of humour he was a good raconteur, and was never seen to better advantage than at a dinner with his intimates and fellow-obstetricians from further afield. He had many friends throughout the kingdom, and many will mourn the passing of Jimmy Hendry. As his colleague in hospital over many years, I shall always remember a friendship which ripened as it endured. He has died at the peak of his power, and the country can ill afford to lose a man of his calibre and attainments, while so many new issues are at stake. He leaves a memory which will be an inspiration to those who follow him.

Dr. JAMES SMITH McCRACKEN, who died at Melrose on Feb. 22, was in his 84th year. He was in practice in Newcastle-upon-Tyne for nearly 40 years. One of a family of eight, he was the second son of James McCracken, farmer, of Altimeg, Ayrshire, and Blackhalls and Greenleighton, Northumberland. His father was a noted breeder of black-face sheep, and he was descended from a long line of Galloway farmers. A noted Covenanter, Matthew MacIlwraith, of Colmonel, was among his ancestors. No direct ancestor was a physician, but a collateral, Gilbert McCracken, took his M.D. at Edinburgh University in 1802. J. S. McCracken was educated at George Watson's College, Edinburgh, and Edinburgh University, where he spent a year in the Faculty of Arts before studying medicine; he graduated M.B., C.M. in 1885 and M.D. in 1906. He was physician and later consulting physician to the Fleming Memorial Hospital for Sick Children and visiting physician to the Newcastle Dispensary. He had a wide knowledge of English literature and a deep appreciation of poetry, and had acquired an extensive library during the course of his life and was something of a bibliophile. He had many fine editions, and format was of great importance to him, but he could quote appositely from a great range of poets, and there were many authors whose works he seemed to know in their entirety. He collected everything, from china and stamps to flint arrowheads and prints. Of engravings, etchings, and mezzotints he had a specialized knowledge and a remarkable collection. He had a nice discrimination, and early in life he came to appreciate the great merit of Samuel Palmer's work. His literary and artistic tastes naturally influenced his approach to medicine: he was always original, and no textbook explanation of disease which ran counter to the clinical facts ever influenced him in making a diagnosis. As a diagnostician of the old school—the school which had perforce to dispense with most of the laboratory aids—he was supreme, and his approach to a problem was always through physiology. He was essentially the family physician, though he was often called on as a consultant, especially in the case of children, and was a first-class psychologist. He was scarcely influenced at all by the modern school of psychopathology, but a wide knowledge of literature and sympathetic observation of his patients gave him the requisite background of knowledge. Mrs. McCracken survives him. He had four sons, of whom three are members of the medical profession and one is the present M.O.H. for Newcastle. Three of his sons were on active service throughout the war of 1914–18; they all held combatant commissions. In the recent war two sons returned to the Army. One served with distinction as D.A.D.M.S. of the 50th Division in France at the Dunkirk evacuation and later commanded a field ambulance in the Western Desert. One son, Lieut.-Col. Angus M. McCracken, D.S.O., *M.C.*, died of wounds received while commanding a field regiment of the Royal Artillery at Mount Camino in Italy.

We regret to announce the death on Sept. 5 of Dr. **Harold Ernest Watkins**, of Newton-le-Willows, Lancashire, a past chairman of the St. Helens Division of the B.M.A. Son of John W. Watkins, M.D., he was born at Newton-le-Willows on May 30, 1868, and from Manchester Grammar School went to study for the medical profession at Owens College. After qualifying M.R.C.S., L.R.C.P. in 1889, he served as house-surgeon at the Manchester Royal Infirmary and medical officer to the Liverpool Farm School. He returned to his native place and became part-time M.O.H. to the Newton-in-Makerfield Urban District Council and medical superintendent of the isolation hospital and the maternity and child welfare clinics. Dr. Watkins had been for some years district surgeon to the L.M.S. Railway, and during the war of 1914–18 was medical officer to the Garswood Hall Military Hospital. After his retirement he continued to take a close interest in the work of the Newton-le-Willows War Memorial Hospital.

Dr. **William Thomas**, of Larkhall Rise, Clapham, died in Westminster Hospital on Sept. 7, aged 57. A student of St. Thomas's Hospital, he took the B.Sc.Lond. (with first-class honours in chemistry) in 1907, and after qualifying in 1915 proceeded M.B., B.S. in 1920. At St. Thomas's he won an entrance scholarship in natural science and the William Tite Scholarship, was demonstrator in chemistry and toxicology and in biology, resident anaesthetist, and casualty officer. During his years of practice at Clapham Dr. Thomas served as divisional surgeon to the Metropolitan Police, medical officer to the Post Office and the Board of Education, and medical officer to the Clapham General Dispensary. He had contributed to the *Transactions of the Chemical Society*, and published papers on road treatment in relation to fish life, diseases of trout, and pollution of streams. He joined the B.M.A. in 1920.

The following well-known medical men have died abroad: Prof. **Carl von Noorden**, from 1906 to 1913 director of the First Medical Clinic at Vienna, and Honorary Fellow of the Royal Society of Medicine, aged 86; Prof. **Otto Veraguth**, formerly director of the Institute for Physical Therapy at the University of Zürich and honorary president of the Swiss Neurological Society, aged 72; Prof. **Cesare Pezze**, an eminent cardiologist at Milan, aged 70; Dr. **Michel Léon Kindberg**, the French phthisiologist, a few days after his liberation from a concentration camp in Germany, aged 62; Prof. **Fritz Seiler**, director of the Medical Polyclinic at Berne; Geheimrat **Adolf Dieudonné**, for many years professor of serology at Munich and author of a classical textbook on immunity; Dr. **Otfried Müller**, formerly professor of internal medicine and director of the medical clinic at Tübingen University, author of an important work on capillary microscopy, aged 71; Prof. **Joseph Trumpp**, a Munich paediatrician, and one of the pioneers of infant welfare, aged 79; Prof. **Gustav Aschaffenburg**, formerly director of the psychiatric clinic at Cologne and founder of the *Monatsschrift für Kriminalpsychologie*; Dr. **Lucas Ayarragaray**, ex-secretary of the National Department of Hygiene, Buenos Aires, aged 82; and Dr. **Logan Clendening**, professor of clinical medicine and director of the Library and Museum of the History of Medicine at the University of Kansas, vice-president of the American Association of the History of Medicine, 1942–3.

Universities and Colleges

UNIVERSITY OF EDINBURGH

Edinburgh University Court has appointed S. W. Challinor, Ph.D., B.Sc., Department of Bacteriology, and Harry Culumbine, M.B., Ch.B., M.Sc., Lieut.-Col., R.A.M.C., Department of Materia Medica, to Imperial Chemical Industries Fellowships for a period of three years.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

The Harveian Oration on "Rheumatic Fever and Heart Disease" will be delivered by Dr. John Parkinson at the College, Pall Mall East, S.W., on Thursday, Oct. 18, at 3 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Monthly Dinners

Monthly subscription dinners in the College will be resumed in October for Fellows and Members of the College, members of the specialist associations linked with the College through the joint secretariat, and their guests. The dinners will be held on the Wednesday preceding the second Thursday of each month. The dates for this year are Oct. 10, Nov. 7, and Dec. 12. Applications should reach the Secretary of the College, Lincoln's Inn Fields, W.C.2, one week before the date of the dinner, accompanied by the remittance of one guinea for each ticket required.

The Services

Surg. Lieut. W. J. Winthrop, R.C.N.V.R., has been mentioned in dispatches posthumously for gallantry, determination, and devotion to duty in H.M.S. *Campbeltown* in the raid on St. Nazaire in March, 1942.

Temp. Surg. Lieut. J. A. Cosh, R.N.V.R., has been mentioned in dispatches for good services in rescue work and fire-fighting after an explosion in a merchant ship in the Port of Bari on April 9, 1945.

Surg. Lieut. A. P. B. Waind, D.S.C., R.N.V.R., has been mentioned in dispatches for courage and devotion to duty during the defence of Calais in 1940.

The following appointments have been announced in recognition of gallant and distinguished services in Italy:

O.B.E. (Military Division).—Lieut.-Cols. E. C. Janes and J. S. McCannel, R.C.A.M.C.

M.B.E. (Military Division).—Majors R. Ferguson, W. M. G. Wilson, W. S. Gilchrist, and C. C. Henneberg; Capt. C. H. Conway, R.C.A.M.C.

The following appointments and awards have been announced in recognition of gallant and distinguished services in Burma:

C.B.E. (Military Division).—Brig. (Temp.) G. J. V. Crosby, T.D., R.A.M.C.

O.B.E. (Military Division).—Col. (Temp.) T. F. M. Woods; Lieut.-Cols. (Temp.) P. B. Longden, A. J. Martin, C. E. Roberts, and R. N. Tattersall, R.A.M.C. Col. (Temp.) M. S. Purvis; Lieut. Cols. (Temp.) E. J. Crowe and J. M. MacF. Drew, I.M.S. Lieut.-Col. (Temp.) J. Wakeford, S.R.M.C.

M.B.E. (Military Division).—Lieut.-Col. (Acting) D. A. Langhorne; Majors (Temp.) J. C. Gregory and J. S. McCrae; Capts. H. C. Campbell and R. G. McWhinney; Capt. (Acting) F. E. Hall, R.A.M.C. Major (Temp.) C. F. Vieyra, I.M.S. Capt. (Temp.) D. Singh, I.A.M.C.

D.S.O.—Brig. (Temp.) A. N. T. Meneces, C.B.E., R.A.M.C.

M.C.—Capts. G. K. Beatty, T. A. Taylor, and J. Weir, R.A.M.C.

Freed in the Far East.—Lieut.-Col. J. W. Malcolm, O.B.E., M.C., Major W. M. Stewart, and Capt. G. A. F. R. Gibson, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Killed.—Capt. Albert Robson, R.A.M.C.

Wounded.—War Subs. Capts. T. P. Bliss, W. F. Carpenter, and R. E. Danckwerts, and Lieut. B. S. Crawford, R.A.M.C.

G. K. De Forest and L. M. Kerr (*Amer. J. med. Sci.*, 1945, **209**, 752) describe a small epidemic of streptococcal diseases among nurses attending a child with secondarily infected eczema who was a constant source of Type 14 haemolytic streptococci for many weeks. During a three-months period 50% of the nurses who attended the child became ill with sore throats or scarlet fever.

No. 35

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 1.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county) (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week)

Stillbirths	219	25	23			216	12	23		
Rate per 1,000 total births (including stillborn)			27					27		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Owing to movements of population, birth and death rates for Northern Ireland are still not available.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* there were 300 fewer notifications of measles than last week, 53 fewer of pneumonia, and 32 fewer of diphtheria; while the incidence of whooping-cough rose by 92, of dysentery by 54, and of scarlet fever by 19.

In Essex whooping-cough notifications rose by 36, and in Yorks West Riding they went up by 33. The incidence of measles was lowered throughout the country, except for a rise of 30 in Lancashire and an almost unchanged incidence in Kent and Essex, these three counties having 36% of the total notifications. In Lancashire diphtheria notifications rose by 20. Only 21 cases of acute pneumonia were notified in the combined areas of London and the south-east and south-west counties.

Increases in existing outbreaks of dysentery were responsible for the rise in notifications, no fresh outbreak being reported. The chief centres of infection were London 41, Lancashire 35, Surrey 26, Middlesex 16, Essex 15, Lincolnshire 12, Derbyshire 12, Yorks West Riding 11, Glamorganshire 11, Dorsetshire 10, Gloucestershire 10.

In *Scotland* dysentery notifications rose by 41. Other rises over last week's totals were scarlet fever 43, whooping-cough 26, measles 20, diphtheria 10. The increase in dysentery was mainly due to the cities of Edinburgh and Glasgow, where the cases rose respectively from 16 to 27 and from 27 to 43.

In *Eire* the incidence of diphtheria was almost doubled, increasing from 55 to 97 notifications. This disease is widespread, thirty-one registration areas being involved. A further large rise, of 39 cases, occurred in notifications of diarrhoea and enteritis; 113 of the total of 137 cases were recorded in Dublin C.B.

Week Ending September 8

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,151, whooping-cough 1,177, diphtheria 423, measles 538, acute pneumonia 268, cerebrospinal fever 25, dysentery 278, paratyphoid 12, typhoid 12, acute poliomyelitis 25.

Medical News

Dr. David Adler will give a lecture on "Plastic Surgery in Rio de Janeiro" in the British Council Theatre at 6, Hanover Street, London, W., on Tuesday, Sept. 25, at 4 p.m.

The 244th meeting of the Biochemical Society will be held in the Human Nutrition Research Unit of the Medical Research Council at the National Hospital for Diseases of the Nervous System, Queen Square, London, W.C., on Friday, Sept. 28, at 11 a.m.

The opening of the 104th session of the College of the Pharmaceutical Society of Great Britain and the presentation of prizes will be held at 17, Bloomsbury Square, W.C., on Wednesday, Oct. 3, at 3 o'clock. The President, Mr. James Clements Young, Ph.C., will give the inaugural sessional address.

At a meeting of the Society of Public Analysts and Other Analytical Chemists on Wednesday, Oct. 3, at 6.30 p.m. at the Chemical Society's Rooms, Burlington House, Piccadilly, W., Mr. Eric C. Wood, B.Sc., will read a paper on the theory of certain analytical procedures, with special reference to microbiological assays.

There will be a clinical meeting of the Medical Society of the L.C.C. Service on Thursday, Oct. 4, at 3 p.m. at Lewisham Hospital, S.E.13, when members of the staffs of Lewisham Hospital and St. Alfege's Hospital will demonstrate cases.

In January next, subject to certain formalities, the name of the Charity Organization Society (Denison House, 296, Vauxhall Bridge Road, S.W.1) is to be changed to the National Family Welfare Association. It will have affiliated to it family case-work agencies in most of the large centres of urban population. The first task of the representative council which is to be formed will be to assist, in close co-operation with the Marriage Guidance Council, in the formation of centres for the handling of domestic problems. The new name of the C.O.S. is intended to recognize how much of its real activities are concerned with family case-work.

The annual general meeting of the Association of Industrial Medical Officers will be held on Friday, Oct. 19, at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., at 2.30 p.m. The programme consists of private business followed by an address by Dr. J. C. Bridge, and by Mr. H. E. Griffiths, F.R.C.S., who will introduce a film on rehabilitation. After the meeting members will meet for dinner at the Trocadero Restaurant, 7 p.m. for 7.30 p.m., morning dress. Applications for dinner tickets, price £1 1s., to be made to Dr. W. Blood, Cadby Hall, Kensington, W.14.

The Royal New Zealand Society for the Health of Women and Children, otherwise known as the Plunket Society, has now reached its 28th year. It was founded by the late Sir F. Truby King, whose influence still persists and whose name is honoured year by year in the annual reports. The Dominion Council in its report for the year ended March 31, 1944 (Stone, Son and Co., Anzac Square, Dunedin), records that it has offered through New Zealand's representative in Washington to provide personnel, literature, and supplies for the relief and help of mothers and young children in war-ravaged and occupied countries. The Plunket Society has always regarded the educational side of its work as of the first importance, and grasps every opportunity to inform parents, school-girls, and the public generally on matters pertaining to the health of women and children. Many of its nurses are doing splendid work lecturing to groups of mothers on parentcraft, paying particular attention to right diet as one of the foundations of health.

More than 50 cases of tuberculosis have been discovered as the result of an x-ray survey of the inmates and employees at the San Quentin Penitentiary, U.S.A. The survey was conducted by the California Tuberculosis and Health Association with a 35-mm. x-ray unit, and an examination of the 3,415 films made showed that there were 7 cases of very advanced phthisis, 15 moderately advanced, and 32 minimal. In addition some 60 cases of abnormal cardiac conditions were detected.

The new wing of the Queen Victoria Hospital, East Grinstead, presented by the Canadian Government as a Canadian R.A.F. memorial, was formally handed over to the hospital on Sept. 5 by Mr. Frederick Hudd, Acting High Commissioner for Canada. The wing was built by Canadian engineers at a total cost of £60,000, and accommodates 50 patients.

At the last quarterly court of the Governors of the London Hospital it was announced that the London County Council has agreed that the hospital shall retain the annexe at Brentwood for five years from VE-Day. On Oct. 1 the number of beds in Whitechapel will be increased to 580, and it is hoped to add a further 70 later.

The King has granted authority to Andrew McDowall, M.B., F.R.C.S., to wear the Insignia of the Fourth Class (Civil Division) of the Order of Al Rafidain conferred upon him by the King of Iraq in recognition of valuable services rendered in his capacity of professor of surgery in the Royal Iraqi College of Medicine.

Lieut.-Col. T. H. Leggett, M.D., R.C.A.M.C.(R.), was recently appointed honorary medical adviser to the Commandery in Canada of the Venerable Order of the Hospital of St. John of Jerusalem. Dr. Leggett's home is in the city of Ottawa, and he is a past-president of the Canadian Medical Association.

Dr. Arthur George Southcombe, of the Palestine Government Hospital, Jerusalem, left estate in Great Britain valued at £20,685. He bequeathed £1,000 to St. Bartholomew's Hospital for the neurological department, and £1,000 to St. Bartholomew's Hospital Medical School.

The British Orthopaedic Association is meeting at the Royal College of Surgeons of England on Friday and Saturday, Oct. 26 and 27. Further information may be obtained from the secretary at 45, Lincoln's Inn Fields, London, W.C.2.

The issue of the *Schweizerische Medizinische Wochenschrift* for Aug. 25 is dedicated to Prof. Ernst Hagenbach, director of the surgical department of the Basle Children's Hospital, on the occasion of his 70th birthday.

The name of Dr. Archie Samuel Ellis, ship surgeon, s.s. *Tanda* (Eastern and Australian Steam Ship Company Ltd.), appears in a list of commendations for brave conduct when their ships encountered enemy ships, aircraft, submarines, or mines.

Statutory Rules and Orders, 1945, No. 1076, relating to handicapped pupils and school health service in England and Wales, has been issued for the Ministry of Education by H.M. Stationery Office, price 4d.

The King has appointed Leonard Anthony Paul Slinger, O.B.E., M.B., to be a Member of the Executive Council of the Island of Grenada.

Dr. P. S. Selwyn-Clarke, *M.C.*, F.R.C.P., Director of Medical Services, Hong Kong, has been appointed C.M.G. The appointment is to date from Jan. 15, 1945.

Dr. C. G. Kay Sharp, of Leeds, who has been a member of the council of the Royal Eye Hospital, London, for some time, was recently elected a vice-president of the hospital.

Prof. Gustav Roussy, member of the Institut de France and rector of Paris University, has succeeded the late Prof. Achard as general secretary of the Académie de Médecine.

Dr. C. H. Kellaway, F.R.S., has been elected Deputy Chairman of the Board of the Wellcome Foundation.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ANY QUESTIONS?

Ophthalmia Neonatorum

Q.—*Are 1% silver nitrate drops still the best routine prophylactic against ophthalmia neonatorum?*

A.—The prophylactic measures against ophthalmia neonatorum may be divided into pre-natal and post-natal. The importance of the pre-natal elimination of all vaginal infection cannot be stressed too much, nor are the precautions which should be taken during birth any less important. In particular the lids should be thoroughly cleansed *before the eyes are opened.* Where these details are thoroughly and conscientiously carried out the necessity for post-natal prophylaxis immediately the eyes are opened becomes less imperative. In such cases silver protein 10% should be sufficient. If there is any doubt about the condition of the vagina or the thoroughness of the cleansing of the eyes before they are opened, silver nitrate 1% should be used.

Precautions are necessary in the use of silver protein and silver nitrate. There have been substitutes for silver protein which have contained varying amounts of solvents to dissolve the active principle which are harmful to the eyes. Its use should not be prolonged. Silver nitrate is a powerful drug and should be employed with care. It tends to decompose into substances injurious to the eye on being kept too long and under the influence of air and light. The solution should be freshly made up every three weeks and kept in a yellow-coloured bottle with an efficient stopper, which should not be left out longer than is necessary.

Cerebral Diplegia

Q.—*A twin boy of 8 suffers from cerebral diplegia. He is quite intelligent, but has a spastic gait with spasticity of arms and hands. The main trouble which worries the parents is dysarthria. He can pronounce simple monosyllabic words and names, his hearing is unimpaired, and he understands and carries out so far as he is able all commands given him. What advice should one give the parents as to the best means of overcoming the speech difficulty?*

A.—Spasticity in cerebral diplegia may seriously affect the muscles of articulation, although in some children without any real intellectual impairment it is remarkable how well they may overcome the disability. What is worrying in this case is that speech at 8 years of age appears to be limited to monosyllables. It raises the question of what "quite intelligent" really means. A period of speech training by a speech therapist (see list published by Board of Medical Auxiliaries, B.M.A. House) would be well worth while, but the results will be disappointing unless intelligence is normal. This is a case for consultation at a children's hospital or with a children's physician.

Marriage and V.D.

Q.—*Should a woman insist before marriage on a negative Wassermann and, possibly, other reports from the man she is to marry? Many girls and women in the Services form attachments with men about whose antecedents they know nothing. It was different in the days when their brothers, or other relatives and friends, knew all that was worth knowing about any of the men they were likely to get acquainted with.*

A.—Many people will think that a woman should trust the man she proposes to marry, and it would seem that insistence by a prospective bride on an examination to exclude possible venereal disease is hardly likely to conduce to future marital felicity; much depends on how the man and woman regard these matters. Certain countries and States require a premarital examination, including a Wassermann or similar test, but British Service authorities have not considered such a procedure essential. In any event a negative W.R. does not exclude early communicable syphilis, whilst recent penicillin or sulphonamide therapy might vitiate any clinical or bacteriological examination for the detection of gonorrhoea (should the man desire to conceal it).

As to the statement that "it was different in the days when their brothers . . . knew," a prospective bridegroom would hardly be likely to tell his future brother-in-law that he was suffering from V.D.; people are usually somewhat reticent about these matters.

Paroxysmal Auricular Fibrillation

Q.—*A woman aged 59 has in the past 18 months had attacks of auricular fibrillation. The arrhythmia averages much less than 24 hours' duration. One attack ended with unconsciousness. She looked ashen-grey and appeared to be about to die, but was lifted on to her bed, and soon became conscious with a regular pulse. She has always had a slow pulse, 60 or under. So far the attacks have begun on waking in the morning after her normal night's rest.*

A.—The diagnosis in this case appears to be paroxysmal auricular fibrillation. If the attacks are coming frequently, it would be worth while to try quinidine sulphate gr. 3 or 4 three or four times a day, according to the effect and the tolerance of the patient.

Dispensing Schedule 4 Drugs

Q.—*I was recently informed that it was illegal for me to supply patients with phenobarbitone tablets or any other drugs in "Schedule 4," except in such quantities as might be requisite in emergency for a single dose. I find this statement difficult to believe.*

A.—There are no special limitations on the supply by medical practitioners to their patients of substances in the Fourth Schedule to the Poisons Rules. Such substances are also in the First Schedule to the Poisons Rules, and so far as the supply in question is concerned are subject only to the requirements for First Schedule substances which relate to labels, prescription book entries, and containers, and which are presumably already being observed by the questioner.

Meniere's Disease

Q.—*Can you suggest any treatment which will give some hope to a well-marked case of Ménière's disease in a man of 64? He dates the tinnitus and partial deafness 30 years back, when he was knocked out by a shell in Gallipoli. Attacks of vertigo began to appear about three years ago, and are now the most distressing symptoms. They are accompanied by double vision, entire loss of balance, and occasional vomiting. Attacks last from a few minutes to several hours.*

A.—If this is a true case of Ménière's disease, and the usual medical treatment of restricted fluids and salt-free diet, with sedatives, has failed to relieve, the best treatment is to destroy the affected labyrinth by alcohol injection.

Anti-gas Ointment No. 2

Q.—*What is the formula of anti-gas ointment No. 2? Can it be used for any purpose other than giving first-aid treatment to gas-burn cases?*

A.—The composition of anti-gas ointment No. 2, as disclosed by the Ministry of Home Security, is an active principle, chloramine-T, in a base of vanishing cream. This is a specific ointment designed for a special purpose (i.e., the treatment of burns of the skin by liquid mustard gas), and it is considered unwise to use it indiscriminately for other purposes. Experiments have been carried out in the Army with this ointment as a treatment for tinea cruris, but with little success, and the Ministry of Home Security has always discouraged its use among civilians for purposes other than anti-gas.

Heartburn and Cholecystitis

Q.—*A woman aged 45 suffers from chronic cholecystitis and severe and intractable heartburn. A fractional test meal reveals a marked hypochlorhydria, and the heartburn does not respond to acids or alkalis. How can the heartburn be explained and what should be the treatment?*

A.—It is assumed that other causes of burning pain near the ensiform cartilage have been excluded—hiatus hernia or peptic ulcer of the oesophagus, the latter usually associated with congenitally short oesophagus; and cardiac disorders, possibly psychogenic in origin. Two theories are held as to the causation of heartburn—the first that it is due to regurgitation of irritating material from the stomach into the oesophagus; the second that it is due to reflex spasm of the lower oesophagus. Reflex spasm is the most likely cause in chronic cholecystitis. For the dyspepsia of cholecystitis the usual remedies are olive oil before meals, and effervescent sodium phosphate 4 to 5 grammes before meals. If these remedies fail antispasmodics should be tried, such as a barbiturate plus belladonna, atropine, or trasentin. If there is any suspicion of a climacteric element in the symptoms, treatment with natural oestrogen or one of its analogues should be tried. Cholecystectomy has presumably been considered, though it must be confessed there is little assurance that it will relieve a reflex disturbance of this kind.

Diminished Vaginal Secretion after Pregnancy

Q.—*A young married woman with one child of 6 months is complaining of complete absence of vaginal secretion during intercourse. This has occurred only since she was about three months pregnant, and previous to this there was a copious secretion. She has normal sexual impulses. There is no obvious abnormality of vulva or vagina.*

A.—There is not likely to be any local abnormality in this case. The secretion liberated during coitus comes mainly from Bartholin's gland and is discharged as the result of sexual excitement. The amount secreted in any one individual is to a large extent dependent on the intensity of sex desire present at the time, and the diminished secretion in this case should be regarded as indicative of decreased sex urge—and that in spite of the alleged normal impulses. Diminished sex desire in woman during pregnancy and for a period after delivery, if not the rule, is extremely common. The very fact that the fundamental object of coitus is achieved, the awakening of mother love, the extra work and anxiety associated with looking after the child, etc., all play their part in effecting this change. But it is usually only a temporary one, and the partners of this marriage should be reassured accordingly. It is the husband who by patience allied with skilled love-play can do most to arouse the wife's sex-desire again to the full. Until he achieves that there is no reason why they should not use an artificial lubricant.

Psoriasis

Q.—*An officer has suffered from psoriasis for two years. The parts affected are the scalp, thighs, and glans. He has had four courses of psoriasis filtrate vaccine and several different local applications. There have been many relapses. The present treatment consists of local applications with liq. picis carbonis incorporated in them, and vitamin E orally. What is the latest treatment?*

A.—If by psoriasis the questioner believes he is dealing with a specific disease entity it must be said that the cause is unknown and no recent work has discovered any specific cure or "latest treatment." If, as seems probable, psoriasis is a constitutional reaction of the rheumatic diathesis, then success in treatment is more likely to follow consideration of climatic factors, of toxaemia (metabolic or infective), of endocrine and psychological influences. There is no indication for vitamin therapy in the absence of other signs of deficiency. One cannot talk of cure of a constitutional reaction. The same reaction has different causes at different times. What is necessary is an understanding of the nature of the problem—by the patient as much as by the physician—and control of the tendency to react will follow understanding.

Snake Venom for Epilepsy

Q.—*I have recently heard of a series of cases of idiopathic epilepsy treated with snake venom. (1) What is the rationale of this treatment? (2) Has its efficacy been satisfactorily proved? (3) Are there any dangers in its use? (4) Has it any advantages over the barbiturates?*

A.—The treatment of epilepsy with snake venom originated in South Africa out of the belief that accidental snake-bite sometimes had a good effect on various chronic disorders. Rattlesnake venom is used. Its efficacy has not been proved. In a few cases the writer has used it at the request of patients, but without benefit. Focal reactions at the site of injection are not uncommon, but there seems no danger in giving recognized doses. Not only has it no advantage over the barbiturates, but it appears to be ineffective.

Treatment of Bronchial Asthma

Q.—*Hypodermic injections of 100 mg. pethidine are advised in the symptomatic treatment of an acute attack of bronchial asthma. Are there any contraindications to this treatment in acute cases? Are frequent light applications of the cautery to the "asthmogenic area" of the nasal septum, and intratracheal injections of lipiodol, of any value?*

A.—Pethidine hydrochloride "has a morphine-like action, though it is more antispasmodic and less narcotic than the opium alkaloid." Both these actions are made use of in the treatment of an acute asthmatic attack—the antispasmodic and analgesic. But with the relief of the spasm and the abolition of the cough reflex and the lowered ciliary action there is a tendency for the sputum to accumulate in the lungs and for the patient to become blue and drown in his own sputum. Otherwise its toxic effects are uncommon and not serious, but there is some risk of addiction. It should be used only when adrenaline has failed.

Nasal cauterization has been advocated for many years, and at times it appears to act miraculously for a short time, but usually recurrent applications are necessary, with less and less effect.

Scibold in 1940 reported a high increase of the mortality rate of asthmatics in a 12-month period following the therapeutic administration of iodized oil.

Varicose Veins in the Elderly

Q.—*Is age any bar to the division and ligature of a varicose internal saphenous vein associated with eczema of the leg in an otherwise healthy woman of 73, and do you advise very early sitting up after the operation? There has not been any tendency to phlebitis, and there is only slight swelling of the leg above the ankle.*

A.—Ligature of the saphenous may be carried out, provided the patient is not obese and is young for her age of 73. The patient should be ambulatory from the day of the operation; this is more important even in older patients because of the risk of femoral thrombosis. If there is excessive phlebitis in the superficial veins following ligature and injections, it can easily be controlled, without interrupting the ambulatory nature of the treatment, by elastoplast and padding, as in the treatment of spontaneous superficial phlebitis.

Iodochlorhydroxyquinoline

Q.—*A patient aged 45 is used to taking iodochlorhydroxyquinoline for its good laxative effect. Is its long-continued use likely to cause any intestinal or other malignancy, and would the iodine content upset thyroid or other endocrine mechanism?*

A.—This substance is commonly prescribed as a treatment for amoebic dysentery, and it has no generally recognized action as a laxative. Its laxative action in this patient is probably peculiar to him. Its long-continued use is unlikely to produce any harmful effect. The tablets contain 0.25 g., and three tablets would be 0.75 g. This contains much less iodine than is present in 1 g. potassium iodide, which is administered three times daily for four weeks at a time in the treatment of syphilis without harmful effect.

A Tourniquet

Q.—*The G.P. frequently has to give intravenous injections, and usually there is no assistant present. A small tourniquet which could be quickly released by the patient when penetration of a vein has taken place would be an advantage. The usual type takes a long time to release, and sometimes the limb is shaken in the process. Is such a tourniquet available?*

A.—Most pathologists find it adequate to use a length of soft rubber tubing, size 2, internal diameter 4 mm. This is wound once round the arm and the free end looped underneath. It is easily released by pulling on the free end of the loop. Even less disturbance is caused by using a sphygmomanometer and releasing the pressure in the cuff by turning the milled screw when the vein is entered. No tourniquet superior to this is known to the writer.

INCOME TAX

Purchase of Practice

"X. A. X." was from January, 1943, to June 30, 1945, a partner in a firm of 6 partners, but as from the latter date he took over, as a "sole" practice, a practice until then worked by two partners. On what basis should he calculate his income for the year ending April, 1946?

⁂ (*a*) As regards the three months to June 30, 1945, his taxable income will be the amount of his share of the firm's assessment for 1945-6—e.g., 1/4 of 1/6 of the gross amount assessed. (*b*) As regards the nine months to April, 1946, the practice should be treated as a "new" one, and the gross income and expenses taken on the basis of the current year.

It may be convenient to take out a nine-months account to the end of March, but if preferred any other date can be taken—e.g., if a year's account to June 30, 1940, be the first account for the new practice, the income for the nine months to April, 1946, can be calculated at 3/4 of that for the full year. "X. A. X." cannot claim the cost of two new cars as a renewal of his present car; the second or additional car represents an investment of further capital in the practice. But of course the depreciation allowance can be claimed for both cars.

Appointment: Car Expenses

W. H. has been receiving an allowance of £60 a year for the use of his car. He contemplates selling his present car and buying a more modern one—at a cost of, say, £150 on the exchange. Can a deduction be claimed for such an expense?

⁂ Fundamentally the question is one of fact—i.e., Does the allowance of £60 a year cover the expense which W. H. "necessarily" incurs?—and in considering that question it is to be presumed that it would have to be looked at over a period of years. Assuming that replacement of the car has become *necessary*, W. H. would seem to have good ground for claiming that the facts have proved that the £60 was insufficient, and that some annual deduction should be made from his salary for income-tax purposes. But it may be urged on the other side that he should first approach the employing authority for a further allowance, or alternatively for a supporting statement that the £60 allowance is insufficient in view of present costs.

Cash Basis

A. B. has bought a share in a practice from an outgoing partner who did specialist work. The firm has been assessed on the cash basis, and A. B. is buying a share of the debts outstanding, excluding a sum of £1,000 due to the firm for the, now discontinued, specialist work. This involves A. B. in paying tax on his share of the £1,000, although, so far as he is personally concerned, such receipts will not represent income. Is there any way of avoiding the inequity?

⁂ If the new firm is to maintain the cash basis of calculating their income-tax liability *all* professional receipts must be brought into the computation. There seem to be only two alternatives open to A. B.: (*a*) to persuade his partners to drop the cash basis—thereby putting the £1,000 out of the picture—and adopt the earnings basis for this and future years, or (*b*) to represent to them that in effect he, A. B., is being called upon to pay tax on sums which are not *his* income in order to preserve for the firm as a whole the advantages of the cash basis, and that the other partners might share the burden to some extent. It is evident that A. B. is in an unfortunate position.

Domestic Help

K. C. inquires whether a deduction can be claimed for the cost of a nurse whose employment to look after a baby is necessitated by the fact that his wife is working as an anaesthetist.

⁂ No. The point was taken on appeal to the High Court some years ago and decided against the taxpayer.

Starting Practice: Expenses

W. D. started practice in July, 1944. Can he claim as expenses (*a*) cost of removal of furniture, etc., and (*b*) cost of a nurse-housekeeper necessitated by family illness and the circumstances of removal?

⁂ (*a*) No. Such expenses are incurred not in carrying on the practice but in order to be in a position to carry it on. (*b*) No. The expense is of a private nature.

Deduction for Ownership of Premises

J. R. owns his house, subject to a ground rent of £10 a year. What can he deduct for "rent" and repairs?

⁂ *Rent.*—J. R. can deduct a proportion of the "net annual value" as assessed under Schedule A for income-tax purposes, but not the amount of the ground rent; the proportion being the ratio of the professional to the private use of the property. *Repairs.*—If the total expenditure can be divided as between the professional and private portions of the house, that part applicable to the professional portion can be deducted. If the expenditure cannot be so divided, probably a division on the same basis as for "rent" will be accepted.

LETTERS, NOTES, ETC.

Conditions in Iraq

The Baghdad British Community Council (Post Office Box No. 2, Baghdad, Iraq) sends the following note: In the past men and women have come to posts in Iraq with little knowledge of conditions in the country. This has caused dissatisfaction, which the Baghdad British Community Council is anxious to minimize. The Council has therefore prepared *Notes for the Guidance of those considering Employment in Iraq*, which it hopes may prove of value and reach as many as possible of those concerned. In order that it may do so the Council would be grateful if associations, institutes, societies, and other bodies would inform their members of the existence of this pamphlet and of whence it may be obtained. The price is 150 fils or 3s.

The Future of Populations

Dr. B. DUNLOP (Binfield, Berks) writes: Why would it be disastrous (Aug. 25, p. 258) to have, through low fertility, deaths exceeding births until our numbers in Great Britain were reduced to about 40,000,000? I believe those to be right who agree with the late Prof. Wicksell, the Swedish economist, that there is not a country in Europe and Asia which would fail economically to benefit greatly by halving its population. What I consider dangerous is that married couples in our poorest sections still have an average of more than two children per family.

Drug Treatment of Cancer

Dr. G. R. USMAR (Boston, Lincs) writes: With reference to the most interesting answer under this heading (Aug. 25, p. 271) on Oct. 17, 1944, I saw a patient suffering from a large fungating cancer of the right breast; operative treatment and radium, etc., were refused. She was given stilboestrol 1 mg. t.d.s. Within one week bleeding ceased. The district nurse noted that skin was beginning to appear around the edges. By January the skin had been completely re-formed. The general health of the patient was greatly improved. This was probably due to the external appearance of the cancer, for she did not gain weight, though her appetite had vastly improved. In May, 1945, she began to deteriorate in health, and in June, 1945, she died of cachexia due to secondaries in both lungs and secondaries in thoracic vertebrae. However, this drug treatment was most beneficial from the patient's point of view, and she was most happy in her last year. Of course I made a point of informing the relatives of the ultimate outcome (for they were inclined to hail stilboestrol as a miracle).

Constriction Ring

Lieut.-Col. F. R. W. K. ALLEN writes from the Indian Military Hospital, Poona: It appears from a case reported in the *American Journal of Obstetrics and Gynecology*, November, 1943, that adrenaline may sometimes relax a constriction ring of the uterus. Deep chloroform or ether anaesthesia may have a similar effect, but the rural practitioner may only have chloroform at his disposal. Vinesthene is alleged to have much less relaxing power on the uterus than chloroform. The pharmacologists tell us that a combination of adrenaline by injection and choloroform by inhalation is liable to induce auricular fibrillation. A number of textbooks on obstetrics recommend both injections of adrenaline and deep chloroform anaesthesia in the treatment of constriction-ring dystocia where delivery has become imperative. Is there really danger in a combination of adrenaline injections and deep chloroform anaesthesia in such a case? Could amphetamine (methedrine) be substituted for adrenaline to safeguard the parturient from the danger of auricular fibrillation without a reduction in the relaxation of the constriction ring? I have only once felt a constriction ring, and that was of a mild degree. After a forceps delivery I was waiting for the birth of the placenta. There was no haemorrhage, but we wished to return the patient to her bed and have the delivery table ready for the next case. I tried gentle expression without avail, so I passed my hand into the uterus and found a constriction ring about half-way between the external "os" and the fundus. The placenta was lying free above the ring and there was no difficulty in drawing it out. The parturient was not injured by either of my operations.

Ptyalism in Pregnancy

Dr. W. H. NELSON (Perth, Western Australia) writes: In the *Journal* of April 14 (p. 543) there was a query about ptyalism in pregnancy. Many years ago I attended a pregnant woman suffering from vomiting of an intractable nature and profuse ptyalism, so much so that her face was swollen and the skin in the mouth region was raw with the irritation of the spittle. She had already lost three pregnancies on account of this condition. I tried a few standard remedies—mist. bis. co., chloretone in capsule, etc.—without success. Then I gave her 20 drops of 25% benzyl benzoate in 90% alcohol, taken in water every two hours for three doses, and then every four hours. The effect was miraculous, and when I saw the patient the next day I did not recognize her, as the face was quite normal, only showing the burnt areas at the corners of the mouth. The ptyalism vanished with the first dose, and the vomiting also ceased. She had to continue taking the drug three times a day throughout the carrying period, as the condition recurred as soon as she stopped it. In the end she had a normal son, and everyone was happy.

Nocturnal Cramp

Dr. SIMONDS GOODING (Grays) writes: With reference to your correspondent's inquiry (Aug. 18, p. 240) about the prevention of nocturnal cramp, it may be of interest to him to know that following an attack of acute gluteal fibrositis I personally suffered with very acute attacks of nocturnal cramp in the calf muscles of the right leg. To remain in bed during an attack was quite impossible owing to the severity of the pain. Various preparations of morphine and codeine, nembutal, allonal, amytal, antipyrine, etc., all proved quite ineffectual. On the advice of my colleague, Mr. L. Casin, F.R.C.S., I finally tried prostigmin, taking half a 15-mg. tablet each night on retiring to bed. I derived considerable relief from this drug, which, though probably not a cure, certainly relieved the symptoms and made the nights more bearable.

Venereology

Lieut.-Col. HENRY RICHARDS writes: In Army medical jargon a venereologist is an officer with a special knowledge of the diagnosis and treatment of venereal diseases. I have been hoping that some classical scholar would register an authoritative protest against the use of the word in this sense. The persistence of the term would be a regrettable addition to medical nomenclature. In the first place the word is a hybrid, derived from Latin and Greek. Secondly, the word cannot possibly have the meaning now fastened to it. Venereologist can only mean a person with a knowledge of venery. An expert practitioner of the arts of love is not necessarily a specialist in the care of venereal diseases.

An Unusual Cause of Intestinal Obstruction in a Newborn Baby

Dr. H. R. UNWIN (Yeovil) writes: The following unusual case occurred recently in my practice. A baby boy 4 days old had not passed any meconium since birth and was starting to vomit. An examination of the rectum by the little finger showed that it was normal as far as could be reached, and no meconium was found on the examining finger. Gastric peristalsis was visible after feeds, but it was only on the fourth day that vomiting became a feature of the case. A laparotomy was performed and the following state of affairs was found. Torsion of the caecal end of the ileum had taken place through three complete turns. This had been made possible by a deficiency in the mesentery. Aseptic gangrene of the terminal 12 inches of the ileum had resulted, with section of the ileum at the upper limit of the gangrene, the ends of the divided intestine being completely occluded. The ileum above the section was very distended for about 6 inches. The treatment adopted was resection of the gangrenous and distended ileum with an end-to-side ileo-caecostomy. The baby lived for two days after the operation and then died with symptoms of unrelieved obstruction. No post-mortem examination was performed. It is probable that a paralytic ileus developed.

Anatomical Nomenclature

Mr. A. HOLLMAN writes from University College Hospital: Surely it is time that surgeons in general, and the authors of surgical anatomy books in particular, made an attempt to use the B.R. nomenclature. At present the student learns his anatomy in terms of the B.R. and then, on entering hospital, he has the further burden of learning obsolete synonyms. If this state of affairs were rectified it would materially ease the student's task of learning what is, anyway, an uninspiring subject.

Sleep-walking

Dr. M. N. PAI writes: Some suggestions have appeared in the *Journal* on the treatment of sleep-walking. The causes of sleep-walking may be classified as follows: (1) Psychogenic or partial sleep due to (*a*) anxiety states, or (*b*) genuine dissociation—e.g., hysteria. When not sleep-walking a patient often talks or shouts in his sleep. Sometimes he may open the door and walk a long distance before waking up. (2) Post-epileptic: (*a*) following a nocturnal fit, or (*b*) as an epileptic equivalent (instead of a fit). Here the patient usually gets up from his bed and almost immediately returns to it, or gets into another one if one is available. He seldom walks more than a few yards. A positive E.E.G. may confirm the diagnosis, but a negative one does not exclude epilepsy. (3) Hystero-malingering. Here, apart from walking, the patient carries out very complicated actions requiring careful thought and previous planning. There is always an immediate gain. Careful observation at night, hypnosis, or narco-analysis may help in the diagnosis. (4) Post-infective following meningitis, encephalitis lethargica, and chronic cerebral abscess. Here the patient may wander aimlessly in an apparently confused state. Other signs and symptoms help in the diagnosis. Treatment: (1 *a*) relieve the anxiety or give large doses of sedative at night; (1 *b*) psychotherapy and suggestion—e.g., hypnosis. (2) Epanutin at bedtime. 3 and 4 are difficult to treat.

Hospitals Day, Oct. 2

The Secretary of the London Hospitals Street Collections Central Committee writes: May I call attention to the first street collection in aid of London's hospitals since the coming of peace? Hospitals Day will be on Tuesday, Oct. 2. Collectors are urgently needed, and volunteers should offer their services to their nearest voluntary hospital or to Lord Luke, Chairman, Hospitals Day, 36, Kingsway, W.C.2.

Corrections

In the question and answer headed "Profuse Periods in a Young Girl," published in the *Journal* of Sept. 15, p. 374, the dosage of thyroid was given in error as 1 gramme daily. This should have read 1 grain.

In the question and answer on "Oil-in-water and Water-in-oil Emulsions" (Sept. 15, p. 374), it was said "the bivalent alkaline earths and trivalent gases invariably give rise to water-in-oil emulsions." This should have read, "trivalent bases."

In a question and answer discussing the use of tryparsamide in G.P.I. (Sept. 15, p. 374) it was said that bismuth and arsenic may be given "concurrently or alternatively." This should have read "concurrently or alternately."

BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 29 1945

FURTHER REDUCTION IN HOSPITAL INFECTION OF WOUNDS

BY

VALENTINE LOGUE, F.R.C.S., M.R.C.P.

AND

WYLIE McKISSOCK, M.S., F.R.C.S.

(From an E.M.S. Neurosurgical Unit)

Assessments of incidence of hospital infection of wounds in the World War of 1914–18 were made by Fleming and Porteus (1919) and by Stokes and Tytler (1918–19). The investigations of the former workers showed that 15% of all admissions were already infected with *Streptococcus haemolyticus* and that after a further stay in hospital of a week or more the incidence rose to 90%. Stokes and Tytler (1918–19) showed a rise in incidence of infection with *Str. haemolyticus* from 18.2% in the first seven days to 42.1% at the end of two weeks. The table below gives the incidence of infection with other organisms over the same period.

Swab	No. of Wounds	Str. haem.	Staph. aureus	Coliforms	Diphtheroids
Initial swab ..	165	18·2%	14%	23%	7·2%
1 to 7 days ..	60	21·6%	15%	10%	3·3%
4 to 14 days ..	19	42·1%	36·8%	26·3%	

After Stokes and Tytler (1919).

At the beginning of the Second World War the rate of hospital infection was still unpleasantly high. In 1940 Miles and others described 74 cases in which the percentage rate of cross-infection (or hospital infection) reached 58 for a combination of *Str. haemolyticus, Staph. aureus,* Gram-negative bacilli, and diphtheroids:

	Str. haem.	Staph. aureus	Gram-neg. Bacilli	Diphtheroids
Group 1 20 cases ..	40%	45%	15%	10%
„ 2 30 „ ..	13·3%	6·5%	10%	10%
„ 3 24 „ ..	25%	8·5%	33·3%	33·3%

Of the 74 wounds, 43 acquired new infecting bacteria, giving a total hospital infection rate of 58%. (After Miles *et al.*, 1940.)

In 1940 McKissock, Wright, and Miles found a cross-infection rate with *Str. pyogenes* of 15.4% in a series of air-raid casualties under routine local and systemic treatment with drugs of the sulphonamide group.

It would thus appear that relatively little abatement of the risks of hospital infection had taken place between the two wars in spite of the increase in experience during the intervening period, when certain reports, notably by Cairns and Cowan, indicated some of the more striking points in theatre and ward infection, all of them examples of hospital infection. It was in the light of this accumulated knowledge of cross-infection that McKissock, Wright, and Miles made the experiment which they recorded in 1941. They devised a dressing technique to reduce some of the more obvious risks of hospital infection. No attempt was made to block *all* channels of infection, but a serious assault was made upon the many channels which were laid open during the course of the dressing of wounds as ordinarily carried out in the hospital ward. The result of the adoption of an improved dressing technique over a four-months period, contrasted with a previous four-months period, showed a reduction of cross-infection with *Str. pyogenes* from 15.4 to 1.1%.

The present paper records the prophylactic effect of the improved dressing technique, which, since our 1941 report, has been in continuous use over a period of three years. In the first four months of its trial *Str. pyogenes* was used as the sole indicator of hospital infection, but in view of the marked diminution of the streptococcal infection rate obtained in the original experiment the scope was subsequently widened to include all the potentially pathogenic aerobic bacteria commonly found in wounds.

Conditions of the Three-year Trial Period

The trial was made for 20 months in one hospital, after which the unit was transferred to another hospital, where the remaining 16-months trial was held. Neither building was in any way modern from the structural standpoint and no special facilities were available to render the conditions of the experiment unusually favourable. During the first 20 months the staff was composed mainly of voluntary aid detachments with a small number of civil nursing reserves, while in the second hospital the staff consisted mainly of nurses in general training. The theatre staff remained substantially unchanged throughout, and was composed almost entirely of voluntary aid detachments. One fully trained sister was in charge of the theatre and the 70 beds comprising the unit. Junior medical personnel changed at roughly yearly intervals.

No special precautions were taken to avoid airborne infection other than insistence upon the completion of bed-making and ward-cleaning at least half an hour before the performance of dressings and the closure of all doors and windows during dressings. The dressing technique demanded the employment of one doctor and three nurses at each dressing and followed exactly the routine laid down in the original paper, which was somewhat more elaborate than that recommended in the M.R.C. Memorandum on the subject.

Material

There were in the whole period 1,129 wounds at risk, of which 882 were clean surgical incisions and 247 traumatic wounds. Of the latter, 231 already contained pathogens at the time of admission, while in 16 cases cultures from the initial wound swab were sterile. It is probable that in the later months of the three-year trial period the risk of hospital infection was less grave than in the earlier period by reason of the smaller number of septic cases admitted to the wards. During this period, however, there were nearly always some infected wounds to swell the reservoir of infection permanently pro-

vided by the respiratory tracts of medical and nursing personnel, the patients, and their visitors.

Technique of Investigation

Bacteriological Method.—Wound swabs were taken from all surgically inflicted wounds wherever there was a moist surface, gaping of the wound, eversion of a skin edge, or obvious clinical infection. A swab was taken from traumatic wounds at the time of the first dressing after admission to our department and again at *every* subsequent dressing (on an average about thrice weekly) until healing was complete. The initial swabs were cultured aerobically and anaerobically, but if no anaerobes were obtained on this occasion further anaerobic cultures were omitted.

Chemotherapy.—All patients with traumatic wounds were given a five-day prophylactic course of sulphapyridine, sulphathiazole, or sulphamezathine, amounting to 30 g. in all. Open traumatic wounds were dusted with sulphanilamide powder, and a small number of the clean surgically inflicted wounds were similarly dusted in layers as they were closed. Penicillin was not given to any patient in the series.

"Hospital" or Cross Infection.—Infection has been classed as "silent" or "clinical," according to the following criteria: *Silent infection* was indicated by the growth of organisms from a bacteriological swab taken from a healed or healing wound where no evidence of clinical infection could be found; *clinical infection* was considered present if there were local signs such as stitch abscess, purulent discharge, swelling and oedema, etc., or where there was general constitutional disturbance. An attempt has also been made to separate true theatre infection from ward infection, as will be seen in Table II. Theatre infection was presumed: (1) where organisms or evidence of infection was found beneath the silver-foil seal applied at the end of the operation; (2) where infection occurred within the first four days after operation; (3) where infection started in the deep layers of the wound, the superficial layers being healed.

Results in Surgically Inflicted Wounds

There were 18 cases of infection (silent and clinical) in the 882 wounds—an incidence of 2.4%.

TABLE II

Case	Where Infected	Day of Infection	Organism Infecting	Comments	Type of Infection
1	Ward	3rd	Staph. aur.	Bandage removed by patient	C.I.
2	"	10th	Staph. alb.	Constantly scratching wound	C.I.
3	"	34th	Staph. aur.	Incision penetrated by comb tooth	C.I.
4	Theatre	4th	Staph. aur.; Str. faecalis	Bone flap removed	C.I.
5	"	7th 1st dressing	Staph. alb.	Healed in 36 days	C.I.
6	"	4th 1st dressing	"	" 6 "	S.I.
7	"	4th 1st dressing	"	" 7 "	S.I.
8	"	7th 1st dressing	Not swabbed	" 18 "	C.I.
9	"	7th 1st dressing	"	" 16 "	C.I.
10	"	2nd	Staph. alb.; Bact. coli	" 11 "	C.I.
11	Ward	9th	Staph. alb.; diphtheroid	" 10 "	S.I.
12	"	10th	Staph. aur.; non-haem. strep.	" 75 "	C.I.
13	"	7th	Staph. aur.	" 100 "	C.I.
14	"	10th	Staph. alb.; diphtheroid	Not healed on discharge; C.S.F. leak	S.I.
15	"	8th	Staph. aur.; diphtheroid	Healed in 3 days; C.S.F. leak	S.I.
16	"	5th	Staph. alb.	Healed in 37 days	C.I.
17	"	10th	"	" 26 "	C.I.
18	"	7th	"	" 5 "	S.I.

Staph. aureus refers to coagulase-positive staphylococci, and *Staph. albus* to coagulase-negative staphylococci. C.I. indicates "clinical infection." S.I. indicates "silent infection."

Analysis of these 18 cases of added infection revealed that the patients themselves were responsible on three occasions. Two patients removed their bandages and scratched their own wounds, and one penetrated her healed incision with a comb on the 34th day after operation. Thus 15 cases only, of which 7 occurred in the theatre and 8 in the ward, may be considered as true examples of hospital infection of wounds—an incidence of 1.7%. The theatre infection rate is 0.8% and the ward cross-infection rate 0.9%.

None of the 18 cases cross-infected contained *Str. pyogenes*, and of the 8 cases infected in the ward 3 were silent infections and only 5 showed clinical evidence of sepsis. The high incidence of *Staph. albus* (5 out of 8 cases) was presumably due to the prevalence of this organism on the human scalp and hair.

Results in Traumatic Wounds

In the series of 247 traumatic wounds—most of which were due to enemy action and were of the heavily contaminated variety familiar to those who have had the care of air-raid casualties—231 were already infected on admission. *Str. pyogenes* was present on admission in 11.3% (28) of the infected wounds. A total of 27 of the 247 wounds later yielded additional organisms (of some type) as a result of hospital infection—an incidence of cross-infection of 10.9%. Of the 27 cases only 4 became cross-infected with *Str. pyogenes*—an incidence of 1.6%.

Comparing the figures with those of Stokes and Tytler, it can be seen that the increase in incidence of *Str. haemolyticus* in wounds from 18.2% to 42.1% in their series has not been in any way approached in ours. The rise, in our series, of infection with *Str. pyogenes* is only from 28 patients (whose wounds contained *Str. pyogenes* on admission) to 32 during the whole period of stay in hospital—i.e., a percentage rise from 11.3 to 12.5.

We can thus show complete protection from *Str. pyogenes* in 882 clean surgical wounds. In traumatic wounds the incidence was reduced from 1.6% from our own "pre-dressing technique" incidence of 15.4%. The total incidence of cross-infection of 11.3% shows a considerable reduction when compared with the figure of Miles *et al.* of 58% obtained in the early stage of the war.

Conclusions

A strikingly low rate of cross-infection of wounds has been maintained during the use of the improved dressing technique in our department over a three-year period. As no material alterations in the conditions of the experiment have taken place during the three years it is fair to assume that the improved dressing technique is alone responsible for the lowering of the rate of cross-infection. The continuation of the technique over so long a period of time, under the conditions of war, with all its shortages of material and man-power, proves that there is no essential difficulty in observing the rules laid down by us in our original paper.

As to the intensely practical value of this reduction of hospital infection one has but to consider the saving in hospital-bed days. A wound which breaks down as a result of added infection may easily lead not only to days but to many weeks or months of additional stay in hospital, with all its cost in food, bedding, drugs, dressings, and the time of nurses and doctors, apart from the unfortunate and sometimes lethal effect upon the patient.

Summary

An improved dressing technique designed to avoid cross-infection has been in use for a period of three years, during which time 1,129 wounds have been treated.

882 wounds were surgically inflicted, while 247 were traumatic and mainly the result of enemy action.

The total incidence of cross-infection in the 882 clean cases was 2.4% and in the 247 traumatic wounds 10.9%.

Str. pyogenes has been eliminated as a cross-infecting agent in the 882 clean surgical wounds and its incidence in traumatic wounds reduced to 1.6%.

The improved dressing technique is considered to be the sole factor in these striking reductions upon previously published figures for hospital (or cross-) infection of wounds.

A SYNDROME RESEMBLING ADDISON'S DISEASE, WITH SEVERE ANAEMIA, STEATORRHOEA, AND MELANURIA

BY

S. LOCKET, M.R.C.P.

Assistant Physician, County Hospital, Pembury, Kent

A case resembling Addison's disease with a severe normocytic normochromic anaemia, which was at first treated as a macrocytic anaemia of unknown aetiology, is here described. Addison (1855) in his original description of the disease mentioned anaemia, but it is not accepted nowadays as a common or characteristic feature of the syndrome (Goldzieher, 1939).

Case Record

Miss A., aged 22, had a sudden attack of stomatitis in Feb., 1943. At times it was so severe that for several days she was unable to eat or drink. It continued until her admission to a military hospital on July 5, 1943. She had post-prandial upper abdominal pain and loose motions. Amenorrhoea had been present for three months. She was extremely ill, had a lemon-yellow tint, and was wasted. Shallow ulcers were present inside the mouth. The spleen was not palpable and there were no changes in the nails. Blood picture on admission: haemoglobin, 36%; R.B.C., 1,600,000; colour index, 1.1; W.B.C., 2,000, with a normal differential white count; reticulocytes 0.1%; polychromasia; occasional Howell-Jolly bodies; marked anisocytosis; one primitive megaloblast, and one normoblast. Red-cell fragility was normal.

She was treated with liver extract intramuscularly, iron, marmite, vitamin C, vitamins A and D, nicotinic acid, and a high-calorie diet. The stomatitis recurred several times. She apparently improved, and on discharge the blood picture was: haemoglobin, 92%; R.B.C., 4½ millions; W.B.C., 9,000. A test meal showed that free acid was present. She was still feeling subnormal, however, and the amenorrhoea persisted. She was discharged from the Forces in 1943, all treatment being discontinued.

Two weeks before admission to the County Hospital, Pembury, on March 8, 1944, she had an attack of "influenza." A blood count showed R.B.C. 2,000,000. Liver injections were given without response. The temperature persisted.

On admission she complained of lack of energy, dizziness, especially on standing, cold hands and feet, and sore mouth. There were no previous illnesses. Her mother, two stepbrothers, and two stepsisters were alive and well. Her father died from an unknown cause.

Examination.—The temperature was 99.5°. She was a thin short girl, and lay in bed, making few spontaneous movements. She had a pale waxy appearance and there were numerous dark-brown pigmented spots on the limbs, trunk, and face, none exceeding 3 mm. in diameter. She stated that these spots first appeared when she became sick in Feb., 1943. They began to disappear when her condition improved in the military hospital, but have recently been increasing. The apex of the heart was 3½ in. from the midline in the fourth left intercostal space; there was an apical systolic murmur. The blood pressure was 86/34 mm. Hg. Lungs, normal. The tongue was clean and not abnormally smooth. There were a few shallow ulcers on the inner side of the lip, 3–4 mm. in diameter. They had a greyish base and red periphery, and in appearance were identical with those of aphthous stomatitis. Numerous pigmented spots were present on the hard palate. The liver and spleen were not palpable. C.N.S., normal. Urine: Albumin, *nil;* sugar (Benedict), *nil;* reaction, acid; specific gravity range, 1010–1030; volume, maximal 25 oz. daily, minimum 6 oz. daily; average daily volume of urine, 20 oz., dark orange-yellow with a tinge of brown; no blood and no casts. Blood examination showed: haemoglobin, 34%; R.B.C., 1.55 millions; colour index, 1.1; reticulocytes, 1%; mean cell diameter, 7.7 μ; W.B.C., 9,400—polymorphs 70%, lymphocytes 18%, large hyalines 4%, eosinophils 8%; anisocytosis and polychromasia present.

In view of the original diagnosis the patient was given 2 c.cm. of neohepatex daily for six days, and two pints of blood were transfused. No improvement followed. The blood pressure did not rise, there was marked asthenia, and the reticulocyte count remained at 1%. From the seventh day (March 15) 5 c.cm. of extract of suprarenal cortex (*B.P.C.*) was given intramuscularly daily for six days, and then desoxycortone acetate 10 mg. daily for eight days—i.e., until March 29. The blood pressure rose rapidly (March 23). The reticulocyte count began to rise between March 18 and 28. It was found that 15 mg. of desoxycortone acetate every other day maintained the blood pressure at 120/80 mm. Hg. The haemoglobin increased; and on discharge it was 80–85% (Haldane scale); R.B.C., 4 millions, and colour index 1.0 (Fig. 1).

The evening pyrexia fell to normal 11 days after there was clinical response to desoxycortone acetate, suggesting that the pyrexia was also due to the cortical insufficiency. This is at variance with the usually described "subnormal temperature" (Leyton, 1939), though Loeb (1940) describes pyrexia occurring pre-terminally in this disease.

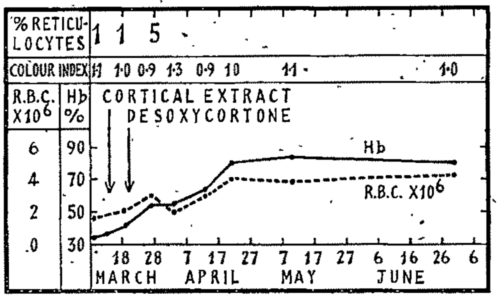

FIG. 1.—Showing haemoglobin and erythrocyte response to treatment.

On admission the sodium ion content of the blood was at a normal minimum, while the blood potassium ionic content was at a normal maximum. It is interesting to note in Fig. 2 the rise in the potassium ion as the sodium ion falls, and vice versa. Radiographs of the chest were normal. A test meal showed that free acid was present, and a barium meal and follow-through revealed nothing abnormal.

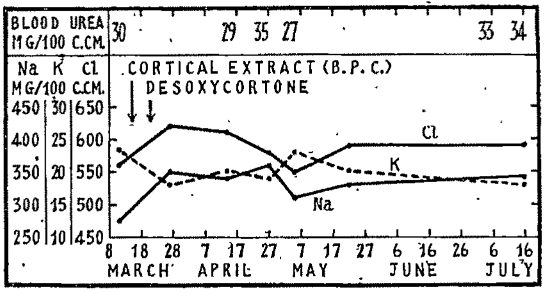

FIG. 2.—Showing blood ionic changes during treatment.

The patient rapidly became ambulatory; her appetite was ravenous and, except for occasional headaches, she appeared to be a normal active girl. Towards the end of April the blood pressure fell steadily from 120/75 to 105/60 (Fig. 3) and general asthenia returned; desoxycortone acetate and sodium chloride were pushed (NaCl 15 g. and desoxycortone acetate 30 mg. daily). She became drowsy in the second week in May, when the blood pressure rose to 140/90 mm. Hg and some oedema of the legs appeared (Loeb, 1940). Cutting down the salt intake to 4 g. daily and the desoxycortone acetate to 15 mg. every other day resulted in a marked improvement, with a fall in blood pressure. Although she would not drink much and the urinary output was not high (20 oz. daily) before treatment, the blood urea was never above 35 mg. per 100 c.cm.

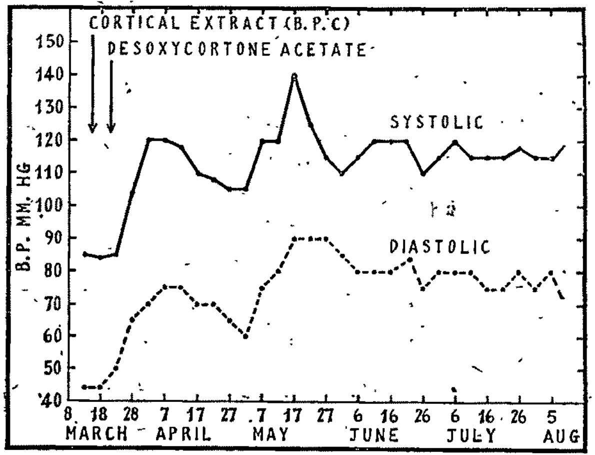

FIG. 3.—Record of blood pressure during treatment.

Subsequent Progress

On Oct. 26, 1944, 500 mg. of desoxycortone acetate was implanted subcutaneously under local analgesia at the West Glamorgan County Hospital, Neath. On Nov. 10 the blood pressure rose to 152/100 and there was some puffiness of the face. Her blood pressure thereafter remained at a satisfactory level until Jan. 8, 1945. A further subcutaneous implantation of 600 mg. of desoxycortone acetate was made on Jan. 17. The blood picture on Dec. 11, 1944, was: haemoglobin, 86%; red cell count, 4½ millions; reticulocytes, 0.11%.

She was readmitted to this hospital on Feb. 8, 1945. The blood picture was then: haemoglobin, 77% (Haldane scale); red cells, 3.53 millions; colour index, 1.1; white blood count, 7,400—polymorphs 67%; mean cell diameter, 7.4 μ; reticulocytes 3%. A test meal showed low free acid. Blood pressure range, 110–115/60–70. Blood ions: Na, 335 mg.; K, 22.5 mg.; chloride, 635 mg. (as NaCl); blood urea, 30 mg. per 100 c.cm. The urine contained melanin. Faeces: Neutral unsplit fat, 7.5%; free fatty acids, 13.1%; soaps, 39.3% (total fat, 59.9%). Of the faecal fat 12.5% was unsplit and 87.5% was split.

It was noticed during this admission that the incision where the crystals had been implanted was discharging a little pus. On various days during the follow-up period she discharged crystals of desoxycortone acetate equal to 300 mg. Investigations were carried out during this stage of her illness, without any further injections of desoxycortone acetate. On May 3 her blood pressure had fallen to 90/60. On May 14 asthenia was marked; B.P. 100/60. Two days later she complained of nausea, and then vomiting and diarrhoea began (May 19), and became quite persistent. Vertigo was marked. Injections of desoxycortone, 15 mg. every other day, were restarted on May 23, with rapid cessation of the gastro-intestinal symptoms. On May 25 300 mg. of desoxycortone acetate was implanted subcutaneously. On June 4 her blood pressure had risen to 120/90 and she was able to walk about the ward, feeling much improved.

Differential Diagnosis

That this patient is not suffering from *pernicious anaemia* is indicated by the presence of free acid in the test meal, the colour index range of 1.0 to 1.1, the mean cell diameter (halo method) in neighbourhood of 7.5 μ, the absence of response to liver, and the dramatic response to desoxycortone acetate. Against a diagnosis of *Simmonds's disease* is the absence of a history of past pregnancy and post-partum haemorrhage, no bradycardia, no loss of secondary sexual characteristics, and the presence of pigmentation. *Pellagra* would presumably respond to liver injections, owing to the high nicotinic acid content of the usual liver extracts. The absence of reducing substance in the urine and the normal colour of the cartilages of the nose and ears are against diagnoses of *ochronosis* and *alkaptonuria*. No evidence of a primary *melanotic carcinoma* was found. The choroid appeared normal; no glandular or hepatic enlargement was present; and there was a dramatic response to desoxycortone.

Mesenteric chyladenectasis and *steatorrhoea*, with features of Addison's disease, have been described (Glynn and Rosenheim, 1938). The patient improved for a while on extract of suprarenal cortex (*B.P.C.*), but ultimately relapsed and died. At necropsy no lesion of the suprarenals was found, and a functional deficiency of these glands was postulated. Suprarenal insufficiency was diagnosed in a case of non-tropical sprue by Holmes and Starr (1929), but the rapid improvement in their patient with daily parathyroid extract Collip made this diagnosis, in their opinion, untenable. Functional suprarenal insufficiency has also been suggested by Gloor (1929–30) in non-tropical sprue.

Tuberculosis of the Suprarenals and the Mesenteric Lymph Glands.—The rapid response to desoxycortone acetate indicates that the steatorrhoea is due to a functional failure of absorption and not to an organic obstruction.

Idiopathic Steatorrhoea.—Many cases of idiopathic steatorrhoea have been seen in this hospital in the last few years, and a further paper on these cases is in preparation. They differ from the present case in many features. They give histories of much longer duration, the weight loss is more pronounced, and anaemia varies from hypochromic microcytic to hyperchromic macrocytic. Stools are pale and greasy, and have a persistently high total fat and split-fat content. The tongue is smooth and may show aphthous ulceration. The blood pressure is variable, depending upon the age of the patient, but the systolic was not below 100 mm. Hg except terminally or when the patient was collapsed, and then there was no response to desoxycortone acetate. A high-potassium low-sodium diet with added potassium chloride did not produce an exacerbation of the condition or a fall in blood pressure. The blood calcium is usually low in idiopathic steatorrhoea and tetany is frequent, but there may be a hypercalcaemia in Addison's disease (Loeb, 1940). In the case under discussion the blood calcium was 10.6 mg. per 100 c.cm. Pigmentation of skin was variable, but was not present on mucosae. Test meals usually showed an achlorhydria. Oedema of the limbs, in many cases massive, was often present on admission before the onset of any treatment.

Discussion

Addison's disease is suggested by the history, pigmentation of skin and mucosae, ionic changes in the blood, low blood pressure, melanuria, and response to desoxycortone acetate—and also the fall in blood pressure and onset of vomiting, diarrhoea, and vertigo, on deliberately withholding the desoxycortone acetate (see progress notes). The marked improvement with desoxycortone acetate suggests that the entire clinical picture is a single entity.

In Addison's disease the sodium loss leads to dehydration, haemoconcentration, diminished glomerular filtration, and an increase in the blood urea. Increased protein destruction occurs in dehydration (Black, 1942), and this contributes to the raised blood urea. The normal blood urea figures in this patient suggest adequate glomerular filtration and a normal blood volume.

It was noticed that the urine was dark in colour, particularly after it had been standing for 24 hours. When at the end of April the blood pressure fell the urine became black with pigment identified as melanin. The urine eventually became paler, though its colour fluctuated considerably. The increased alkalinity of the urine on standing had resulted in the rapid oxidation of melanogen to melanin. At this time, too, it was noticed that the stools had a very foul odour, were of enormous volume, and looked like the stools of idiopathic steatorrhoea, being unformed and very greasy. In the cold they set like cooling fat; they were, however, dark and not clay-coloured. When the blood pressure rose the stools diminished in size and became almost normal in appearance, though now and again, with a bout of "general malaise" but no obvious fall in the blood pressure, blood sodium, or blood chloride ions, they would revert to a "steatorrhoeic" state. In three fat estimations of these stools—the third during a remission—the total fat was 48%, 73%, and 21% respectively, and in every instance over 75% was split fat.

Fat Analysis : % of Dried Faeces

			During Remission produced by Desoxycortone Acetate
Neutral unsplit fat	6·4%	16·6%	1·6%*
Free fatty acids	32·1%	24·4%	14·2%
Soaps	9·1%	32·2%	5·0%
Total fat	47·6%	73·2%	20·8%
% of faecal fat: (a) Unsplit	13·4%	22·7%	7·7%
„ „ (b) Split	86·6%	77·3%	92·3%

Steatorrhoea, with or without diarrhoea, has been demonstrated in Addison's disease (Zondek, 1944) and also in experimental adrenal insufficiency (Verzar and McDougall, 1936). It is suggested that the dark colour of the stools might in this patient be due to melanin.

Abnormality of cell permeability would account for the failure in fat absorption, the split fat indicating that the enzymes of the bowel were functioning normally. In adrenalectomized animals there is a marked delay in the rate of absorption of sodium, potassium, and chloride ions from the ileum (Hadfield and Garrod, 1942), and the production of a stool comparable to that in chronic jejuno-ileal insufficiency would be understandable. Actual atrophy of the alimentary canal comparable to that observed in idiopathic steatorrhoea appears to be uncommon in Addison's disease (Guttman, 1930).

A glucose-tolerance test showed a low curve but a normal fasting sugar. An intravenous glucose-tolerance test to find whether this apparent increased glucose tolerance was really due to poor intestinal absorption was not done. However, it is known that in Addison's disease there is a greatly increased glucose tolerance due to unbalanced action of insulin, and that this state of hypoglycaemia is not corrected by injections of desoxycortone acetate.

It is stated by some authorities that "anaemia may occur in Addison's disease but is not specific" (Whitby and Britton, 1942). According to Goldzieher (1939), "anaemia, originally mentioned as a feature by Addison, is actually not a symptom of the disease. The red cell count is not infrequently increased, and the haemoglobin higher, as the result of the inspissation of the blood." Other sources (Leyton and Simpson, 1936–41) tentatively suggest that the adrenal cortical hormones might be needed for adequate haemopoiesis, but still favour failure of iron absorption, possibly due to achlorhydria, as the more likely cause.

Brown and Roth (1925) found definite anaemia in one of 17 cases of Addison's disease they observed. It showed haemoglobin 50% and 53% (Dare scale) and R.B.C. 2,960,000 and 3,280,000. The patient died three days after admission. They quote a case observed by Neumann with a red cell count of 1,120,000. The lowest figures given by Goldzieher (1939) are Hb 67%, R.B.C. 3,450,000; and by Rowntree and Snell (1931) Hb 30% and 39% (Dare scale), R.B.C. 1.5 and 1.9 millions.

The rapid response to desoxycortone acetate in the present case suggests that this substance is here essential for the normal formation of red cells. That intestinal insufficiency, as indicated by the high fat content of the stools, was not the cause of the anaemia is shown by the persistent colour index of 1.0 to 1.1 (excepting one reading of 1.3); this argues against the absence of the pernicious anaemia haemopoietic factor being the primary cause, as also does the absence of therapeutic response to liver. The normal colour index suggests that the absence of iron is not the primary cause. As there was no achlorhydria, this too could not have participated in the causation of the anaemia. Indirect evidence of the specific action of the cortical hormones in haemopoiesis is that polycythaemia occurs in suprarenal cortical excess, due to cortical hyperplasia, adenoma, or carcinoma.

It is probable, therefore, that in this case of Addison's disease the anaemia is due to the direct specific effect on the bone marrow of an absence of suprarenal cortical hormone. This may often occur in Addison's disease, but, being slight, may be hidden. In addition, diminished bowel absorption may add the features of iron-, or "liver-," deficiency anaemia. To these factors must be added the effect of dehydration (probably absent in this case), acidosis, and ionic change on the individual and total red cell volume. A variable blood picture may thus result. A normocytic anaemia of this degree of severity will, in view of the failure of response to all the usual haematinics, resemble "idiopathic aplastic anaemia."

The presence of "one primitive megaloblast" in the earliest blood count does not make the diagnosis a macrocytic anaemia, as none have been seen since then. The 8% eosinophils on first admission to this hospital may have been due to the injections of liver before admission, though eosinophilia has been reported in Addison's disease by Zondek (1944).

Melanuria is rare in Addison's disease, and it is not more common or more pronounced in cases of the disease with deeper pigmentation. It is said to occur in severe cases (Karsner, 1938). This suggests that cell permeability is not dependent upon the same cortical hormone the absence of which results in pigmentation. A severe alteration in cellular permeability may therefore occur with slight or no pigmentation, and vice versa. Non-pigmented cases of Addison's disease have been described by Conybeare and Millis (1924) and White and James (1927). A severe alteration in cellular permeability might result in the liberation of melanin, and its immediate precursor melanogen, into the circulation; the melanin is then reduced to melanogen in the serum (Karsner, 1938), and excreted in the urine, where it is reoxidized to melanin.

In the present instance there was no direct relation between exacerbation of the syndrome and of the stomatitis, which, however, improved when the clinical condition responded to desoxycortone acetate.

Methods Used

Faecal Fats.—The Soxhlet extraction method, substantially the same as that of Holt, Courtney, and Fales, and referred to in Harrison's *Chemical Methods in Clinical Medicine*, 2nd edition, pp. 469 and 470.

Blood Chlorides.—Whitehorn's method (*J. biol. Chem.*, 1920–1, **45**, 449).

Serum Sodium.—Modification of method of McCance and Shipp described in Harrison's *Chemical Methods in Clinical Medicine*, pp. 379 and 380.

Serum Potassium.—Method described by Jacobs and Hoffman (*J. biol. Chem.*, 1931, **93**, 685).

The serum sodium and serum potassium methods are colorimetric methods, and a "Spekker" absorptiometer has been used in these estimations.

Summary

A case simulating Addison's disease with severe normocytic normochromic anaemia, steatorrhoea, and melanuria, and its treatment, are described.

A tentative explanation of the underlying mechanism of the syndrome anaemia, steatorrhoea, and melanuria is put forward.

The differential diagnosis is discussed.

The relevant literature is reviewed.

I wish to thank Dr. Osman for his kind help and advice in treating this case and writing this paper; Dr. Jones, of the County Laboratory, Maidstone, and Dr. Taylor and Mr. Rogers, of the Pathological Department, County Hospital, Pembury, for the haematological and biochemical investigations. Also Dr. Grasby, medical superintendent, and Dr. Ponder, County Medical Officer, for permission to publish this report; the military authorities for sending data obtained in a military hospital; and the medical superintendent of the West Glamorgan County Hospital, Neath.

THREE CASES OF CLOSED INTRA-ABDOMINAL INJURY

BY

H. N. G. HUDSON, M.B., F.R.C.S.

Squadron Leader, R.A.F.V.R.; Surgical Specialist to an R.A.F. Mobile Field Hospital

Cases of visceral injury resulting from blunt injuries to the abdomen are interesting clinically. The exact mechanisms by which the lesions are produced have occasioned some discussion. The following are case notes of three such injuries produced by three different types of trauma. All three cases were seen within the latter six months of 1944.

Case I: Propeller Accident; Ruptured Jejunum

The patient—a young man of the Fleet Air Arm—gave a history of having been struck in the abdomen by the blades of a propeller, against which he was leaning when the engine of the aircraft was started. The only visible external injuries were abrasions in the right groin and over the lower half of the sternum. At first he appeared to have no serious internal injuries, and his general condition was good. He was admitted to R.A.F. sick quarters, where the medical officer wisely put him to bed and made half-hourly records of his pulse rate and blood-pressure readings. His pulse rate continued to be normal and constant, but he vomited twice. In view of his abdominal symptoms, the M.O. was not happy about him.

When I first saw the patient there were guarding and tenderness of the upper abdomen, but peristalsis was audible through the stethoscope. In view of this observation, his general condition, the pulse rate, and blood-pressure readings, it was thought at first that his pain and guarding were probably not due to a ruptured jejunum. However, a "straight" radiograph of his abdomen (taken with a portable machine while the patient was sitting erect) showed free gas under both cupolas of the diaphragm, and clinched the diagnosis. Conditions prevailing at the time prevented his admission to our mobile hospital, and he was transferred to the Royal Victoria and West Hants Hospital.

Laparotomy, performed by Mr. Markaby, showed a laceration about the size of a threepenny-bit in the jejunum, 10 in. from the duodeno-jejunal flexure. Prolapsed mucosa had effectively plugged the laceration. There was a small quantity of free fluid in the peritoneal cavity, and some local peritonitic reaction, with flakes of lymph round the site of laceration. The small gut was dilated proximally. Distally it was empty. The laceration was closed with a purse-string suture, reinforced with a row of Lembert sutures.

Mr. Markaby, in a letter, says that recovery was uneventful, and that the patient was discharged from hospital three weeks later. Up to the time of operation (16 hours after the accident) the pulse rate had been constant and the blood pressure had remained at 135/75 mm. Hg.

Case II: Crush Injury; Ruptured Stomach

This patient was crushed between two heavy lorries, the bumper of the moving vehicle striking him in the epigastrium. His abdomen was compressed with considerable force in an antero-posterior direction. Severe abdominal pain and distress immediately followed the injury. He was admitted to our hospital two hours after the accident.

On examination he was evidently in great pain. His whole abdomen was rigid. Resuscitative measures were begun forthwith, and these were continued during the operation. The abdomen was opened through a generous left upper paramedian incision. The left upper rectus abdominis was found to be partially ruptured. The peritoneal cavity contained blood and food debris in quantity. The stomach was ruptured 3 in. from the pylorus. The rent was about 7 in. long and ran at right-angles to the long axis of the viscus, extending from the anterior surface across the greater curvature on to the posterior surface. The transverse mesocolon was split in a vertical direction from its colonic attachment to near its root. The lesser sac was thus freely opened and contained blood and food debris. The colon was not injured and its blood supply not impaired. There was an extensive retroperitoneal haematoma in the region of the pancreas.

No other injuries were found. The rents in the stomach and mesocolon were repaired. As much as possible of the blood and food debris was removed from the peritoneal cavity. The retroperitoneal haematoma was left untouched, and the abdomen was closed without drainage. Gastric suction through a nasal tube was begun immediately. The intravenous drip was kept going with glucose-saline. Penicillin, sulphathiazole, and anti-gas-gangrene therapy was started as a prophylactic measure against infection of the retroperitoneal tissues.

The patient's condition next morning was satisfactory. He said that he was in no pain but felt thirsty. He had passed urine. Twenty-four hours after the operation, however, signs of cardio-respiratory failure set in relatively suddenly, and he died four hours from the onset of symptoms. During these four hours his colour remained fairly good and his extremities were not cold. His pulse was rapid and weak. His respiration became rapid and gasping, but there was no "bubbling" in the lungs and he did not complain of pain in the chest.

Post-mortem Examination.—There was a quantity of blood-stained fluid in the peritoneal cavity. The suture lines were sound. There was an extensive retroperitoneal haematoma extending from the region of the pancreas along the line of the great vessels to the pelvic brim. The quantity of blood lost into the haematoma was not sufficient to account for death. There was considerable haemorrhage around and a little haemorrhage into the pancreas. No areas of fat necrosis were observed. The kidneys were very congested, but were unruptured. There were no injuries to the spleen, liver, or intestines. The suprarenals showed no gross abnormality. There was a tear in the internal coats of the abdominal aorta, but this had not been the source of the haematoma. The heart appeared normal. Only post-mortem clot was found in the main branches of the pulmonary artery. The lungs showed no gross abnormality. The diaphragm was not ruptured.

Case III: Kick on Left Lower Ribs; Ruptured Spleen

An airman aged 23 was kicked in the left lower ribs while playing football. He was "winded," but after a few minutes continued with the game. Later he returned to his unit by motor coach. He noticed nothing much amiss, and after a good night's sleep arose as usual next morning. At 11 a.m.—he had been injured at 4.30 p.m. the previous day—he was straining at stool, when he was seized with acute pain in the left hypochondrium. He also noticed pain in his left shoulder. He was emphatic that these pains had not previously been experienced. His unit medical officer observed him for a short time and sent him in as a case of ? ruptured spleen.

On admission his pulse rate was 80 a minute and blood pressure 120/70. His haemoglobin was 90%. He was sweating and in pain. On examination he was tender over the whole abdomen, but especially so in the left hypochondrium and left loin. There was no rigidity. The area of splenic dullness was increased and there was shifting dullness. When the patient was turned on one side he complained of abdominal pain on that side. He was tender in the pelvic pouch. The urine was normal. Blood transfusion was started, and was continued during the operation. The abdomen was opened through an adequate upper left paramedian incision. The peritoneal cavity contained a quantity of free blood. The spleen was surrounded by a mass of blood clot and presented two large lacerations on its convex surface and on its upper and anterior border. Splenectomy was performed, and after removing the clot and free blood so far as was possible the abdomen was closed without drainage. The temperature did not settle for 10 days, but the patient felt and looked fit. Fourteen days after his operation the white cells numbered 21,000 per c.mm. (neutrophils 71%, lymphocytes 23%, monocytes 3%, eosinophils 1%, basophils 2%). He was evacuated to England, and I have no further information regarding him. The patient had been stationed in the Middle East for two years, but had never had malaria or any other illness. Histological examination of the spleen showed no pathology apart from the lacerations.

Discussion

In Case I the jejunum was ruptured as the result of a sharp glancing blow on the relaxed abdomen. The lesion produced was a small partial tear 10 in. from the duodeno-jejunal flexure. The appearance of the bowel and the near-by tissues was not such as to suggest that the bowel had been crushed against the spine by the blade of the propeller (personal observation). If this had been the mechanism responsible then one would have expected to find considerable bruising of all the tissues so forcibly compressed, and not only an isolated tear of the small gut.

The site of jejunal tears in cases of "subcutaneous" injuries is reported to be fairly constant ("near the fixed portions of the gut"). If the rupture is due to a localized crushing of the bowel, then it must follow that only those injuries in which the force is applied to these sites produce rupture, and in cases of blows elsewhere on the abdomen rupture does not occur. Can this view be accepted? (At present I have not access to the relevant literature.)

In Case II the force was of a powerful crushing nature, relatively slowly applied. Here it was the thick-walled full stomach which was ruptured, and there was extensive bruising of the tissues on the posterior abdominal wall, but no rupture of the other viscera and, in spite of the great compression of the abdomen, no rupture of the diaphragm.

In Case III the force was a sudden kick on the elastic ribs overlying the spleen. The ribs were not fractured, but they transmitted the sudden force to the organ, which was ruptured in two places. The mechanism here would seem to be the creation of a pressure wave in the semi-fluid pulp of the spleen and its contained blood, sufficient to burst open the capsule of the viscus. The length of the interval between the injury and the first onset of symptoms was striking.

In Case I the absence of any marked constitutional symptoms even 16 hours after the bowel had been ruptured was interesting.

For permission to publish these case notes I am indebted to Air Marshal Sir Harold Whittingham, Director-General Medical Services, Royal Air Force, and to Wing Commander H. F. Harvey, Officer Commanding our Mobile Field Hospital.

I wish to thank Air Vice-Marshal Stanford Cade, Consultant in Surgery to the Royal Air Force, for much help and encouragement.

W. M. Johnson and O. T. Davis (*South. med. J.*, 1945, **38**, 373) who record their observations on 22 cases of acute pancreatitis come to the following conclusions: (1) Pancreatitis is far commoner than is generally thought. (2) Pancreatitis can often be suspected clinically, and can be diagnosed almost invariably by the serum amylase test properly performed. (3) The aetiology of pancreatitis is still questionable; it may be due to a number of factors. (4) The fact that pancreatitis is far more often a medical than a surgical condition makes its recognition exceedingly important.

THE RISKS OF GASTROSCOPY WITH THE FLEXIBLE GASTROSCOPE

BY

C. M. FLETCHER, M.D., M.R.C.P.
First Assistant, British Postgraduate Medical School

AND

F. AVERY JONES, M.D., M.R.C.P.
Senior Physician, Central Middlesex County Hospital

When Wolf and Schindler devised their flexible gastroscope they called it an "entirely safe" instrument (Schindler, 1932). They claimed there was no risk of lower oesophageal perforation, which had been the chief disadvantage of the older rigid gastroscopes. This claim appears to have been justified by later experience, and, to our knowledge, no instance of lower oesophageal injury with the flexible gastroscope has been reported. Other accidents, however, have occasionally occurred. Schindler (1940) published the results of a survey of 22,351 gastroscopies performed by many gastroscopists of varying experience in America. In this large series only one death had occurred after gastroscopy. This was due to hypopharyngeal perforation of the oesophagus. There were also eight instances of gastric and one of jejunal perforation without fatality. Later Schiff and Shapiro (1941) reported a further non-fatal case of gastric perforation. These perforations were attributed to the use of the sponge-rubber tip to the instrument, and no further cases of gastric perforation have been reported since the rubber finger-tip and plain metal end to the instrument have come into general use.

Since this large series was published three further cases of hypopharyngeal perforation with the flexible gastroscope have been reported—Paul and Lage (1943), Touroff (1941), and White (1941). One of these was fatal. So far as we are aware these are the only cases of a dangerous sequel to the passage of the flexible gastroscope that have been published.

Personal Experience with the Gastroscope

In a combined experience of 2,800 gastroscopies, about half of which were done with the Hermon Taylor gastroscope, we have had two fatalities attributable to gastroscopy and four cases that gave rise to some anxiety. We consider it right to publish details of these cases.

Case 1 (Central Middlesex County Hospital).—A woman aged 59. Admitted with diagnosis of scurvy. Considerable improvement after six weeks' treatment with full diet and ascorbic acid, and all cutaneous haemorrhages had disappeared. Gastroscopy was carried out to exclude malignant disease of the stomach. The Hermon Taylor gastroscope was used with a rubber finger-tip. The instrument was introduced as far as the cardia without any difficulty, but the patient had a slight kyphosis and the instrument was held up here. It was then passed on with slight difficulty by active flexion of the end of the instrument. An atrophic gastric mucosa was seen. The patient did not complain of unusual discomfort at the time, but was rather drowsy as a result of premedication with morphine gr. 1/6 and hyoscine gr. 1/150. She remained drowsy and unwell, and that evening surgical emphysema of the neck was noticed and the pulse rose to 130. She was treated with rectal fluids and sulphapyridine by mouth. Her general condition remained poor and swallowing was difficult and painful. An empyema developed on the right side and she died on the sixth day after gastroscopy. At necropsy a longitudinal tear, 1/2 in. long, was found in the posterior wall of the oesophagus, 2 in. from its upper end.

Case 2 (at a South London Hospital).—A woman aged 59. Admitted with diagnosis of gastric ulcer. The patient had been gastroscoped uneventfully three weeks previously by another gastroscopist, using the Wolf-Schindler instrument with a rubber finger-tip. On the present occasion the Hermon Taylor gastroscope with a plain metal end was used. The instrument was passed easily as far as the hypopharynx, where it was held up and did not slip on into the oesophagus when the patient swallowed. Slight pressure was applied, and the instrument passed on about 1 in. The patient then complained of pain localized to the upper thoracic spine. On looking through the gastroscope after one bulbful of air had been injected, a mass of froth was seen instead of oesophageal mucosa. The instrument was immediately withdrawn. Skiagrams of the neck showed surgical emphysema, which became obvious clinically shortly afterwards. The patient was treated with intravenous fluids and sulphathiazole. She remained very ill, with fever and dyspnoea, but without pain after the first 12 hours. She developed a right-sided empyema and died 12 days later. At necropsy a longitudinal perforation of the posterior wall of the oesophagus was found at the level of the cricoid cartilage, with suppurative mediastinitis and extension of the infection to the right pleural space. In the stomach there was a carcinomatous ulcer with secondary lymphatic deposits.

Both these fatalities may be said to be due to an error of judgment. In the first case gastroscopy was probably contraindicated, since the patient's tissues might have been expected to be in a fragile state as a result of her recent scurvy. No difficulty was experienced in getting the instrument past the site of the oesophageal tear. It is possible that the tear was the result of stretching the oesophagus by the rigid part of the instrument, since the patient had a slight kyphosis. In the second case extra pressure was exerted when the tip of the instrument was lying in the hypopharynx. When the patient swallows, the instrument should always slip on easily into the oesophagus, and it is clearly dangerous to apply any pressure if it does not do so.

Case 3 (at a North-East London Hospital).—A woman aged 62. Diagnosis: rheumatoid arthritis; dyspepsia with achlorhydria, but without radiological abnormality in stomach or duodenum. Gastroscopy was carried out to exclude malignant disease of the stomach, and was unusually easy. The Hermon Taylor gastroscope was introduced without any difficulty, and afterwards the patient sat up and commented on the complete absence of any discomfort. The gastric mucosa was atrophic, with erosions and the scar of a healed ulcer. The patient remained well for the next 12 hours, when she developed a slight sore throat and a little fever. This soreness increased, and 24 hours after gastroscopy she had severe substernal pain with dysphagia. Very slight surgical emphysema was detected in the neck and confirmed by skiagrams. She was treated with rectal fluids and intravenous sulphathiazole, and after a febrile course of one week made an uninterrupted recovery. We thought that she might have had an oesophagitis due to an allergic sensitivity either to the rubber sheath of the gastroscope (as in respirator dermatitis) or to the anethaine which had been used as a local analgesic, but skin tests with both these substances gave negative results. In view of the surgical emphysema it must be concluded that the patient had had a small oesophageal abrasion with a subsequent oesophagitis, but it is remarkable that such an abrasion could have been inflicted without any difficulty, pain, or even discomfort at the time of instrumentation.

We have had 3 other cases in which severe retrosternal pain and fever followed gastroscopy, without the development of surgical emphysema. These resolved uneventfully after 7 to 10 days' conservative treatment.

In addition to these cases of our own we have heard of five other fatal and two non-fatal cases of hypopharyngeal perforation of the oesophagus by the flexible gastroscope during the past two years. The Hermon Taylor gastroscope was used in five of the seven fatal cases.

Comment

Gastroscopy with the flexible gastroscope is proving to be an indispensable means of diagnosis of diseases of the stomach, and is rapidly becoming a routine procedure in almost every large hospital in the country. It is inevitable that many gastroscopies should be performed by inexperienced gastroscopists. We believe that some beginners have a false sense of security in their use of the instrument, based on the rarity of reported accidents. Both of our fatal cases were the result of over-confidence in the safety of the flexible gastroscope, which led, in Case 1, to the gastroscopy of an unsuitable subject, and in Case 2 to slight pressure being used to overcome resistance during the passage of the instrument. With our present realization of the risks of gastroscopy both these fatalities would probably have been avoided.

It is important that all users of the flexible gastroscope should realize that there is a slight but definite risk associated with the passage of the instrument, and that in this, as in all endoscopic methods, the greatest circumspection is needed. The main risk appears to be that of perforation of the upper part of the oesophagus and the hypopharynx. Both of our fatal cases, and three of our four cases of severe oesophagitis, occurred in elderly women, which might suggest that such patients carry a special risk; but Touroff's case was in a man aged 40, White's case was in a man aged 58, and two of the unreported cases were in young men. Schindler (1943) has criticized the Hermon Taylor gastroscope, which was used in both of our fatal cases, because of its long rigid portion, which might lead to dangerous stretching of the lower end of the oesophagus as it turns to the left just above the cardia. No accident of this kind has come to our knowledge. The flexible part of the Hermon Taylor gastroscope is 2 mm. wider (i.e., 14 mm. wide) and is appreciably stiffer than the corresponding part of the original Wolf-Schindler instrument. It is possible that extra care is necessary for its passage into the oesophagus. The Hermon Taylor model gives a much better view of the stomach than can be obtained with the Wolf-Schindler instrument, and we consider it is the gastroscope of choice provided it is passed with care.

Summary

Two cases of fatal hypopharyngeal perforation of the oesophagus with the flexible gastroscope are reported.

This accident appears to be the most serious risk of gastroscopy with the flexible gastroscope, and is not so infrequent as the rarity of reported cases suggests.

It is important that inexperienced gastroscopists should appreciate that caution is necessary in the passage of the flexible gastroscope.

TREATMENT OF DENUDED EXTERNAL TABLE OF THE SKULL

BY

PATRICK CLARKSON, F.R.C.S.
Major, R.A.M.C.

AND

J. SCHORSTEIN, F.R.C.S.
Major, R.A.M.C.

(Surgical Specialists and O.C.s Army Maxillo-facial and Neurosurgical Units)

This note describes a method of treatment of areas of bare external table exposed in deep burns and extensive injuries of the skull. It has been found satisfactory in the three cases in which it has been used. All these cases had complete loss of scalp and pericranium over the exposed bone, which was dry and eburnated.

The classic treatment for this condition is to make burr-holes through the exposed bone into diploe; to await the appearance of granulations from the burr-holes and their coalescence across the intervening outer table; and then, when the layer of granulations is complete, to cover it by a free graft. The particular disadvantage of this method is the delay between the operation to expose patches of diploe and final healing. The granulations may be slow to appear and slower to coalesce completely; 6 to 12 weeks may elapse between the initial operation and final healing of the free graft. It is clear that if skin can be made to stick consistently on freshly exposed diploe much time can be saved.

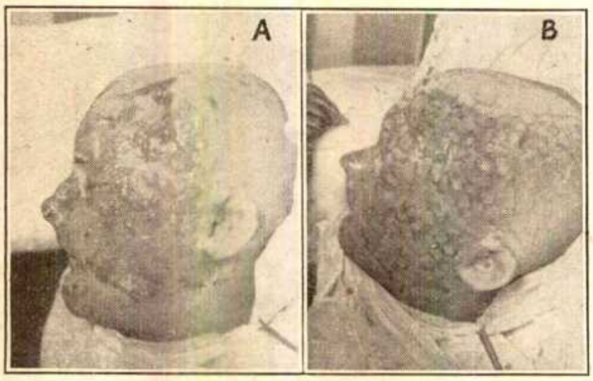

FIG. 1, Case 1.—(A) Contact burn destroying skin of face, nose, and forehead, and exposing 8 by 6 cm. of the external table of the frontal bone. (B) On the 24th day the external table was removed and the exposed diploe, together with face, forehead, and nose, was covered by thin patch grafts. Healing was complete six days later.

During the Cassino battle a case of direct-contact burn was admitted with destruction of part of the scalp, the forehead, one cheek, and half the nose. After clearance of sloughs, 8 by 6 cm. of frontal outer table was exposed. On the 24th day primary re-surfacing by patches was undertaken. These were closely packed over the soft parts, and it was decided to cover the bare skull at the same operation. The exposed outer table was totally removed and thin split skin applied directly to the diploe. The grafts took completely, and the whole skull, together with forehead, cheek, and nose, was healed by the 30th day. This patient has been under observation for 8 months during the late repair of his nose and cheek. The skin over his diploe has remained stable; the depression in the skull caused by removal of the outer table is slight and not easily noticeable; palpation of the area suggests a thin deposit of subcutaneous tissue between graft and diploe.

Technical Points

Burr-holes are made through the exposed outer table into diploe and connected by a groove made by a gouge. Small areas of outer table are thus enclosed and taken off with an osteotome. Near the sagittal sinus arachnoidal granulations might be lacerated; if they were, the bleeding could be easily controlled with a small muscle graft. The intervening bone between the burr-holes and back to the margin of the granulations is completely removed. When there is comminution of the outer table near the margin these flakes are removed together with overlying granulations. Haemostasis is obtained by pressure with hot packs. Wax was used in one case without apparent prejudice to the graft.

The cover is provided by thin patch grafts, 1 cm. square, packed close and spread on grease-proof paper. A well-incised thin sheet stuck on with sano extracts or gum acacia would probably be almost as certain to take. The grafts are fixed by tulle gras, P.F. wool, wool, and crêpe. The dressings are taken down at the fourth day and repeated daily with a careful technique. Crêpe pressure is maintained until final healing.

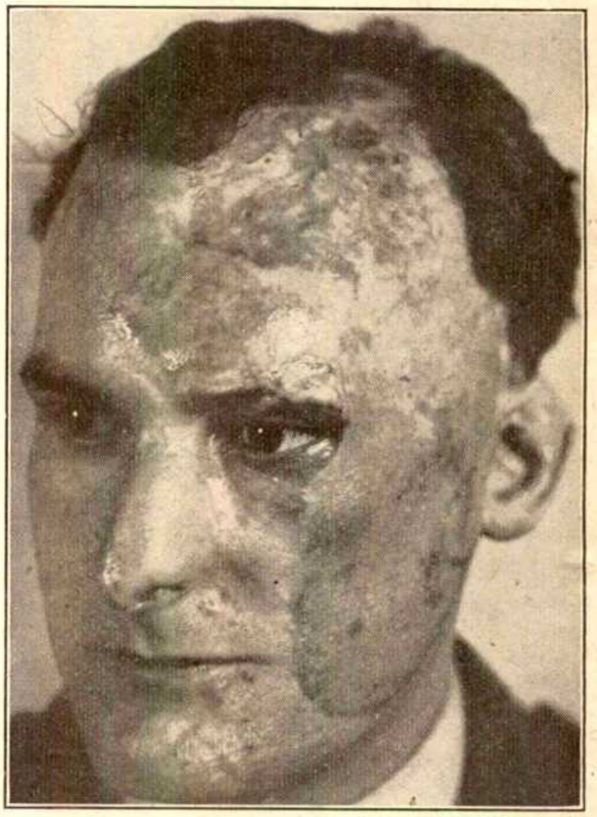

FIG. 2, Case 1.—The appearance of the skull eight months later. There is a shallow depression where the external table was removed. The diploe is covered by skin, which has been stable during exposure to Mediterranean sun and to cold. (The nose has been repaired by a forehead rhinoplasty, and the patch grafts on cheek and forehead replaced by thick dermatome sheets from the abdomen.)

Results

The accompanying Table shows that exposures of the outer table of 8 by 6, 12 by 10, and 7 by 6 cm. were healed in 6, 10, and 20 days respectively after removal of the whole of the exposed external table and immediate application of free grafts. The delay in healing in the mine wound (20 days after operation) was attributed to the presence of osteitis in the external table at margins of the defect.

Table showing Type of Case treated

Case	Site and Size	Cause	Day Grafted	Day Healed	Comment
1	Frontal, 8 by 6 cm. (Figs. 1 and 2)	Contact burn	24	30	Soundly healed throughout 8 months' observation
2	Frontal, 7 by 6 cm.	Mine	67	87	Extensive dirty multiple mine wounds. Gravely ill for many weeks before operation. Some osteitis of comminuted exposed external table. Case treated with Major Tutton, R.A.M.C.
3	Parietal occipital, 12 by 10 cm.	Electric burn	60	70	Had over 1,000 sq. cm. of full-thickness skin-loss of back also re-surfaced with patch grafts. Skull treated by Capts. Grossman and Jepson, R.A.M.C.

PERSPEX IN ORTHOPAEDICS

BY

JOHN T. SCALES, M.R.C.S., L.R.C.P.
Lieut., R.A.M.C.

AND

WOOLF HERSCHELL, M.B., Ch.B.
Assistant Surgeon, E.M.S.

The suitability of plastics in orthopaedics has been under investigation at the Royal National Orthopaedic Hospital for some months, and this is an interim report on the work so far carried out. Methods previously used have involved the making of a positive from a negative plaster cast, and to this positive, perspex has been moulded. In order to reduce the time involved in the preparation of positive casts, a method was sought which eliminated this procedure. It has been found quite easy to make small moulded splints direct from the negative by hand. For large splints, however, the hand method was not adequate, and an apparatus was designed which could accurately mould the material to the large negative cast. For this type of moulding compressed air was found the most suitable means of applying pressure to the material.

Advantages of Perspex.—(1) Easy moulding by heat. (2) Light weight. (3) Durability. (4) Light-transparent, including ultra-violet band. (5) Permeable to *x* rays. (6) Cleanliness. (7) Waterproof—not affected by urine, etc. (8) Unbreakable—within limits. (9) Non-irritant to skin. (10) Reclaimable—material can be used again after reheating.

Disadvantage of Perspex.—Non-porous (see later).

It will be seen that this material offers many advantages over plaster-of-Paris, inasmuch as its durability, cleanliness, and light weight are features which have long been sought when patients are being treated for considerable lengths of time in orthopaedic splints. A patient can be nursed adequately, cleanly, and comfortably in a perspex shell without the disadvantages of softening by urine, reinfection of sinuses or wounds, and distortion or collapse of the shell, which are so often found when plaster-of-Paris shells are used. Moreover, for patients who cannot be moved—e.g., fractured spines—skiagrams can be taken *in situ*.

Method for Making Small Splints.—Suitably thick material (1/16 to 1/8 in.) of appropriate size is heated, pressed by hand into the negative cast (using asbestos gloves), and held until cool. The splint is trimmed with an electric saw, and the edges smoothed before fitting to the patient.

Method for Making Large Splints (Including Anterior and Posterior Shells).—A plaster cast of the part required, with 2-in. to 3-in. flanges on each side, is made (Fig. 1), and this is then placed in the lid of the moulding apparatus (Figs. 2 and 3).

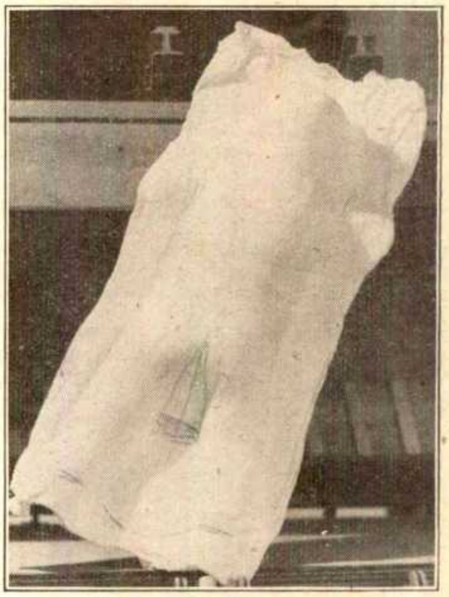

FIG. 1.—Plaster cast for perspex shell with 4-in. flange.

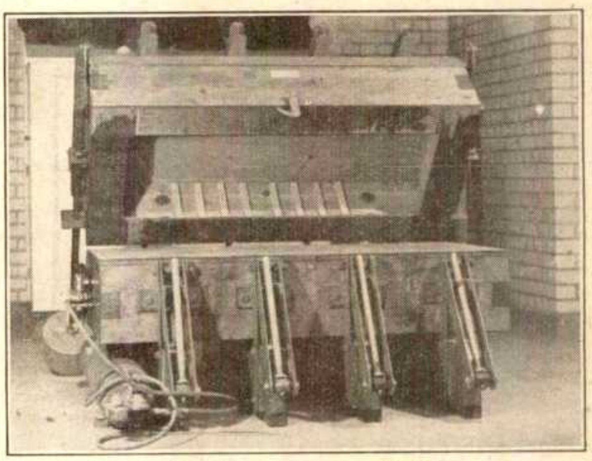

FIG. 2.—Moulding apparatus with lid open.

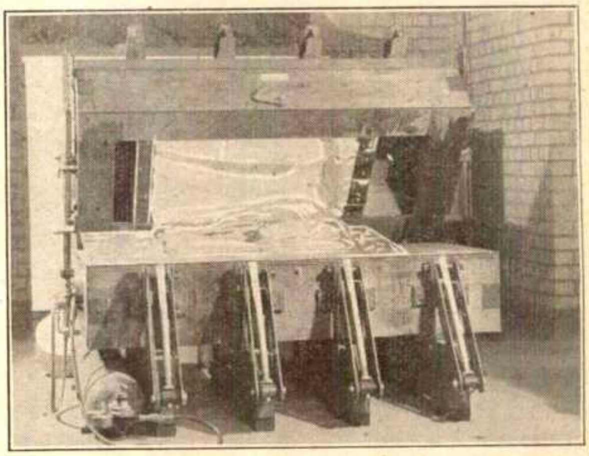

FIG. 3.—Moulding apparatus opened after perspex mould has been blown. Plaster cast seen in lid and mould lying on base.

The remainder of the compartment is packed with sandbags (Fig. 4). The perspex sheet (1/8 to 3/16 in. thick), having been previously softened in an infra-red oven, is laid on the base of the apparatus and the lid clamped down. Air pressure is applied (15 to 20 lb. per sq. in.), which forces the perspex into accurate contact with the cast. The air pressure is maintained for a short while to allow the perspex to cool, and the perspex mould is then removed from the apparatus (Fig. 3).

Mounting of Perspex Shells.—These are mounted in standard adjustable frames which, when the shell is discarded, can be used again. After cutting out the apertures for limb and toilet requirements the mould should be suspended from the frame by turning the remaining part of the flanges over the upper bars (Figs. 5 and 6).

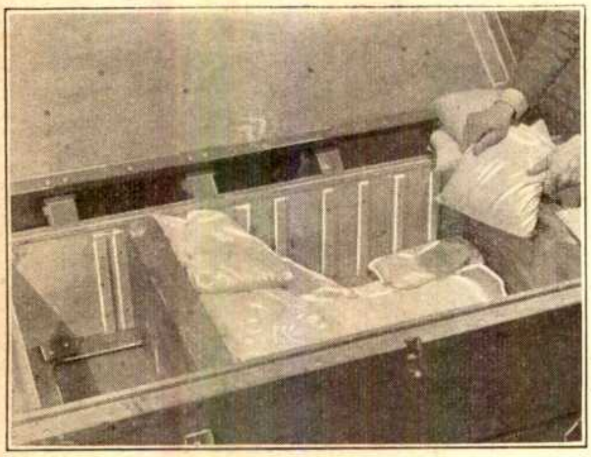

FIG. 4.—Sandbags being packed over plaster cast in lid of moulding apparatus.

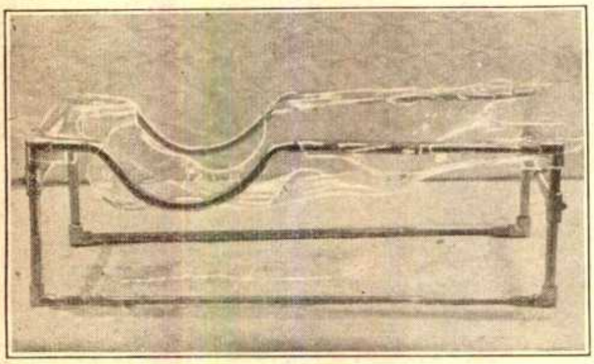

FIG. 5.—Perspex shell mounted on standard adjustable frame, showing suspension of shell.

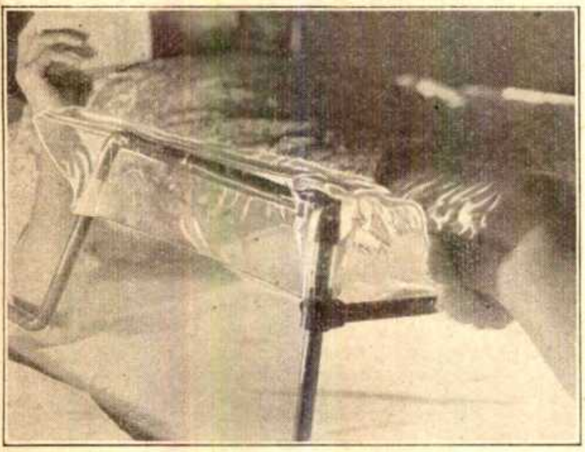

FIG. 6.—Adult patient being treated in perspex shell.

Observation.—It might seem that the method of pressing perspex into negative casts will reduce the diameter of the splint by double the thickness of the material used. It has been found that, while this is theoretically the case, in fact the "spring" in the material largely compensates, and a snugness of fit is obtained which is an improvement when compared with plaster-of-Paris casts.

Some Notes on Technique in Handling Perspex

1. The disadvantage of the material being non-porous can be overcome by drilling small ventilation holes in any area where moisture is likely to accumulate.

2. Cutting.—A high-speed saw is essential, otherwise the material is liable to fracture. Care must be taken that no saw cuts are left in the edge of the finished splint, otherwise stresses will cause such cuts to run into cracks. When an area has to be removed from the body of the splint large-diameter drill-holes should first be made at the apices of the intended meeting-point of the saw cuts.

3. Edges.—After cutting, all edges should be smoothed with a file or burred, and then sandpapered.

4. If local alteration in shape is required the area should be carefully flamed with a Bunsen burner on both sides till it softens, and then moulded by hand.

5. Cleaning and sterilization.—Cleaning should be done with soap and water (not boiling) or with cetavlon. After this the splints may be polished with any metal polish. Such cleaning agents as ether, benzine, chloroform, and xylol should not be used, as these are solvents.

6. Various methods of heating have been tried, but it has been found that the most satisfactory way is with radiant heat or infra-red ovens. These adequately soften the whole material, without overheating the surface.

Perspex splints are being used for cases of tuberculosis of the spine, osteomyelitis of the sacrum, anterior poliomyelitis, fractured spine, and Still's disease, and have been found most suitable. They are preferred by patients to plaster-of-Paris splints.

Our thanks are due to the Royal National Orthopaedic Hospital for allowing us to carry out this experimental work, and to Mr. J. A. Cholmeley and Mr. E. P. Brockman for their encouragement and help. We are indebted to the Triplex Safety Glass Company for the design and presentation of the moulding apparatus, and particularly to Mr. Anstey and Mr. Chart, for whom no trouble has been too much; to Messrs. British Thomson Houston, Watford, for the presentation of the heating equipment; to Imperial Chemical Industries Ltd., for a research grant and material; and to Mr. Desoutter, of Desoutter Bros., for technical help and advice.

USE OF THE CAUTERY IN PLASTIC OPERATIONS ON THE EYELIDS

BY

D. SIMPSON, M.B., Ch.B., B.Sc.

Surgeon, Bristol Eye Dispensary

The following technique used by me in some plastic operations on the eyelids may be of interest. The results are obtained with the electric cautery alone or in combination with the scalpel, but the major part of the work is done with the cautery. So far as I know the method is not commonly practised, and the subject appears to receive less attention than it deserves from the majority of ophthalmologists. This short paper does not deal with the causes of the conditions found, but only with their repair.

Conditions Dealt With

The main types dealt with are: ectropion, entropion, symblepharon, distichiasis, and ptosis. The aim is to produce just enough contracture, by scarring in the underlying tissue, to cause the lids to assume a normal position. I use the ordinary Weiss cautery, and the size of point used will vary with the condition—from 5 mm. to 1 cm. long and 2 mm. to 1/2 mm. wide at the base. It is astonishing how little scarring the skin and conjunctiva suffer, even after very vigorous treatment.

Perhaps the commonest condition met with is *entropion* of the lower lid. An injection of 2% novutox along the whole length of lid secures analgesia; a point 1 cm. long and 2 mm. broad at the base is selected, and sufficient current to make it red-hot along its whole length is applied. The point is pushed through the skin down to the base of the tarsal plate, 4 mm. below the lid margin. This is done five or six times along the whole length of the lid. The point is held in each puncture about three seconds. No dressing is necessary and the puncture wound heals in about five days. The patient is given boric lotion and cotton-wool to wipe away secretion, but I doubt if even this is necessary.

In mild *ectropion of the lower lid* the same technique holds, except that one applies the point inside the lid and directs it below the tarsal plate down into the connective tissue. The lid can easily be maintained with ordinary forceps. If the condition has been present for a long time and is fairly prominent, it is necessary to excise a longitudinal strip of conjunctiva, usually about one-third the width of the exposed membrane, taking the middle third. The amount taken, however, is largely to be determined by the condition present, and it may be necessary to go higher or lower. The red-hot point is then plunged deeply into the exposed tissue, going below and beyond the tarsal plate, in more places than would be used for entropion, and it is necessary to go beyond the limit of the ectropion. One is not likely to cause the contrary condition, and so it is advisable to be thorough. A drop of argyrol 5% and sterile liquid paraffin is then instilled and the eye kept bandaged for 3 days. The drops are repeated each day, of course. The two edges of the conjunctiva rapidly come together, and there is seldom any break in the continuity after 10 days.

Ectropion of the upper lid is usually more severe and requires to be done thoroughly. The middle third of the conjunctiva is resected along the whole length of lid and the red-hot point is plunged deeply into the connective tissue, to and beyond the tarsal plate, at a sufficient number of places. There is usually quite a lot of haemorrhage after the conjunctiva has been resected, but if the lid is controlled with forceps an assistant with swabs can keep the field fairly clear. The application of the cautery soon stops all bleeding. Argyrol 5% and liquid paraffin are then dropped in, and it is advisable to pass a stitch from upper lid to cheek. This stitch may remain for three days. Thereafter argyrol for a few days more will usually suffice.

Symblepharon is a difficult condition to treat by the usual methods and often recurs. I have only attempted to disengage adhesions, not to cure the condition, when the cornea is invaded. In addition to drops, some cocaine is injected subconjunctivally. The cautery is then applied to divide the adhesions at the most suitable spot, the point being carried down to the sclerotic. Each adhesion is thus treated and the usual argyrol and liquid paraffin instilled. It is seldom that the adhesions reunite.

The treatment of *distichiasis* and *trichiasis* by electrolysis is a long, laborious, and not very successful business. I have been able, with the cautery, to do both lids of an eye at one sitting of about 10 minutes, and the result proved satisfactory. The lids are anaesthetized with novutox and a drop of cocaine placed in the eye. Then a point 5 mm. long and as narrow as possible is used. I always employ the loupe to get a good view of where the point is going. This is used red-hot and pushed down each hair follicle in turn. It must be pushed down its full length and retained for two seconds. The lashes do not grow again and no damage is done to the lid margins.

I have treated a few cases of *congenital ptosis* in children, and if the results have not been brilliant they have at least been satisfactory in leaving the pupil exposed. The principle is to cause the levator to form fresh adhesions to the tarsal plate. The child will require a general anaesthetic, as it will not submit otherwise. A row of six punctures is made just above the tarsal plate, then going into each puncture again, passing the point upwards this time, and in the subcutaneous tissues as far as it will go. The point should be 1½ cm. long. No dressing is necessary, and in fact is inadvisable. I have also dealt with a variety of other conditions, of little consequence, such as warts, which are simply and permanently removed with the cautery.

I hope I do not give the impression of brandishing my cautery at every patient I see. I merely describe it as a very useful procedure in many conditions; it is not generally realized how simple and useful it can be. In my own practice the results are in almost every case superior to those of the scalpel and stitch. I have been practising it now for a number of years.

S. Zelman (*Amer. J. med. Sci.*, 1944, **207**, 461) determined blood diastase values in a series of 89 cases of mumps, on admission to hospital and on discharge, with the following results: 73% were above normal on admission and 9% on discharge; 3% were subnormal on admission and 20% on discharge; 15% of this series showed evidence of pancreatitis some time during the course of their illness.

Medical Memoranda

Large Fibroma arising from the Pulmonary Pleura of the Right Lower Lobe

The following case appears to be worthy of publication owing to its rarity and difficulty of diagnosis.

On Aug. 17, 1944, the patient, a man aged 48, consulted his practitioner for pain in the lower part of the right side of his chest on breathing. Examination revealed a dull area at the base of the right lung with weak breath sounds in the area. His temperature was 99.8° F.; he had no cough or sputum. A diagnosis of fluid was made. The basal sedimentation rate was found to be 32 mm. in one hour. His area of dullness increased rapidly, and three days after he was first seen he was screened and a large shadow was observed to move on respiration. It lay in the posterior part of the chest, above the diaphragm. Fluid was also present, and 20 c.cm. was aspirated and sent for pathological examination. It showed numerous endothelial cells, many of which were undergoing mitosis, and the pathologist suggested that these might be malignant in origin because of this. A tentative diagnosis was made that the tumour might be an endothelioma. Removal of another large collection of fluid caused a great deal of pain, presumably because the tumour was now rubbing against the thoracic wall. It soon ceased as the fluid reaccumulated. This rather tended to support the diagnosis of a malignant tumour.

The man was admitted to the Royal Infirmary, Sheffield, on Sept. 8 and was referred to me for further investigation. A thoracotomy was performed, and on opening the chest a large tumour was found occupying the lower part of the right pleural cavity. It was very nearly spherical, and was lightly attached to the parietal pleura on the one hand by a few adhesions, but arose from the visceral pleura, from which it received its blood supply. Only slight effort served to separate the tumour from the parietal pleura, and it at once fell back into the thoracic cavity. Owing to its size (12 cm. in diameter) it was difficult to manipulate, and it was necessary to resect a portion of a rib in addition to dividing another. On pressing the tumour into the wound from the thorax it shot through the opening in the chest wall and tore itself free from the lung. There was a little bleeding from the area of attachment, which was circular and measured 5 cm. in diameter. The lung was sutured and no further bleeding occurred. The man made an uninterrupted recovery and was able to go home a fortnight later.

The figure is from a photograph of the specimen after removal. The pathological report is that it is a simple fibroma undergoing hyaline degeneration.

I am indebted to Dr. George Herbert of Worksop, who sent the case to me and who also primarily investigated it; and to Dr. L. C. D. Hermitte, of the pathological department, Royal Infirmary, Sheffield, for the pathological notes and photograph.

A. W. Fawcett, F.R.C.S.,
Honorary Surgeon, Royal Infirmary, Sheffield.

An Unusual Case of Ruptured Aortic Aneurysm

Syphilitic aortitis with rupture of a large saccular aneurysm of the abdominal aorta into the stomach is so rarely seen that it was considered justifiable to add the following to the large number of cases of ruptured aortic aneurysm described in the literature.

Clinical History

A civil servant aged 60 was admitted to the Essex County Hospital, Wanstead, on Feb. 16, 1943, complaining of pains in his shoulders, back, and legs; he also had difficulty in swallowing and had lost weight. The pain in his back was of a continuous drawing nature, but he had shooting pains down both legs, accompanied by occasional swelling of his knee- and ankle-joints. He had also noticed some weakness and unsteadiness of his legs. For the past two months he had complained of difficulty in swallowing solids, vomiting almost at once, but he was able to manage fluids and soft foods such as porridge. He lost 2 st. in weight in three months.

On examination he was found to be a very thin, wasted man. His tongue was clean and moist, his throat was normal, and there was no enlargement of his lymphatic glands. No oedema was seen. His pulse was regular, slow, and slightly collapsing. His apex beat was in the midclavicular line and no thrill was palpable in the mitral or aortic areas. Loud blowing systolic and diastolic murmurs were heard over the praecordium, loudest in the aortic area. Tracheal tugging was absent. His blood pressure was 115/70. Nothing abnormal was found in the lungs and the abdomen. A careful examination of his central nervous system did not give any abnormal physical findings. A skiagram of his chest revealed a large bulge on the right side of the heart shadow which suggested an aneurysm of the aortic arch. Cardioscopy showed a pulsatile aortic aneurysm affecting the aortic arch and thoracic aorta and displacing the oesophagus to the left. It thus caused narrowing and obstruction of the oesophagus, which could be well seen when the patient was given some barium. His left ventricle was much enlarged. The Wassermann reaction was strongly positive.

On Feb. 27 the patient developed diarrhoea, and blood was seen in the motions. On March 4 he suddenly collapsed, complaining of pain across the front of his chest He was pale and shocked, and his pulse was imperceptible. He died shortly afterwards.

Necropsy.—Acute adhesive pericarditis was present, obliterating the pericardial sac and giving rise to the typical "bread-and-butter" appearance. No pericardial fluid was found. The left ventricle was hypertrophied but not dilated. The mitral, tricuspid, pulmonary, and aortic valves were normal and the openings of the coronary vessels were patent. Half an inch above the aortic valves the beginning of syphilitic aortitis with aneurysm formation was seen. The aneurysmal dilatation extended along the whole course of the aortic arch and descending thoracic aorta down to the first two inches of the abdominal aorta. It was mainly tubular, but one large saccule full of laminated clot extended into the right lung from the aortic arch. In front of the first two inches of the abdominal aorta a saccular aneurysm, the size of a large orange and full of laminated clot, was seen. This aneurysm was pressing anteriorly against the posterior aspect of the left lobe of the liver, indenting it and forming part of the stomach bed. The oesophagus was markedly deviated to the left and compressed in its lower third by the aneurysmal dilatation of the thoracic aorta. On opening the stomach it was found to be full of blood clot. An area the size of a sixpence on the posterior wall of the fundus of the stomach was adherent to the large saccular aneurysm of the abdominal aorta, which had perforated into the stomach in this area. The intestines were normal. There was fluid in both pleural cavities. Many pleural adhesions which could be broken down only with difficulty were seen. The pleurae were thickened over the lower lobes. Both lungs were congested, but no evidence of pneumonic consolidation was found. The spleen was slightly enlarged and was soft. The kidneys and suprarenal glands were normal. The liver showed signs of venous congestion and fatty degeneration.

Dr. Gilmour reports: "Portion of aorta showing syphilitic aortitis. Portion of clot from aneurysm of abdominal aorta adherent to stomach wall containing many streptococci in one place. Portion of stomach with cardiac orifice showing acute and subacute pyogenic inflammation, intense on the outer surface of the stomach and oesophagus and in a small portion of the diaphragm attached. Nothing was seen to suggest a syphilitic inflammatory process." The perigastric inflammation must have preceded the final perforation of the thin stomach wall overlying and adherent to the saccular aneurysm.

Essex County Hospital, Wanstead. E. FRANKEL, M.D., M.R.C.P.

Small-bowel Obstruction due to Dried Fruit

The following case of small-bowel obstruction may be found of interest.

The patient, a woman aged 60, was admitted on May 14, 1945, with the history of a sudden onset of abdominal pain and vomiting the previous day. The pain was colicky in nature and vomiting had persisted up to the time of admission. The bowel action had been quite regular until the previous evening. There was a history of acute appendicitis many years before, and following appendicectomy five abscesses in the scar had occurred.

On examination her temperature was 99.8°, pulse 120, and respirations 28. She was well nourished and not particularly dehydrated. The cardiovascular system was normal, but there was evidence of well-marked bronchitis. The tongue was coated. The abdomen was somewhat distended and showed an old adherent appendix scar. There was marked tenderness in both hypochondria and over a point at the left of the umbilicus, with guarding and audible peristalsis. Rectal examination revealed nothing abnormal. A diagnosis of small-bowel obstruction was made, thought possibly due to bands in the region of the old scar.

Laparotomy was performed through a right paramedian incision. On opening the peritoneum the omentum was found to be adherent to the old scar, but the small bowel, which was distended, was not involved. The distended small intestine was traced down to within two feet of the ileo-caecal valve, where a fusiform mass about 3 in. long filled the lumen. The gut below this was collapsed. The bowel was opened and the mass removed, the incision repaired, and the abdomen closed. She was discharged after an uneventful convalescence on June 5, 1945.

Examination of the object revealed it to be half a dried apricot, which was folded over on itself. Later questioning of the patient disclosed that eight days before admission she had been bottling some apricots and "may have eaten one or two." She wears artificial dentures.

Victoria Hospital, Worksop.

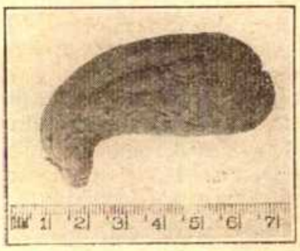
Acute Intestinal Obstruction due to Dried Fruit

This form of intestinal obstruction seems to be a post-war risk, judging by the cases recently recorded. In this case the obstruction was caused by a dried peach.

CASE REPORT

An edentulous old lady aged 64 was admitted to Hammersmith Hospital on May 18, 1945. Six days previously she had eaten dried peaches. As she had no teeth she had sucked the peaches before swallowing. She denied having gulped down any large piece. Four days later she was seized with colicky umbilical pain and began to vomit. This continued until her admission after a further two days. She then presented a picture of acute low small-intestine obstruction. Visible and palpable peristalsis was present in the centre of the abdomen. After a pint of intravenous saline and gastric aspiration by Ryle's tube, the abdomen was opened under regional block analgesia supplemented by nitrous oxide and oxygen. The small intestine was grossly distended. In the lower ileum about 18 in. from the ileo-caecal valve a firm object the size of a peach was felt. It was at the usual site of a gall-stone obstruction, but was not hard enough for a calculus. I could not push it on into the caecum through the contracted ileum below, but it was easily pushed back into the distended coils above. When it had reached a healthier portion of the ileum this was shut off with light intestinal clamps and incised vertically over the object, which was removed and the bowel sewn up transversely in two layers. The abdomen was closed in the usual way. The patient has made an uninterrupted recovery.

The object was yellow and of the characteristic size and shape of a dried half-peach (see photograph).



Peach removed from ileum

COMMENTARY

Elliot (1932) reviewed the cases reported during the previous 22 years and gave the following table:

Obstructing Material	Cases	Obstructing Material	Cases
Mushrooms	5	Poppy seeds	2
Cherry stones	4	"Ammunition bread"	1
Beans	4	Sauerkraut	1
Figs	3	Gooseberries	1
Oats	3	Raisins	1
Potatoes	2	Half an orange	1
Apples, pears, peas	2	Popcorn	1
Corn	2	Bran	1
Grapes	2		

Latchmore (1940) in an article on the cause of "ordinary stomach-ache," which he considers is usually due to bolus colic of the small intestine, reported four cases which required emergency operations for the removal of monkey-nuts, almonds, portions of coconut, and three segments of an orange. No fewer than five cases were recently reported in three papers in the *British Medical Journal* (Jones and Davies, 1945; Lyall, 1945; Radclyffe, 1945)—three due to oranges, one to dried apples, and one to unspecified dried fruit.

It seems that with the release of a considerable amount of dried fruit we should temper our delight with mastication, for the power of dried fruit to swell by the absorption of water is considerable. The risk would appear to be greatest when a portion of unprepared dried fruit is swallowed whole. But there is another risk in the case of edentulous people, who, unable to bite, chew and suck the fruit dry before swallowing. In either case it absorbs fluid in the alimentary canal. It usually has no difficulty in passing through the pylorus and jejunum, but gets held up in the ileum at its narrowest part at the junction of the mid- and hind-gut, one or two feet above the ileo-caecal valve. Often peristalsis is sufficient to pass the bolus on with no more symptoms than stomach-ache (bolus colic of Latchmore). Sometimes at operation it is possible to push the mass on into the caecum. Rarely, as in the case here reported, it has to be removed by enterotomy.

Reviews

CLINICAL ELECTROCARDIOGRAPHY

Clinical Electrocardiography. By David Scherf, M.D., and L. J. Boyd, M.D., F.A.C.P. Second edition, revised. (Pp. 403; illustrated. 25s.) London: William Heinemann. 1945.

This small book, now in a second revised edition, contains a good deal of valuable information. The general arrangement is on the usual lines. It will be noted that the point of view tends to reflect the approach and experience of the Viennese and French schools, particularly the former, and the result is that a good many opinions held in this country and in the United States do not find expression.

The authors do not accept the theory of circus movement as an explanation of auricular fibrillation and flutter, but regard it as not yet established. They are inclined to hold reserved opinions on the interpretation of the curves of bundle-branch block. They prefer to speak of a common or a rare type, and not to accept the new terminology which locates the more common lesion on the left side of the septum. They doubt whether reduplication of the first sound is ever caused by asynchronous contraction of the ventricles. They hold that the curves showing wide, notched mitral deflections in the ventricular complex are due to arborization block; these are thought to indicate widespread severe lesions in the ventricles, and they believe that the differentiation from the local lesion of bundle-branch block is important. There is a full discussion of chest leads, and a clear account of the various technical difficulties and discrepancies which cause confusion at the moment. Scherf and Boyd prefer to use C R_2 and C R_4, but are cautious, for they regard the value of chest leads as exaggerated.

This book is well worth study, and even if the conclusions are not acceptable the discussion is full, fair, and stimulating. The illustrations for the most part are clear, though some are faint and indistinct, with an obsolete method of time-marking.

INTRAVENOUS THERAPY

Intravenous Therapy. By K. V. Thakkar, L.M.&S. Second edition; revised and enlarged. (Pp. 349; illustrated. Rs. 8/8.) To be obtained from the Kothari Book Depot, Parel, Bombay, 12.

This book begins with a description of apparatus, methods, and dangers of intravenous injection, and then follow chapters on arsenical therapy, blood transfusions, intravenous drip, intravenous anaesthesia, and intravenous injection of drugs. The book serves a useful purpose by gathering together a good deal of scattered information, but it is not up to the standard of English and American textbooks. The typography is clear but there are many misprints. The laudatory forewords to the book and the inclusion of advertisements of proprietary remedies are out of keeping with a scientific monograph. Many of the details about sterilization of syringes and transfusion of blood are not up to date. Apparatus is figured which went out of use in this country ten years ago, and homologous serum jaundice is not mentioned.

The second half of the book is essentially a compendium of details of most of the drugs which have ever been given intravenously. Some of this information is of purely historical interest, and much of it is presented uncritically. There can be little excuse to-day for treating Graves's disease by the intravenous injection of 5 c.cm. of 2% solution of sodium fluoride on alternate days. It is true that the *Extra Pharmacopoeia* mentions the treatment of paralytic ileus by the intravenous injection of 10 grammes of choline chloride in 180 c.cm. of normal saline, very slowly, but we would like to know how slowly; certainly it should not be more than 1 c.cm. a minute. It is not true that iron does not produce toxic effects when given intramuscularly. These, however, are minor blemishes. A more serious fault is the lack of any general consideration of the pharmacological principles of intravenous therapy and the effects on concentration and rate of excretion when drugs are given in this way. In many Eastern countries it is customary for an inclusive fee to be paid for a consultation and an injection, but custom can hardly be the basis for a scientific monograph.

SURGERY OF THE CHEST

Surgical Disorders of the Chest. Diagnosis and Treatment. By J. K. Donaldson, M.D., B.S., F.A.C.S. (Pp. 364; illustrated. 33s.) London: Henry Kimpton.

There is still need for a good and informative book on the surgery of the chest, and many readers eagerly look for one that will fulfil this need. It cannot be said, however, that Dr. J. K. Donaldson's work supplies the want. One striking deficiency is in the quality of the illustrations; the radiographs are particularly disappointing. Good radiographs are essential for the proper presentation of chest diseases.

The book is ill balanced in the amount of space devoted to rare or unimportant conditions; in contrast, the whole field of the surgery of pulmonary tuberculosis is dealt with in less than 70 pages out of 355. Many of the author's statements and conclusions are based on appraisal of the recommendations of others rather than on the authority of his own experience. Some recommendations are startling, such as the dictum that a haemothorax should be aspirated if the chest is still half full of blood after six weeks. Again, the recommendation that simple tuberculous empyema should be treated by needle-aspiration at the lowest level is one that will only tend to repeat the many crops of disasters that have followed this procedure in the past. No other tuberculous abscess in the body is aspirated in the most dependent area. Graham's cautery pneumonectomy is also discussed and advised, whereas to-day it is obsolete and of only historical interest. We agree heartily, however, with the author's statement that although the treatment of tuberculosis has not yet reached perfection the greatest need at the moment is not for improved methods but for a proper and full use of the methods already available.

HEAD INJURIES

Acute Injuries of the Head. Their Diagnosis, Treatment, Complications and Sequels. By C. F. Rowbotham, B.Sc., F.R.C.S. With foreword by Norman M. Dott, F.R.C.S.Ed. Second edition. (Pp. 424; illustrated. 30s. plus 9d. postage.) Edinburgh: E. and S. Livingstone. 1945.

A second edition of this monograph coming two years after the first is a testimony to its popularity. Notable advances have been made in the treatment of head injuries during the war, and although Mr. Rowbotham's book is an expression of the author's own practice and experience he has kept in close touch with new developments, and no important omissions can be found in the many references to recent literature. Several valuable additions have been made, notably in the account of rehabilitation methods, and this should be of as much interest to the general practitioner dealing with a few patients as to authorities responsible for rehabilitation schemes. The author writes in a homely style which is easy to read, but some of the clinical descriptions would be more valuable given in general terms than in single case reports, although the latter may be more interesting. The chapters on technique are clear and well illustrated, so that the general surgeon who is called upon to deal with an emergency should find the answer to most of his problems. For the specialist the book is a useful record of present-day thought and practice and a handy guide to the literature. It is likely to remain the standard British monograph on the subject of head injuries for many years to come.

Notes on Books

For the eighth edition of their popular *Modern Methods of Feeding in Infancy and Childhood* (Constable and Co.; 8s. 6d.) Drs. DONALD PATERSON and J. FOREST SMITH have chosen a new format, and the result is a more compact volume, easy to handle as it is to read. Great revision is obvious, with good use of all that has been learnt of nutrition in recent years. As it approaches its twentieth birthday this book improves upon what always was a sound exposition of an important subject.

Dr. ARTHUR C. GEE in *So You Have a Toddler* (John Wright and Sons, Bristol; 1s., or 10s. 6d. a dozen) follows his success with the ante-natal period and the care of the baby in two previous booklets. More might be said of milk in the diet (and safe milk at that), and it is unfortunate that the chapter on minor ailments starts off with measles and the other infectious fevers. But the approach is sound and helpful, and the stress is rightly on child management and character training. It is a safe book to put in the hands of mothers, and singularly free from fads.

A book on *Semi-Micro Quantitative Organic Analysis*, by R. BELCHER and A. L. GODBERT (Longmans, Green and Co.; 10s. 6d.), describes the apparatus and methods used and approved after selection by the authors from among the various plans of procedure which have been published. As these authors have an unusually large experience in this field, and as they have practised the methods extensively, this book has a special value. The use of semi-micro methods promises to fulfil the needs of an increasing demand, and in addition to the mastery of its accomplishment for its own purposes it provides an easier approach to the use of micro methods proper. The descriptions are lucid and precise and the illustrations are satisfying. It will be found a useful book of reference as well as a sound basis for a course of study.

There is nothing in English literature which takes the place of the German *Zentralblatt für Ophthalmologie*. The lack of these sources during the war years has been a real want, all the more exaggerated by the sudden emergence of problems relating to black-out, offensive air activity, and a whole series of visual difficulties that assumed new and forbidding aspects. The problem was sufficiently acute for the British Air Ministry to ask for the help of the United States Office of Scientific Research and Development in Washington, and of Yale University, in the compilation of a classified bibliography of the literature on the subject. Though belated as a public contribution to the war effort, *A Bibliography of Visual Literature, 1939–44*, compiled by J. F. FULTON, P. M. HOFF, and H. T. PERKINS, is a welcome addition to the bibliographical lists in ophthalmology. It is in no sense an index to the ophthalmic literature during the war years, but in the special field it is invaluable to the research worker. It is issued at $3.00 as Publication No. 11 of the Historical Library, Yale Medical Library.

Letters to a Nurse, by A Midland Doctor (London: Staples Press Ltd.; 3s.), is a fine little book. It would be well if these letters from a doctor uncle to his niece beginning her training in hospital were published by the thousand and supplied to every girl going in for nursing as a career. Every word he writes is true and sound, kindly and understanding, and would be of great help to the somewhat bewildered probationer. He stresses the three essentials to the making of a good nurse. First, it should be her vocation—not just a mode of making a living. Second, good health: a physically and mentally unhealthy nurse cannot bring comfort and health to her patients. Third, unselfishness, sympathy with, and an appreciation of, her patient's condition. He also insists that a nurse should be very kind, courageous, and cheerful. He thinks that the system of most British hospitals is wrong, in that they are understaffed and the nurses overworked, and this of course prejudices the patients' chances of recovery.

The National Baby Welfare Council has published a four-page leaflet dealing with menstruation which has been drawn up by medical experts on the Council's executive committee. The information and advice are given in simple, straightforward language. Copies of this pamphlet (2d. each or 1s. 9d. a dozen) can be obtained from the National Baby Welfare Council, 29, Gordon Square, London, W.C.1.

Preparations and Appliances

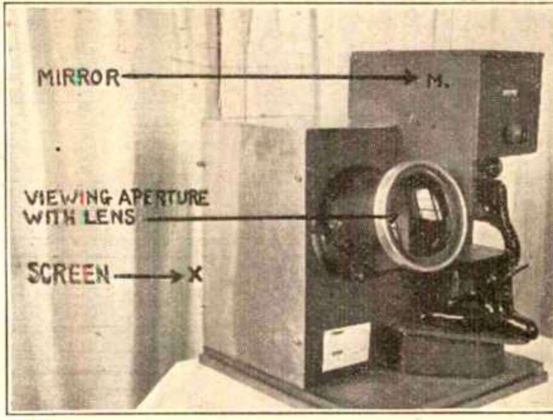
PROJECTION MICROSCOPE FOR USE IN DAYLIGHT

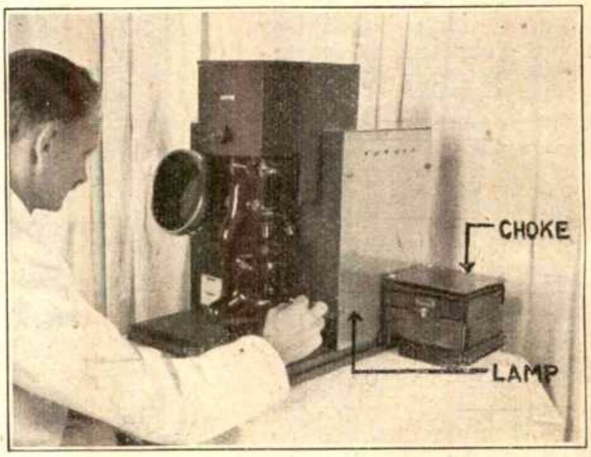
Dr. T. S. DAVIES, Hensol Castle, Pontyclun, Glam., writes:

After visiting a large London hospital recently, and being struck by the great inconvenience caused to the laboratory when it has to be blacked out to do any sort of projection microscopy, I thought that the projection microscope which was constructed locally and at no great cost might be of interest in that it operates in daylight and obviates the necessity for any sort of a dark-room.

The apparatus consists of a box measuring 15 × 14 × 11 in., which is divided into halves by a partition. In the right half is installed a projection lamp, which must be of great intensity and have a small light source. A hole is cut in the box in front of the lamp, and the microscope mirror is placed in front of the hole so that the rays of light are directed upwards through the microscope. On emerging from the eye-piece the light rays strike a mirror (M), which is placed above the eye-piece, and is inclined downwards and to the left, so that an image is thrown on to a screen which is situated at the back of the left-hand compartment of the box. This screen is viewed through a fairly large circular opening, into which is fitted a circular tube, and (to facilitate examination of the screen) a fairly large lens with a long focal length is placed at the examiner's side of the tube. The mirror above the eye-piece is housed in a box-shaped cowling to prevent extraneous light gaining entrance to the screen.

The microscope is not in any way attached to the box, and can be moved therefrom immediately and used in the normal manner. The operator sits in front of the apparatus, as shown, and there is much less fatigue in the use of the microscope thus than when used in the orthodox manner. The most crucial item in the whole apparatus is the projection lamp. After trying many lamps, by far the best has been found to be the new box-type mercury-vapour lamp which combines a small source with one of great intensity and can be run off the mains through a choke supplied with the lamp by the makers (B.T.H. Co., Ltd.).





In the matter of a screen, any simple white flat material—a piece of white paper—is satisfactory. Good resolution is obtained with the 2/3 and 1/6 in. objectives, but not with an oil-immersion 1/12 in. The apparatus has been found very useful for such work as the examination of urinary deposits, blood counts, etc., and greatly lessens the fatigue associated with long periods of microscopical work.

I wish to acknowledge the encouragement given by the medical superintendent, Dr. E. Lewis, with whose permission this article is forwarded.

FLAVAZOLE

"Flavazole" is an equimolecular chemical combination of 2:8-diaminoacridine (proflavine) and sulphathiazole. It has recently been reported (*Lancet*, July 28, 1945, p. 97) to have valuable properties as a wound antiseptic. It is less irritant than proflavine, neutral in reaction in solution, and combines the bacteriostatic powers of its two components; indeed, the action on Gram-negative bacilli, notably *Proteus* and *Ps. pyocyanea*, is apparently enhanced by the combination. It has been used chiefly in powder form, 2 parts being diluted with 98 parts of sulphathiazole. Insufflation of this powder eliminated the infection in a large proportion of wounds awaiting plastic repair and even in pressure sores. Flavazole may be used in the form of saturated solution in any infected cavity and even in the conjunctiva (solubility in water is 1 in 2,500). It is compatible with penicillin, which can therefore be added to flavazole-sulphathiazole powder if necessary.

Flavazole is prepared at Nottingham by Boots Pure Drug Co. Ltd., and is available in bottles of 25 or 100 g.; sterile compound flavazole powder (flavazole 2%, sulphathiazole 98%) can also be obtained in cartons of sifter packets each containing 5 g.

MEDICINE'S DEBT TO PASTEUR

Fifty years ago, on Sept. 28, 1895, Louis Pasteur died in his 73rd year. Though not a medical man he contributed more, both directly and indirectly, to the advance of medical science in the second half of the 19th century than perhaps any other man. The first half had seen the building up of solid knowledge of the correlation between physical signs and morbid anatomy, but of the causes of disease there was, as Osler said, " Before Pasteur, Egyptian darkness." In the retrospect one is struck with the beautifully logical development of his ideas, which grew from a minor point to wider problems. He was impressed by Laplace's vision of " a Galileo or a Newton arising through a series of inductions from particular phenomena to others more far-reaching," and this characterized all his work. Thus, trained as a chemist he turned to crystallography, and (incidentally creating stereo-chemistry) by his studies of dextrorotatory and laevorotatory tartaric acids, showed that only the former underwent fermentation, and that by means of living organisms—a thesis persistently denied by Liebig. When asked what was the use of his more recondite researches, he retorted by repeating Benjamin Franklin's question, " What is the use of a newborn child ? "—a hint which might be taken by those present-day scientists who would restrict scientific research to subjects of " social value."

Pasteur quickly showed the social value of his researches in crystallography by curing the diseases of beet sugar, wines, and beer ; but what authority could have anticipated this ? Moreover he said, " What would be most desirable would be to push these studies far enough to prepare the road for a serious research into the origin of various diseases [such as] putrid and contagious ones," believing, as the far-sighted Robert Boyle had expressed it in the 17th century, that " he who could discover the nature of ferments and fermentation would be more capable than anyone else of explaining the nature of certain diseases." Accordingly Pasteur started the study of silkworm disease, which was devastating the industry in these worms in France, and restored it to prosperity by discovery of the parasite responsible. He was bitterly opposed by the believers in spontaneous generation—a theory which it might have been supposed had been killed by Redi in the 17th century ; but far from it, for this was the root of the opposition to the germ theory of disease. To do his opponents justice, they felt, as Piorry put it, " it is not the disease, an abstract thing, which we have to treat but the patient whom we must study with the utmost care." Their mistake was to deny the germ theory entirely ; if they had not done so they might have realized that Pasteur himself had presented them with a proof that the soil mattered as well as the seed when he showed that animals naturally immune to an infection lost that immunity if placed under unfavourable conditions. Undeterred by opposition Pasteur went on to investigate the epidemics of " splenic fever " which were destroying valuable flocks and herds throughout France. He proved that they were due to infection by anthrax and perpetuated through the action of earthworms bringing to the surface the bacilli and spores from the buried bodies of animals that had died from the disease. His studies of chicken cholera led him to the important discovery of methods of attenuation of viruses and thus to the preparation of vaccines. " Is it not permissible," he said, " to believe by analogy that a day will come when easily applied preventive measures will arrest the ravages " of epidemic diseases ? A dictum of his that " the best proof that an observer is on the right track lies in the uninterrupted fruitfulness of his work " was now to be strikingly illustrated by the application of his principle of attenuation to the treatment of hydrophobia. Early impressions persist, and one of Pasteur's childish recollections was the terror inspired in the Jura by the inroads of a mad wolf. He therefore attacked the problem with great energy and, as is well known, with great success, to which the foundation of the Pasteur Institute in Paris by public subscription was a striking witness. Here, with the assistance of Roux, Yersin, Chamberland, and Metchnikoff, his beneficent work continued and expanded, giving rise to similar institutes in various parts of the world. But there is no institute for hydrophobia in Great Britain, for the muzzling order stamped out the disease here. Pasteur's last years were rejoiced by the discovery of diphtheria antitoxin by Roux and Yersin at the Institute, and shortly after by Yersin's discovery of the plague bacillus in India. But perhaps his greatest pride in his followers was for Lister, whose earlier adaptation of Pasteurian methods to the control of sepsis after operation is recognized throughout the world as one of the greatest boons to suffering humanity—a striking instance of the fruitfulness of a single idea faithfully pursued.

Pasteur's work, here rapidly sketched, was the measure of the man, patient and indefatigable, remorseless in his criticism of his own findings, single-minded in pursuit of truth, and devoted to the welfare of mankind and therefore a firm believer in the internationalization of science. No man can have met with fiercer or more bitter opposition than this great benefactor. It is to be regretted that he spent so much time confuting adversaries who had only the flimsiest evidence to support them ; but for one of his temperament it was impossible to leave the battlefield against ignorance just as it was impossible to deny pity and help to real suffering. A hard hitter in controversy, he had also a gift for loyal and devoted friendship. Perhaps his creed was best expressed in words from his oration at the opening of the Pasteur Institute—words which are even more relevant to-day than when they were spoken : " Two contrary laws seem to be wrestling with each other nowadays : the one of blood and death, ever imagining new means of destruction and forcing nations to be constantly ready for the battlefield ; the other a law of peace, work, and health, ever evolving new means of delivering man from the scourges which beset him. . . . The latter places one human life above any victory, while the former would sacrifice hundreds and thousands of lives to the ambition of one. . . . Which of these two laws will ultimately prevail God alone knows."

FENESTRATION FOR OTOSCLEROSIS

Fenestration as a mode of relieving the deafness of otosclerosis has passed the experimental stage and has come to stay, though so far it has not been much practised in Great Britain; a technique which promises to give 80% of good results deserves close attention. The operation has now passed from the period when it was done in multiple stages, but it is long and tedious; the opening into the labyrinth must be made under magnification, with fine burrs, and it must remain in the hands of a few with special aptitude. The operation does not cure the disease, but it is the only means available, apart from hearing aids, of relieving the deafness. There is some evidence that the decompression may halt the progress of the disease, as it has been noticed that in cases of successful unilateral operation on the worse ear the hearing in the previously better ear has continued to deteriorate. During the past year or so the operation has had a good deal of publicity, and many inquiries about it have been sent to the *Journal*. A full review of the subject would therefore seem to be opportune.

The clinical conception of otosclerosis is not necessarily quite identical with the pathological, as the diagnosis must ordinarily be made from clinical signs and symptoms, which only on rare occasions can be checked by pathological examination, though much histological study has been carried out, notably by Albert Gray[1] and Felix Nager.[2] Clinically the principal symptom is progressive deafness of conduction type, generally with tinnitus, in an adolescent or young adult with normal tympanic membranes and unobstructed Eustachian tubes. This deafness turns occasionally in advanced cases into a total loss of hearing from perception deafness. In about half the cases there is a familial or hereditary history of deafness, which also in about half the cases begins between the ages of 16 and 30. Pregnancy and childbirth are known to aggravate the deafness sometimes, though Nager thinks that the influence of these factors has been overestimated. A symptom of this kind of deafness is the ability to hear better in a noise—the paracusis of Willis—which occurs in about one-fifth of the cases. Gray has explained how this is produced by the superimposition of one series of vibrations upon another of much greater amplitude, the vibrations of smaller amplitude acting when the system is passing through the position of equilibrium for the vibrations of greater amplitude. As this effect can be produced only by a partial fixation of the stapes, the symptom is of bad omen in prognosis. This fixation of the stapes has been found to be the essential physical factor in the deafness, and histological examination has shown that the ankylosis is only a part of a profound change which takes place in the temporal bone. This change begins with a continuous lacunar resorption in the bony capsule of the labyrinth, shown by finger-like processes of bluish tissue (so-called blue mantle) which have each a small blood-vessel in the centre. These blue mantles represent the first change—a condition of which the aetiology is unknown. The mantles turn into areas of dark-staining porous bone with large marrow-filled spaces and a good line of demarcation, shown by deep staining with haematoxylin and eosin. These changes often arise in mute regions, but the points of predilection are the angle in the outer wall of bony labyrinth between the cochlea and the vestibule, the round window, and the bone surrounding the internal auditory meatus. The extent of the pathological changes therefore bears no necessary relation to the severity of the deafness, which depends on the effect on the stapedio-vestibular ligament, on the frames of the windows, which may be closed by exostoses, and on the auditory nerves. No evidence of any general metabolic disorder of bone has been found, though Gray noted that many patients, of whom 8 out of 9 are females, are anaemic, and no treatment is known which will arrest, and still less reverse, the pathological changes.

A similar though not identical localized osteodystrophy has been observed in Paget's and in von Recklinghausen's diseases. It will be appreciated, therefore, that the clinical and pathological aspects do not precisely correspond, since the stapes may become fixed in the oval window by some other adhesive process and cause obstructive deafness. Attempts to relieve the deafness and tinnitus by extraction of the stapes have always failed, but it has been known for about thirty years that, if an opening be made into the lateral semicircular canal without damage to the membranous labyrinth, this decompression improves the hearing for about ten days, but it returns to the previous state in six or eight weeks, when the opening has closed. Much time and ingenuity have therefore been expended upon attempts to make an opening which will not close. Holmgren[3] in particular has been a tireless worker in his endeavours to achieve this. Thiersch grafts, fat grafts, mucoperiosteum, gold leaf, laminaria, rubber, platinum wire, have all been tried, as well as electrolysis and irradiation, as means of keeping the fistula patent. This has led eventually to the accepted plan of placing the fistula far forwards—so far forwards that Lempert claims it is actually in the dome of the vestibule—and covering the opening with a flap formed from Shrapnell's membrane and the adjacent skin of the external meatus. Shrapnell's membrane can be displaced for this purpose by removing the incus and excising the head of the malleus. As an example of the results claimed for this kind of technique, by which the so-called fenestra nov-ovalis is covered with a flap, Shambaugh[4] states that 182 out of 201 cases—that is, 90%—have improved hearing for more than one year, and in 33% the gain was more than 30 decibels. The most suitable subjects for fenestration, however, are just those most helped by a hearing aid, and this often amounts to over 40 decibels, so that a properly fitted hearing aid often gives greater amplification than the corresponding improvement by fenestration. The improvement obtained by fenestration, however, is not subject to the disadvantages of hearing aids, which amplify extraneous disturbing sounds and are a poor substitute for normal hearing. Further, the power of hearing for speech rather than for the sounds produced by a pure audiometer is the crucial test, so that the tests should be made by a speech audiometer rather than recorded in decibels for pure tones. An audiometric improvement of 10 decibels in a very deaf patient is of no value if it does not enable speech to be heard. Taking such points into consideration, Shambaugh claims for fenestration a 90% chance of lasting improvement, and a 70% chance that this improvement will equal or surpass that obtained by a hearing aid.

[1] *Loose Leaf Medicine of the Ear*, 1939, p. 259, T. Nelson and Sons, New York and Edinburgh.

[2] *Diseases of the Ear*, 1910, p. 97, Baillière, Tindall and Cox, London.

[3] *Loose Leaf Surgery of the Ear*, p. 399, T. Nelson and Sons, New York and Edinburgh.

[4] *Arch. Otolaryng.*, Chicago, 1945, 41, 189.

It may be accepted that rather less than half (probably about one-third) of the patients treated by this technique have gained real benefit. An improvement which is revealed only by a number of decibels on an audiogram does not justify a claim to success, for the improvement must be great enough to bring the hearing within the conversational range. Unless this is achieved the operation is clinically a failure, so that an exact percentage of successful results, where the crucial test is subjective, is not easy to estimate. Lempert,[5] however, observed that, even when the new window was kept open and the fistula test for nystagmus remained positive, success was not assured, and that in a number of cases which appeared to be successful technically the improvement disappeared. A post-operative non-suppurative labyrinthitis was usually regarded as a tiresome complication, but Lempert concluded that on this account, although the hearing at first becomes better, it worsens after two or three days and does not improve again until two or three weeks have passed. There is then a rapid improvement corresponding to that which immediately follows the operation. The drop in hearing is due to a non-suppurative labyrinthitis, and the hearing does not remain better until this post-operative labyrinthitis has subsided; but it may cause permanent changes which would account for the failures in which the hearing does not return to the immediate post-operative level. Lempert found that this post-operative labyrinthitis occurred in nearly every case treated by this technique, and that if uniform results were to be obtained some means of eliminating it would have to be found, as the cases which preserved the improvement, without a drop followed by a secondary improvement, were very few.

The source of this post-operative labyrinthitis is presumably the flap of tympanic membrane and meatal skin which covers the new window and lies in contact with the perilymphatic space, so that an inflammatory extension to the membranous labyrinth could easily take place. Covering the opening with a slice of cartilage lying between the flap and the perilymphatic space was not found to be any protection against labyrinthitis; to obtain this the cartilage has to be shaped into a disk, which fits and closes the opening. As Lempert claims that in this way the improved hearing is retained and the post-operative labyrinthitis is avoided, it appears that it is not necessary to keep the fistula open and covered only with a thin membrane, but that it may be closed with what Lempert describes as a "mobile stopple" of cartilage, which is a substitute for the footplate of the stapes, from which indeed it is separated only by the facial nerve.

It is not possible to follow in detail here the numerous steps which led to the evolution of this new technique, but Lempert[6] now states that out of 10 cases in which the new window was made and filled with a disk of cartilage which on the one hand extends half a millimetre beyond the inner or endosteal surface of the bony rim into the perilymphatic space, and on the other protrudes the same distance outwards beyond the bony rim of the new window into the epitympanum, 8 retained the improvement in hearing without interruption by labyrinthitis. It seemed that in the other 2 the stopple did not retain its mobility, for the hearing returned to the pre-operative level. Since the stopple is squeezed into the opening like a cork it is difficult to understand how it retains the necessary mobility, and this point requires further elucidation, as it is hard to imagine that any structure comparable to the stapedio-vestibular joint with its annular ligament can be organized in this way.

AN EXPERIMENTAL STUDY OF A MAN AND HIS STOMACH

The second printing of *Human Gastric Function* by Wolf and Wolff[7] will gain a wider audience for a book which has already become a modern classic of medical literature. It is the report of a series of studies on a patient with a large and prolapsed gastrostomy through which the responses of the stomach could be intimately observed. A book of this kind naturally invites comparison with Beaumont's account of Alexis St. Martin, and we are again reminded how inspired and accurate Beaumont's work was. Nevertheless, changes occur in men's outlook. Beaumont was largely concerned with the mechanism of gastric secretion, and Carlson, in a similar case and at a later date, with gastric motility, whereas Wolf and Wolff have been most interested in the effects of emotion on the stomach. The physiological data which they have collected are also of much value. The gastric mucosa varies in colour from a faint yellowish pink to an intense cardinal red, or approximately the whole range of the Tallqvist haemoglobin scale. During the resting stage the stomach is pale and quiet, and acid is secreted in small amount. Colour, rate of secretion, and motor activity generally run parallel, and all increase in preparation for eating at the mention of appetizing food. The layer of mucus on the surface of the stomach is of immense importance in affording protection from the corrosive action of the gastric juice. The normal gastric mucosa does not respond to irritation or stimulation with pain; the only pains which can be induced are the pain of heartburn, which is due to irritation of the lower end of the oesophagus by acid juice or similar stimuli, and the pain of distension or strong contraction of the musculature. When, however, the mucosa is congested and inflamed, intense pain occurs on the application of the usual stimuli, and engorgement also lowers the threshold for muscle pain. The response of the stomach to drugs and other stimuli is much affected by the emotional situation, and the analysis of the effects of emotion forms the main theme of the book.

[6] *Arch. Otolaryng.*, Chicago, 1945, **41**, 17.

[7] *Human Gastric Function*, Oxford University Press (New York), 1943 (second printing 1944). English price, 25s.

It is evident that the psyche of Wolf and Wolff's patient had been affected by his gastrostomy, which had been performed in childhood for a stricture of the oesophagus following a scald. It had given rise to a sense of insecurity and the fear of being humiliated, and had undoubtedly impaired his capacity to show or to respond to affection. He used to chew his food first and then put it into his gastrostomy, a procedure which caused him considerable embarrassment, and his world was divided into those with whom he could eat and those with whom he could not eat. With the former he was frank and intimate, but with the latter often detached and suspicious. His family training and his disability had combined to make him set up ideals which he was not always able to sustain in practice. For all these reasons he often suffered severe and protracted emotional disturbances which made him an ideal subject for the study of the effect of the emotions on the stomach. Sadness, discouragement, and self-reproach were associated with prolonged pallor of the gastric mucosa, hyposecretion, and hypomotility; anorexia and slight nausea were observed in these circumstances. With resentment and hostility the mucous membrane was turgid, engorged, and redder than usual, the gastric secretion was much increased, and vigorous contraction occurred. Prolonged anxiety and emotional tension were accompanied by sustained hyperfunction of the stomach which persisted during sleep. In these periods of anxiety appetite was often greatly reduced, showing that the physiological state of the stomach does not determine the presence or absence of appetite. The phenomena are comparable with data from patients with peptic ulcer, showing that symptoms are prominent during times of emotional conflict. The appearance of the hyperfunctioning stomach is identical with that of gastritis. The folds are thick, red, and succulent, and the slightest trauma or even vigorous contraction of the stomach results in the appearance of red haemorrhagic spots or erosions. If hypersecretion continues, and the mucous protection of the surface is diminished, erosions may develop into chronic ulcers. An inflamed area is in itself an adequate stimulus for hypersecretion.

The observations of Wolf and Wolff go a long way to show how mental impressions and feelings might lead to hypersecretion and chronic ulceration of the stomach or duodenum, though it must be noted that their patient had no ulceration within the stomach and that an ulcer was produced only in the prolapsed mucosa where the protective coat of mucus was reduced. Their book has wider implications also. Psychosomatic medicine is at present passing through a phase of uncritical enthusiasm, just as analytical psychology did a generation ago. There is the same tendency to unbridled speculation, to the interpretation of natural phenomena *ex hypothesi*, and to a rather primitive and pictorial type of thinking. The history of science records how often men have gone astray because they have not checked their hypotheses by controlled observation and experiment, and Wolf and Wolff's technique should be a pattern for workers in this field.

MODE OF ACTION OF VITAMIN D

Radio-active "tracer" or "tagged" elements have been used to study the metabolism of a number of elements, including iron, calcium, iodine, and phosphorus. The technique consists of making a radio-active isotope of the element by bombarding it with deuterons in a cyclotron and, after ingestion or injection, by following the course of the radio-active or "tagged" element through the body by means of a Geiger-Müller counter. This picks up the radiations emitted by the radio-active isotopes and serves for their detection and estimation. With this technique Cohn and Greenberg[1] [2] have studied the mode of action of vitamin D in rickets. It has been widely accepted that vitamin D acts by increasing the absorption of calcium from the gut and the urinary excretion of phosphorus, but that it has no effect on either the faecal excretion or the absorption of phosphorus. Many workers have felt this explanation to be inadequate, and believe that, apart from its action on the absorption and excretion of calcium and phosphorus, vitamin D has a direct influence on the mineralization of bone. Using radio-active phosphorus, Cohn and Greenberg[1] showed some years ago that vitamin D aids the conversion of organic to inorganic phosphorus in bone. Cohn[2] has now investigated the action of vitamin D in rickets by giving rachitic rats irradiated ergosterol and radio-active calcium by intraperitoneal injection or stomach tube. Three days later the animals were killed and the radio-active calcium estimated in the excreta, bones, teeth, and carcass. The excreta and the skeleton were found to contain the bulk of the radio-active calcium, the amount in the soft tissues being comparatively negligible. These observations confirmed the view that vitamin D promotes the absorption of calcium from the digestive tract, and also proved that it exerts a direct effect on the mineralization of bone in rachitic animals.

CANINE HYSTERIA

Canine hysteria—also known to veterinary surgeons as running fits, fright disease, epizootic hysteria, and infectious hysteria—is an ill-defined disease of dogs, the aetiology and treatment of which have long been in dispute. The symptoms associated with it are paroxysmal attacks of hyperexcitability, manifested by running, barking, or howling, defective vision and balance, dementia, and sometimes clonic convulsions, during which a heavy mucous saliva is secreted and the animal frequently urinates and defaecates. The affected dogs appear to be indifferent to pain or to attempts to calm them. It is thought that excitement, physical strain, and sudden stimuli, such as a sudden noise or flash of light, may precipitate attacks. Heredity has also been thought to be a causal factor. Many authorities believe the disease to be related to defective nutrition. Lack of vitamins A and B_1, of magnesium, and of lysine have been suggested as causes, and also a toxic factor or factors in wheat products.

Wagner and Elvehjem[3] have recently brought forward evidence to show that canine hysteria is dietary in origin. The terms "epizootic" and "infectious" to qualify the disease are ill chosen, as there is little evidence that an infectious agent is responsible. Well-fed animals kept alongside affected animals showed no signs of the disease. Wagner and Elvehjem produced the disease in dogs by feeding them on baked dog foods containing wheat gluten flour and on experimental rations containing the same material. Although the proteins in gluten are deficient in lysine, protein and lysine supplements did not prevent the onset of the disease. The fact that hysteria was caused by feeding wheat gluten flour to dogs receiving nutritionally adequate rations suggested there was some toxic factor in the flour, or possibly a deficiency of an essential food factor. It is possible that if the effect of the toxin were not too severe, correction of the deficient food factor might increase the animals' resistance to the supposed toxin. This might explain the curative effects reported in the past of supplements of casein, lysine, vitamin A, and vitamin B_1.

LONGEVITY AND OLD AGE IN THE PUNJAB

BY

Khan Bahadur M. YACOB, M.B., B.S., D.P.H., D.T.M.&H.
Assistant Director of Public Health, Punjab

AND

SATYA SWAROOP, M.A.
Statistical Officer, Public Health Department, Punjab

(ABRIDGED)

To the medical profession hitherto the problem of old age has presented its chief interest in connexion with the methods of prolonging human life, such as Voronoff's technique of grafting slices of simian testes in the testes of man, Steinach's advocacy of vasectomy, and the use of testicular and ovarian extracts. From the eugenic, social, ecological, and other points of view, however, the question of longevity raises some serious and complex problems. For example, after a certain age, when man's productive capacity dwindles, he becomes a dependant and remains so until death. India is already supporting a large number of dependants—invalids, beggars, widows, and others—and might well ask whether an attempt to prolong human life and thus increase the proportion of the aged would not add to the heavy burden of her poor working population. In a leading article in the *British Medical Journal*[1] some interesting comments were made on ageing and the care of the aged, and the White Paper on Social Insurance was quoted to the effect that in Great Britain between 1965 and 1975 there will be an increase of about 800,000 in the pensioner population and a decrease of more than one million in the contributing population, supposing the present decline in the birth and death rates to continue. In India the question of pensioners is not yet important, but that of dependancy is present in many forms.

The Limit of Human Life

The limit given by the Psalmist to human life is often much exceeded both in the East and in the West. In India the Vedas [Brahman sacred writings] enjoined men to live 100 years, and this age is known to have been reached fairly often in the Punjab as well as elsewhere. There has been some speculation in scientific literature about the ideal duration of life. Rolleston[2] quotes Hufeland as laying down the law that animals generally live about eight times as long as they take to reach maturity, and Hufeland's figure of 200 years as the ideal span of life is obtained by regarding 25 as the termination of adolescence. Both figures—8 and 25—appear to be arbitrary. Flourens calculated that, throughout the animal kingdom, life was five times as long as the period taken to complete growth, as marked by the union of the epiphyses of the long bones, and as this union took place at 20 or 21 the the span of human life should be about 100.

It is of interest to recall some extreme claims for longevity, admitting, of course, a considerable lack of accuracy in age records. Rolleston[2] quotes the cases, among others, of Henry Jenkins, who lived from 1501 to 1670; Thomas Parr, who lived from 1483 to 1635; and Katherine, Countess of Desmond, who lived 145 years, though some have said that the ages of two Countesses of Desmond were telescoped into one. The question of the longest life to be reasonably attested is of interest to actuaries, and in an American actuarial publication Dublin and Lotka[3] cite the case of C. J. Drakenberg, a Danish seafarer, who was born in 1626 and died in 1772. It is declared that he was sturdy and robust and temperamentally very impetuous. At the age of 111 he married a 60-year-old widow, who died a few years later, and at the age of 130 he proposed to several women but without success.

In India an interesting case was recorded in the 1931 census report[4] of one Siddi Wastad, the son of a negro father and Arab mother, who lived in Nagpur. At the time of the census he was supposed to have passed his 150th year, but the census superintendent for the Central Provinces stated that, even allowing for much exaggeration, his age would then have been 130 years. We addressed an inquiry to Dr. R. L. Tuli, Director of Public Health, Central Provinces, who has informed us that Siddi Wastad died at the age of 158 years on August 14, 1943. He was a famous wrestler at the court of the Maharajah of Baroda. Until the influenza epidemic of 1918 he remained in perfect health, but he was attacked by that scourge and gradually lost his teeth and his hair turned white. Until then it had not been his habit to lie down or go to bed. A short nap in a chair at night was all that he needed, and he offered his prayers five times a day. His diet up to that time was six pounds of flour for one meal, as well as vegetables, rice, mutton, and four seers[5] of milk each day. When ill he never took drugs, but he prepared his own medicines and medicated oils and treated himself.

Outstanding Age Records in the Punjab

We sent a request to all the district and municipal medical officers of health in the Punjab for recent information concerning long-lived persons in the Province, and some very interesting replies have been received, enabling us to state that this Province has a good number of persons who have passed the century. We further requested the officers to throw light on the state of health enjoyed by persons who had lived to advanced ages. It is not possible to comment in detail on the information supplied; in some cases further inquiry seemed necessary. Only a few salient points may be briefly mentioned.

The maximum age so far reported to us as having been reached in recent times in the Punjab is 138 years. This was the age of a person named Khan Dadan Khan, who died of fever four years ago in the Rawalpindi district, a hilly part of the Province. The death also occurred last year of Khanam Jee, in Rawalpindi city, at the age of 135 years. Two more deaths each at the age of 130 years have been reported from Lahore and Lyallpur districts. An interesting account has been received of one Saleh Mohammed Khokhar, who died recently at the age of 120 years in the Rawalpindi district. The district medical officer of health reports of this man that his grey hair had grown black and that new teeth had appeared. He was accustomed to eat maize, meat, and leafy vegetables, and he never drank tea. Quite a number of other instances have been reported to us of persons who have died recently at the ages of 110 and 130. Generally the cause of death has been stated to be "fever" or "old age," both vague terms. Without further inquiry nothing can be stated as to the precise cause, though we have little reason to doubt that malaria has been an important one.

Among the living in the Punjab a person is reported to have reached 130 years of age in Sialkot, 70 miles from Lahore. His state of health is said to be good. A dhobi [low-caste Hindu] 125 years of age is reported to be living in Amritsar. He attributes his longevity to his habit of taking the gum of the pipal tree [the sacred fig]. Two women of 120 years are reported —one in Ambala, near Simla, in a satisfactory state of health, and the other in a village in the Gujrat district, who is blind, deaf, and bedridden. The number of persons who claim to be over 100 years of age is fairly large. Most of these living persons claim that their longevity is due to the inclusion of ghee [clarified butter], milk, and dairy products in their diet. Some have been taking a few seers of *lassi* daily during both summer and winter. Abstention from tea and tobacco, moderation in sexual life, and plenty of exercise when young are some of the other factors which these persons claim to have contributed to their longevity. Among the diseases from which they suffer in their old age malaria, eye troubles, bronchitis, and pneumonia are mentioned, but these, of course, are just those affections which constitute the recognized general causes of ill-health in the Punjab.

Expectation of Life in the Punjab

[The authors then turn from the discussion of a few cases of exceptional longevity to the length of life of the population of the Province as a whole, and they explain what is meant by the phrase "expectation of life" as used in census returns and by insurance corporations. The estimate is made by actuaries for each age and shows, on the average, the added number of years for which people of that age are likely to survive. They state that there are some objections to the use of expectation-of-life figures relating to India for making long-term comparisons, but for the immediate purpose of studying longevity in the Punjab such estimates may be regarded as fairly useful.]

The latest estimates of expectation of life in the Punjab, as in the rest of India, followed the census enumeration of 1931.

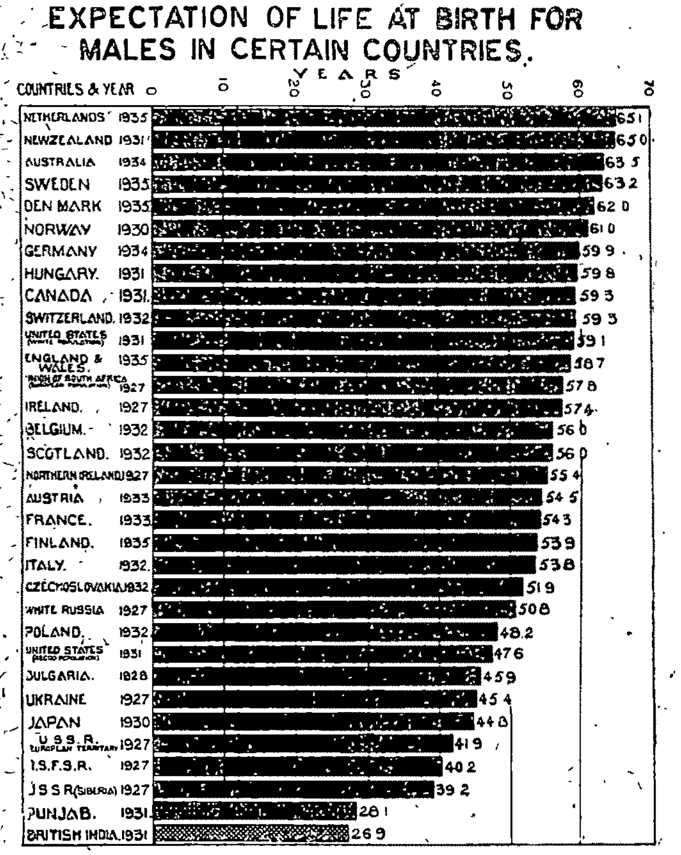

CHART I

The war has stood in the way of obtaining more resent estimates. We have obtained figures for a number of countries corresponding to the 1931 estimates for the Punjab and for British India, and these are presented in Chart I, the countries being arranged in decreasing order of expectation of life at birth for the male inhabitants. The Netherlands are at the head of the list with as high an expectation of life as 65.1 years, and New Zealand and Australia rank next. British India is lowest in the chart, with 26.9 years, and the Punjab is only slightly higher (28.1). Generally speaking, all the advanced countries of the world, especially those in the West, have an expectation of life far in excess of the Punjab and British India. Among Eastern countries, the figure for Japan (44.8) is interesting; it is more than one and a half times the British India figure.

Within India itself the Provinces show variability, though not as large as that seen in the comparison of countries. Chart II gives the figures for the Provinces, and for males and females in each Province. The Provinces are here arranged according to an increasing expectation of life for females. The highest estimates are for Madras, where the females show a figure of 30.04 years (the only instance in which 30 years is reached). The lowest estimates are for the area adjoining Bengal, comprising the North-West Frontier Province, Sind, and Baluchistan. The Punjab figures are exceeded by those of Bihar and Orissa, the Central Provinces, Berar, and Hyderabad, and Madras.

Lower Female Longevity

It is almost a universal experience that females are longer-lived than males, but the Punjab affords a striking exception, as also do the North-West Frontier Province, Sind, and Baluchistan, Bombay Presidency, and Bihar and Orissa. Probably the lack of adequate facilities for maternal relief and care, coupled also perhaps with a rather unfavourable attitude towards the weaker sex in the Punjab, are responsible for keeping female longevity at so low a level. In making the statement about an unfavourable attitude towards females we are supported by the great amount of evidence pointing to the practice of female infanticide in this Province in the past.

The attention of the British Government was directed to this subject immediately after the annexation [1849]. Lord Lawrence, while Commissioner of Trans-Sutlej States, promulgated three commandments, the second of which was, "Thou shalt not kill thy daughter." But writing in 1895 Sir James Douie recorded that "fifty years after Lawrence denounced the murder of female infants we are still discussing the best method of putting down that inhuman practice." Several causes tended gradually to restrict the extent of female infanticide, but while in recent years the killing of female infants may have altogether disappeared, the social customs and mental traits which found expression in such inhuman action may still exist among certain classes, with the result that females generally may lead a more neglected life than males.

A low expectation of life for females, which implies a higher mortality rate among them, affects indirectly the male population, because a large number of women die as the result of pregnancy and childbirth, which involves the potential loss of male as well as female children.

In order to illustrate the point that lack of maternity facilities, together with, perhaps, a general neglect of the female population, has brought about reduced longevity for females in the Punjab as compared with males, we quote the mortality statistics for the sexes at different age periods. The figures set out in Table I are based on the average experience of the quinquennium 1935–9, and the death rates are given per 1,000 of the corresponding populations (except that in the first age group the mortality rates have been calculated per 1,000 live births).

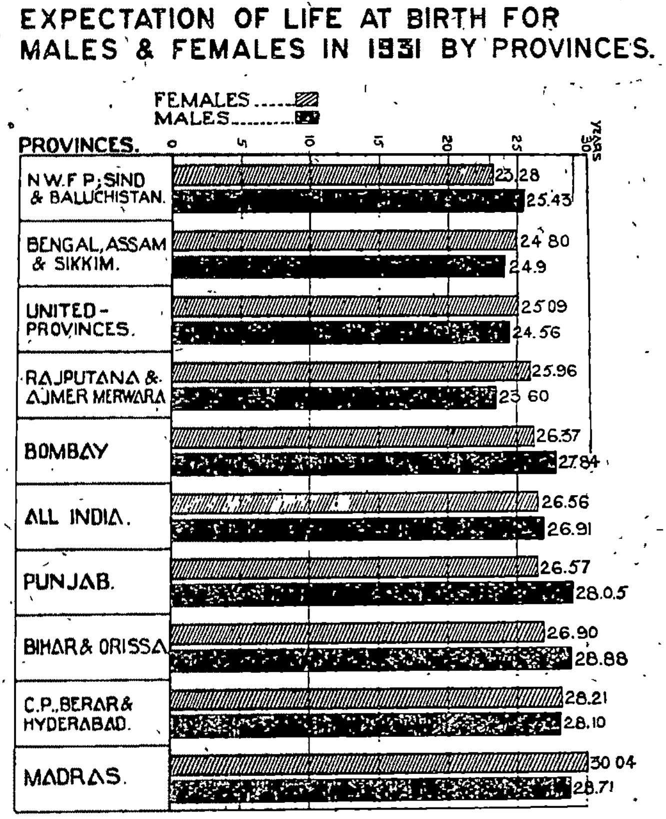

CHART II

Female infants show a lower mortality than male infants; this is also true of the next age group. But from the age group 10–15 years onwards the female population must be considered to have started the reproductive span of life, and they are found subjected to adverse mortality rates. The difference persists throughout the reproductive period—namely, up to about 40 years. In the ensuing two age groups the difference between male and female mortality rates becomes less, though the females still have the higher rate, and beyond 60 the difference again increases, to the disadvantage of the female population. On the whole, therefore, this table presents the picture of a female population born stronger than the male, but subjected during the prime of life to adverse circumstances, and continuing to live thereafter the life of a weaker sex, in the real sense of the word.

TABLE I.—*Death Rates per 1,000*

Age Group	Males	Females
Under 1 year	172	157
1–5 years	37	34
5–10 "	9	9
10–15 "	7	8
15–20 "	8	10
20–30 "	7	9
30–40 "	9	11
40–50 "	14	15
50–60 "	24	25
60 and upwards	61	64

Further Deductions from Tables of Mortality

Mr. L. S. Vaidyanathan, the actuary appointed by the Government of India at the 1931 census, studied the same point—namely, the comparative mortality figures for each year of age.[6] He did not believe that the recorded births and deaths afforded reliable information concerning mortality conditions in the population, and he proceeded to calculate mortality rates by making use of the indirect evidence available in the 1921 and 1931 census enumerations only. He found that the females started life with a relatively low mortality rate, and maintained this advantage for a few years. Thereafter the female mortality reached a higher level than the male, and this relative disadvantage continued until about the age of 50. After that; according to Mr. Vaidyanathan's calculations, the females scored over the males again and showed low mortality experience almost to the end of life.

Our own deductions from the recorded deaths in the Punjab agree in the main with Mr. Vaidyanathan's differently derived deductions with respect to women in the prime of life. We differ from him concerning the relative position of the male and female at advanced ages. The census enumeration figures of 1921 and 1931, from which he sought to deduce death rates by age and sex, were by no means entirely reliable. We are therefore unable to decide which estimate is subject to the greater error and which must accordingly be preferred.

Mr. Vaidyanathan is an eminent Indian actuary, and in this discussion of longevity and old age we would quote further from his figures. In Table II are set out the figures for the expectation of life for each decennium from 50 to 90 years. They are shown separately for males and females for the Punjab, for the whole of India, and for England and Wales, and they relate to the year 1931.

TABLE II.—*Comparative Expectation of Life at Decennial Ages*

Age	Males			Females		
	Punjab	India	England	Punjab	India	England
50	15·09	14·31	21·36	16·14	14·65	23·69
60	10·22	10·25	14·36	11·48	10·81	16·22
70	5·98	6·23	8·75	7·03	6·74	9·95
80	2·91	3·13	4·93	3·43	3·25	5·56
90	1·19	1·12	2·82	1·31	1·18	3·13

The table affords many interesting comparisons. At the higher ages, in India as well as in England, females enjoy a longer expectation of life. The reason usually given for this generally favourable position of older women is the fact that they have already passed the dangerous period of their reproductive life. From a biological point of view here is the evidence that, once the period of excessive maternal mortality is over, women again present a picture of a more favourable make-up for survival. This argument also points the necessity for making maternity in the Punjab as easy and risk-free a process as is practicable.

While in England the rate of maternal mortality is as low as 2 or 3 for 1,000 births, in the Punjab it is generally believed to be from eight to ten times this figure.

Survival at Late Ages

Another point revealed by a study of Table II is that, although the figures showing the expectation of life at the higher ages are greater in England than in the Punjab, the difference is not as great as that between the figures for the two countries for the expectation of life at birth. Once, therefore, a person in the Punjab has reached an advanced age, he finds himself in a somewhat more favourable position, and may look forward to living to that greater age which his contemporaries reach in the more advanced countries of the world. At the age of 60, for instance, a male in the Punjab can on the average expect to live another ten years, while a similar expectation in England is about 14 years. Females at the age of 60 in the Punjab may hope to live another 11 years, and in England another 16 years. At the advanced ages females in the Punjab enjoy a longer expectation of life than the average for all India, but Punjabi males show no such appreciable advantage. In fact, at the ages 60, 70, and 80 the expectation of life for males in the Punjab is somewhat lower than that for males in India as a whole.

The smallest area within India for which separate figures for the expectation of life have been worked out is the province; but in order to study the variations existing within the Punjab itself we have calculated the proportion of persons above 60 years of age in the different districts to the total population. The highest proportion of old persons to the total population is to be found in the hilly or sub-montane tracts of eastern and northern Punjab. In fact, four fairly well marked regions are seen as we proceed south and south-west. The lowest proportion is found in the dry and hot districts of the extreme south-east and south-west of the Province—Karnal and Rhotak on the one side and Muzaffargarh on the other. In a general way this geographical pattern lends support to the view that a cooler climate is conducive to the preservation of life. For example, Kangra, a district of 10,000 square miles in the north-east of the Province, although it has a relatively higher number of old people, is not a satisfactory area from the public health and nutritional points of view. The incidence of tuberculosis, pneumonia, dysentery, and diarrhoea is comparatively high, and goitre, rickets, and osteomalacia are peculiar to this area. Yet in spite of such unfavourable circumstances the population includes a higher proportion of older people, and we are led to the conclusion either that the population statistics are entirely unreliable or that the colder climate is a governing factor in this relative longevity.

Changes in Mortality Conditions

When is a person old? In other words, what age should we choose for a study of mortality conditions of old persons in the Punjab and the manner in which these have changed during, let us say, the present century? It is generally believed that when the period of reproduction wanes that of old age begins. In women this is marked by the menopause; in men the onset of senescence may occur at considerably varying periods and be so stealthy as to be undetected by the individual. A philosopher has said that the information that he is old may be suddenly conveyed to a person on overhearing the chance remarks of others, by catching the reflection of his bent back in a mirror, or by finding some girl offering him her seat in an omnibus. But statisticians and biologists have given ages ranging from 45 to 60 as indicating the onset of old age in man.

Vital statistics for the Punjab give mortality figures for ages over 60 in only one group. All we can study, therefore, is the group of persons aged 60 and above in a single combined estimate. The deaths occurring during each year from 1901 onwards in males and females over 60 have been made into rates per 1,000 of population in that particular sex group and are shown in Chart III for each year. The dotted curve is for the females and the continuous line for the males. In spite of considerable fluctuations occasioned by epidemics of plague, cholera, malaria, and influenza, the general indication is that from 1900 onwards the mortality rate among old male and female populations have been on the decrease. Separate trend lines have been fitted by the method of least squares to the mortality experience of the sexes over the entire period of 41 years (1900–40), and these are shown on the chart. Both these lines are sloping downwards, which is an indication of a general improvement in the health conditions of the old. The significance of this decline has been tested statistically, and it has been found that chance alone cannot explain such a marked downward tendency.

---

[6] Vaidyanathan, L. S., Actuarial Report annexed to Census of India, 1932, Vol. I.

TRENDS OF DEATH RATES AMONG MALES & FEMALES OVER 60 YEARS OF AGE IN THE PUNJAB FROM 1900 ONWARDS.

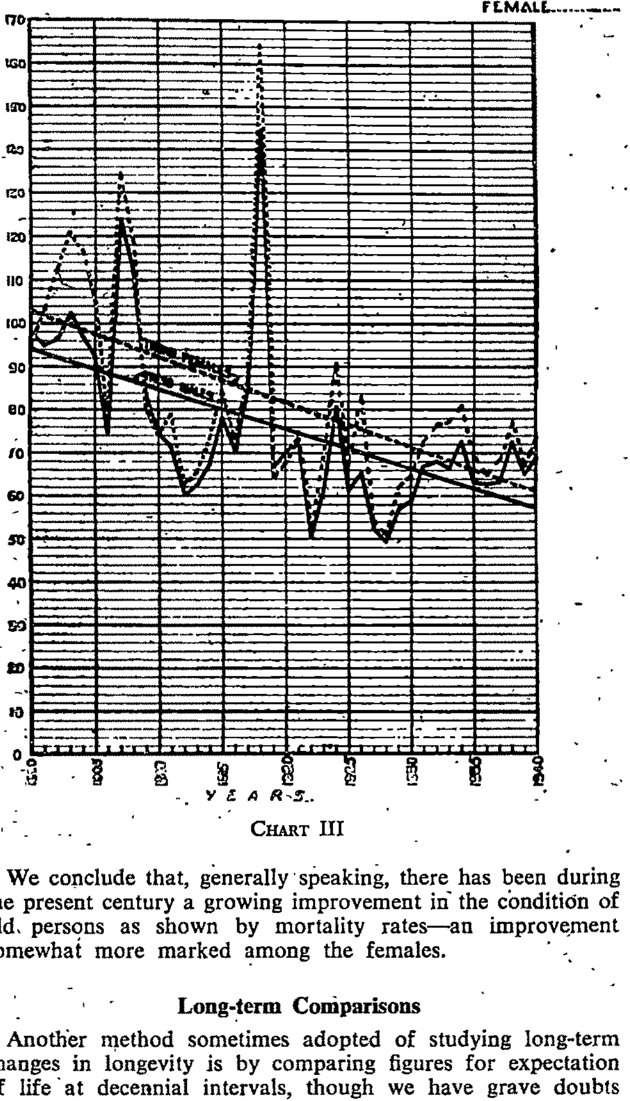

Chart III

We conclude that, generally speaking, there has been during the present century a growing improvement in the condition of old persons as shown by mortality rates—an improvement somewhat more marked among the females.

Long-term Comparisons

Another method sometimes adopted of studying long-term changes in longevity is by comparing figures for expectation of life at decennial intervals, though we have grave doubts whether the Punjab or, for the matter of that, the all-India figures can be quoted with the same degree of confidence as the figures for Western countries.

Table III.—*Expectation of Life in Years for Males at Ten-yearly Age Intervals from 1881 to 1931*

Age	1881	1891	1901	1911	1931
0	25	27	23	21	28
10	36	38	35	31	38
20	30	32	30	26	31
30	25	27	25	22	25
40	20	20	20	18	20
50	15	16	15	14	15
60	10	11	11	11	10
70	6	8	6	7	6
80	3	5	3	3	3
90	1	2	1	1	1

Several factors tend to detract from the value of these figures for long-term comparisons. (1) The figures for 1921 are missing, as the actuary did not consider that they would be of any use. At that time the population had not fully recovered from the effects of the great influenza pandemic of 1918. (2) The estimates after each census were made by different actuaries who used varying methods of estimation. (3) The areas for which the estimates have been made have not always been the same. In 1931 the area included not only the Punjab but also the adjoining smaller Indian States, together with Kashmir, the biggest in area of the States, and noted for its highly salubrious and temperate climate. (4) There is some doubt, particularly for the figures for 1901, as to the precise year or period to which the estimates relate.

It is not possible to say how much allowance has to be made for these factors. However, if the broad indications have any significance it can be stated that the degree of improvement noticed at the lower ages between 1911 and 1931 has not been maintained at the advanced years of life. The 1931 census estimates were arrived at without any regard to the recorded death statistics. On a survey of the mortality rates among the aged in the Punjab during the period 1900–40 we have, however, demonstrated already a downward and statistically significant tendency. We therefore conclude that there has been some improvement in the mortality conditions of old people, and that females have had a somewhat greater advantage.

Summary and Conclusions

The present position of longevity in the Punjab has been studied in relation to other countries and different Provinces of British India. Some relevant information regarding remarkably long-lived persons has been set out, together with figures for the expectation of life for different countries and Provinces. An investigation has also been carried out separately for the two sexes.

As compared with the advanced countries of the world, the Punjab has pitiably low figures of longevity. Further, contrary to the general experience that females have a longer duration of life than males, the women in the Punjab, having been subjected to relatively more adverse circumstances, have not been able to enjoy that duration of life with which Nature equips them. This means the potential loss of male as well as of female children. The study indicates that one of the urgent needs is the making of reproduction an easy and risk-free process by all possible means, not excluding a general social improvement of the female population. Improvements in these directions will be doubly beneficial in that not only will there be a saving of the lives of mothers but the chances of survival of their offspring will increase.

It has been shown that some improvement has been occurring in the mortality rates at the advanced ages of both males and females.

MANCHESTER'S VITAL STATISTICS

Manchester in 1944 had the highest recorded birth rate for twenty years, the lowest general death rate for any year of the war period, and the lowest infantile mortality and puerperal causes mortality on record. Comparing the Manchester of seventy years ago with the Manchester of to-day, both the birth rate and the death rate have been almost precisely halved; the marriage rate has been considerably higher during the war years than during the previous sixty years, and the birth rate, although nothing like what it was before the war of 1914–18, has gone up steadily in each war year. Sixty years ago in Manchester the death rate from measles was 0.71 for every 1,000 persons living, it is now 0.02; from diphtheria it was 0.10, and is now 0.01; from whooping-cough it was 0.68, and is now 0.04; from pulmonary tuberculosis it was 2.42, and is now 0.80; from other diseases of the respiratory system it was 5.41, and is now 2.04; and from diseases of the digestive system it was 1.23, and is now 0.58. On the other hand, the cancer mortality has gone up from 0.50 to 2.09, and the mortality from diseases of the heart from 1.37 to 3.17. Nevertheless, the death rate in Manchester is higher than in England and Wales, and the infantile death rate is 54 per 1,000 births as against 46 for the whole country. But Manchester is in the proud position, not for the first time by any means, of having a maternal mortality rate distinctly lower than for England and Wales as a whole. In 1944 it was 1.83 per 1,000 births, the first time it has ever been below 2.0.

CONGENITAL DEAF-MUTISM IN SCOTLAND

The results of an investigation to determine with a reasonable degree of accuracy the extent to which congenital deaf-mutism varies in its incidence in Scotland are described in a report published by the Department of Health for Scotland. Prepared by Dr. J. A. Grant Keddie, one of the medical officers of the Department, the report, which is a factual survey accompanied by appendices giving statistics of the position in the 35 Scottish counties, was submitted to a subcommittee on nutritional problems of the Scientific Advisory Committee. The full committee considered it to be a valuable contribution to the meagre literature on congenital deaf-mutism and recommended its publication.

In the final stage of this investigation Dr. Keddie submitted to detailed analysis particulars he had secured of 928 sufferers from congenital deaf-mutism who had received tuition at one or other of the schools for the deaf in Scotland during the course of the 20 years ended April 30, 1944. Particular attention was paid to the 781 deaf-mutes born in Scotland during the period 1918–37.

Variable Incidence

The results show that the relative incidence of congenital deaf-mutism is very high in Zetland and Caithness; substantially high in Moray and Nairn, Kircudbright and Aberdeen city; and appreciably high in Wigtown, Ayr, Lanark, Inverness, Angus, Dundee city, and Aberdeen county. At the other end of the scale is Roxburgh, where the relative incidence is extremely low. In Ross and Cromarty, Peebles, Berwick, and Midlothian the incidence is very low; and in Stirling, Orkney, Argyll, Dumfries, Perth, and Kinross, Fife and East Lothian, it is appreciably low. Although it was not the intention of the investigator to draw from the results of the survey conclusions as to why the relative incidence of congenital deaf-mutism is high in certain areas and low in others, Dr. Grant Keddie does direct attention to the following facts: (1) The areas shown to present a high relative incidence are for the most part situated either in the north or north-east of the country on the one hand or on the extreme south-west on the other; (2) many of the areas in question have within their boundaries a considerable number of fishing communities; (3) a number of the areas sparsely populated are at a distance from relatively dense centres of population; (4) the areas presenting a low relative incidence are, on the other hand, situated in the main either on the south-east or in the eastern part of the "Central Belt" and are in most instances predominantly rural in character, while being in the position of convenient access to comparatively large centres of population.

In a preface Dr. Andrew Davidson, Chief Medical Officer of the Department, states that the report "furnishes valuable data which, it is hoped, will point the way to those desirous of prosecuting investigations aimed at finding out any biological or other factor that may contribute to congenital deaf-mutism." Dr. Davidson also emphasizes the fact that "an increasing amount of research into the problems of social medicine is being carried out, and there is a general awakening to the need for the collection and collation of material data by which the nature and extent of such problems may be assessed and lines of approach to their solution suggested." The Department has already published reports on "Health and Industrial Efficiency—Scottish Experiments in Social Medicine" (1943); "Infant Mortality in Scotland" (1943); and "Report on Venereal Diseases" (1944). Copies of Dr. Grant Keddie's report (price 3d.) may be obtained from H.M. Stationery Office, 13A, Castle Street, Edinburgh, or through any bookseller.

S. Siegal (*Ann. intern. Med.*, 1945, **23**, 1) records five cases in patients aged from 13 to 27 presenting an unusual syndrome consisting of paroxysms of intense abdominal pain and fever as high as 105° F. Severe prostration, marked signs of peritoneal irritation as well as melaena and vomiting were invariable accompaniments. Urticaria and pain in the chest of a pleuritic character might occur. The onset of the disease was characteristically in early life and attacks recurred over many years. The general condition remained unimpaired. The disease was probably related to allergy.

Nova et Vetera

WILLIAM PROUT: PHILOSOPHER-PHYSICIAN

Though the atomic bomb has renewed interest in the history of atomic theory, no reference has been made to the pioneer work of the physician William Prout. Yet his hypothesis of recurring characteristics in the elements which could be seen when they were placed in the order of their atomic weights led to the formation of Mendeléeff's Periodic Law, which in its turn received its rational explanation in the electronic structure of the atom. Moreover, just as Le Verrier and Adams were enabled to predict the finding of the planet Neptune in the solar macrocosm, so the periodic law predicted the characters of as yet unknown elements in the atomic microcosm. And there can be little doubt as to which discovery most influenced human thought and action.

William Prout was born in 1785 of an old Gloucestershire family. His education was entirely neglected until he was 17, when on his own initiative he placed himself under the tuition of a clergyman in Wiltshire, who sent him on after a time to the Redland Academy at Bristol, where he made such progress that he was advised to go to Edinburgh to study medicine. He graduated M.D. in 1811, and then worked at the twin hospitals of St. Thomas's and Guy's. Always interested in organic chemistry, he gave a course of lectures there on "animal chemistry," which Sir Astley Cooper diligently attended. He proved the chemical nature of urinary calculi and applied this to the treatment of urinary disorders. He was first to show that the kidney does not form urea but merely removes it from the blood.

In 1831 he delivered the Goulstonian Lectures before the Royal College of Physicians, of which he had been elected a Fellow in 1829. His subject was "The Application of Chemistry to Physiology, Pathology, and Practice," in which he showed himself a pioneer in the biochemical approach to medicine. In 1834 he published the final version of his views in his book *On the Nature and Treatment of Stomach and Urinary Diseases.* This was rightly regarded as marking an era in the history of the subject. He showed that the acid of the gastric juice was hydrochloric acid. That the stomach secreted a mineral acid came as a great surprise, and it was not until a good many years later that Maly explained it as the result of the interaction between sodium chloride and acid sodium phosphate. Prout's discovery, added to Wöhler's synthesis of urea, helped to break through the previously existing barrier between organic and inorganic chemistry.

Prout was also greatly interested in meteorology and spent much money in devising elaborate apparatus for his researches. The English standard barometer now in the possession of the Royal Society was designed by him. Throughout, his work was marked by two main characteristics—the power of accurate observation and the capacity for forming wide generalizations. But so little self-seeking was he that he often allowed others to take the credit for his ideas. Particularly so was it with Liebig, who adopted many of his views and sometimes marred them in the taking. Thus on the chemical and physiological relationships between urea and uric acid Liebig was wrong and Prout was right. But the fame of Liebig was so great that for years it obscured the merits of Prout, even in England, which, however, has so often hesitated to accept a scientific discovery made at home until it is re-imported from abroad.

Prout was reserved and retiring, and this was increased by the deafness which afflicted his later life. He was described as of middle height and of slim figure, with delicately chiselled features which expressed "benevolence with great intelligence." He inspired confidence in his patients by the gentleness of his manner. Always scrupulously dressed and groomed, he was a striking figure in any assembly.

He died in 1850. Considering the width of his philosophic generalizations and his many important discoveries, posterity has done scant justice to his merits. We have gathered the fruit of his labours but forget the debt we owe to the gentle philosopher-physician of Sackville Street.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY

Papers and Cases

An Ordinary Meeting of the Society was held in June, when a number of interesting communications were made.

ARTERIAL THROMBOSIS AFTER ECTOPIC PREGNANCY

Dr. **ROBERT NEWTON** described a case of femoral thrombosis after an operation for a simple ectopic pregnancy. The patient, aged 36, was sent to hospital because of mild pelvic pain. Three weeks before, she had had for 24 hours right-sided abdominal pain, a temperature of about 99.5° F., and vomiting. The practitioner diagnosed mild appendicitis and kept her in bed. Menstruation was due at that time but she did not bleed until ten days later, which continued from then until admission to hospital nine days later. She gave a history that the pain, which had settled down, had recommenced six days before in the left iliac fossa. On admission the pain had disappeared and there was no rigidity. The cervix was softened and the blood pressure 110/80; she was admitted to a gynaecological ward. Two days later a mass was palpated in the left iliac fossa and a tentative diagnosis of ectopic pregnancy was made. Under anaesthesia the mass was confirmed and was felt to rupture during palpation; a needle in the pouch of Douglas produced fresh blood. On opening the abdomen a left ectopic pregnancy was found, and the left tube and ovary were removed. The actual mass was quite small; it was formed of the ovary and tube infiltrated with old blood clot and adherent to the left side of the pelvis. A moderate amount of fresh blood was found free in the abdomen. The patient showed signs of collapse half-way through the operation and again on reaching the ward. Sedatives and salines were given in the early afternoon, and again in the evening. It was probably these sedatives which concealed the onset of the thrombosis. She made no complaint, sleeping through the night, but in the morning, on awakening, she felt some mild pain around her knees and could not feel her feet and legs. When examined she was found to have rigor mortis from the lower part of the thighs downwards. There were no femoral pulses, and she had anaesthesia to a level corresponding to the second lumbar nerve on the left side and the third lumbar on the right. The picture was of obstruction at the aortic bifurcation of both common iliac arteries. It was obviously a desperate case, and the treatment was considered from the point of view of whether life could possibly be saved; which really depended on the presence of an embolism at the aortic bifurcation. If this were removed it might be possible to amputate the legs at a very high level. Indirect approach was used. Both femoral arteries were exposed, both were contracted and filled with blood clot. The blood clot was removed and ureteric catheters passed into the aorta. No fresh blood could be removed by suction. The left internal iliac artery was exposed. No pulsation was felt and no clot could be milked down it. The patient died next day. Post mortem, thrombosis involving both femoral arteries and the lower end of the aorta was found, and there was no embolus. An old clot could be made out on the inner side of the internal iliac artery where the ectopic mass had been adherent.

Points of interest were the rarity of the occurrence, the importance of making early diagnosis, the simple way in which this was frustrated in this case by the shock and the giving of mild sedatives; the difficulty in making a diagnosis between embolism and thrombosis; the decision as to the direct or indirect approach; and, in the case of early diagnosis, whether heparin and dicoumarin (which were given in this case) would be of use.

ALDRIDGE'S OPERATION

Dr. **J. W. A. HUNTER** read a paper on Aldridge's operation for urinary stress incontinence. The problem of the cure of imperfect urinary control has yet to be solved. There were many operative procedures, and this denoted all the more the uncertainty of cure of any one of them. Varying degrees of cystocele were often found to be present, but it was by no means an invariable accompaniment. Inelastic scar tissue sometimes replaced the urethral supports and sphincter. Probably the commonest procedure was the simple plication of the urethral sphincter by the method of Kelly or Baldy. Two cases treated in this way with a good result were described by Dr. Dougal in 1926. More elaborate operations of a similar nature had been described by Royston and Ross. Advancement of the urethra was devised by Pawlik, and twisting the urethra through many degrees was advocated by Gersuwy—the latter a highly dangerous procedure. Failure of these operations led Miller to devise the use of the pyramidalis muscles as a sling, being pulled down behind the pubis and united around the bladder neck. The pyramidalis often being of poorly developed structure, Aldridge in 1942 devised a modification using strips of abdominal fascia drawn through the rectus muscle and sutured to form a sling under the bladder neck. With this technique Dr. Hunter treated the two cases which he reported.

A median incision was made just below the external urinary meatus to the bladder neck, and the vaginal epithelium widely dissected on either side. With a transverse incision across the lower abdomen about 2 in. above the symphysis two strips of fascia were raised on either side about 4 in. long and 1 in. wide, leaving a median attachment of about 1 in. The gaps in the fascia were sutured. A curved sinus forceps was passed up on either side of the bladder and through the rectus muscle. The strips were drawn down and united under the bladder neck with fine silk sutures. The vaginal epithelium and abdominal wound were closed and a self-retaining catheter inserted and left in for about seven days. Sulphadiazine was given to prevent urinary infection.

UNILATERAL DYSMENORRHOEA

Prof. **A. M. CLAYE** reported a case of unilateral dysmenorrhoea associated with congenital abnormality. The patient, aged 27, was first seen in August, 1944. The cycle at that time was $\frac{4-5}{42-56}$ with somewhat excessive loss and clots. She had always had dysmenorrhoea confined to the right side of the body, felt chiefly in the right iliac fossa and radiating down the right thigh; it began with the onset of menstruation and persisted through the first two days of the period, associated with vomiting and frontal headache. Pelvic examination showed a small mass on the right side, apparently to the right of the uterus. A skiagram after lipiodol injection revealed the body of the uterus lying to the left, and only the left tube filled satisfactorily. On opening the abdomen a double uterus was found, the left half being continuous with the cervix and the right half apparently ending blindly and having no connexion. The right ovary was three times as large as the left. Small blebs of (?) endometriosis on the surface of the left ovary were cauterized. Right salpingo-oophorectomy was performed and the right portion of the double uterus excised. The pathological report was as follows: "The right ovary contains at least six follicular cysts in the cortical stroma, and a blood cyst 1/2 in. in diameter with a thin lutein margin. The right portion of the uterus was 1½ in. long, apparently lined with normal endometrium. There was no outlet apart from the tube and it contained no blood." Histologically the uterus showed mural endometriosis. In conclusion the speaker noted that Prof. Miles Phillips had in 1935 described unilateral menstrual pain occurring in the case of localized cornual adenomyoma and haematometra in the rudimentary horn of a double uterus. In each case the right side was involved, as in this one, in which the mural endometriosis might have contributed to the pain. Operation resulted in complete cure.

WATERS'S OPERATION

Mr. **C. McINTOSH MARSHALL** showed two colour films of Waters's operation (extraperitoneal Caesarean section). He had no desire, he said, to win support for this type of Caesarean section. Had it appeared some twenty-five or thirty years ago it must have won a definite place for itself and much less would have been heard of the "lateral approach"—the operations of Latzko, Döderlein, Kustner, and others. But with the advent of the sulphonamides and penicillin the use of all extraperitoneal operations would probably tend to decrease rather than increase. E. G. Waters described the operation in 1940 (*Amer.*

J. Obstet. Gynec., **39**, 423). Waters wrote thus: "Theoretically the most highly desirable extraperitoneal operation would (1) avoid opening the peritoneum during or after extraction of the baby, (2) avoid injury to the ureters, (3) avoid the easily infected cellular tissue lateral to the bladder, (4) give full view of the separated tissue and the operative field, (5) give ample room for extracting any size foetus, (6) permit careful two-layer closure of uterus and thorough inspection of venous bleeding, if any, (7) leave the patient with a good uterine and abdominal wall."

The operation derived from the Physick principle and from the attempts of Frank and Sellheim to dissect the peritoneum off the front and top of the bladder. In contradistinction to these attempts the reason why Waters's operation was so successful and technically simple rested on the fact that not only was the peritoneum raised but with it the whole thickness of the bladder fascial covering. The operator was no longer dealing with a thin translucent and diaphanous membrane, but was raising by dissection a relatively thick mass of tissue. Apart altogether from the question of infection, certain positive claims could be made for the operation: "burst abdomen" would never occur, intraperitoneal adhesions would not arise, ileus would be less likely, swabs and instruments could not be left behind. In conclusion, Mr. Marshall stated that he had no intention of using this operation extensively or of wavering in his loyalty to the transperitoneal lower-segment operation with a deeply placed transverse incision. On rare occasions, however, he would meet a truly mismanaged and gravely infected case; it was in such that he would put to use his acquaintance with the Waters operation, and by doing so he believed he would be conferring on the patient a greater degree of safety than he could offer her by any intraperitoneal operation.

Correspondence

The Shackled Mind

Sir,—Dr. F. M. R. Walshe in his thesis published in your issue of May 26 (p. 723) gives a very interesting annotation of the deficiencies of modern medical practice in its attitude towards constructive thought. But he apparently suffers from similar deficiencies. He explains the deficiencies of the medical mind—his collection of the superficial facts is excellent; however, his analysis of them and subsequent conclusions are hardly integrating thoughts as they are so incomplete.

With the superficial facts before us (Dr. Walshe mentions that they have been expounded by former prominent medical men) we must in the light of modern knowledge analyse them. In so doing we find that there are few members of our profession whose minds are free from the shackles of "blind acceptance of authority." Our claims to have made medical practice a science are false, as we have failed even to develop a scientific outlook. Medical graduates rarely develop a scientific mind—a mind which can question all except absolute truths, a mind which will not accept as absolute truths dogmas and doctrines laid down by so-called "authorities." Collectively we are still as tardy to accept new, scientifically proven fundamentals as were our forebears in accepting Pasteur's or Lister's work. Dogmas and customs sway our judgments, far too often negating scientific advances. How few of us stop to analyse the physiological basis of a symptom or a sign. If we do not make such simple deductions and integrations how can we hope to analyse and integrate facts in the as yet relatively unexplored jungles, such as brain function or the problem of cancer?

Why should we not all have an unshackled mind, thinking and reasoning in a truly scientific way? We have all had a tertiary education in the sciences. Our very training in present society from the time we first learn to understand our parents is not along scientific lines, but is to make us believe in the dogmas of "authorities," as, for example, the idea of blind acceptance with which we are imbued during our religious training. Medicine does not suffer alone from the stultifying influence of the unscientific mind. The whole social and economic structure of our society is retarded in a similar way. The "shackled" mind is a disease of our present social, economic, and educational systems, just as is the ingrown toenail or constipation a product of modern civilization.

Do we all realize the profound influence of money on medical science? The medical practitioner has a high standard of living in depression or boom—a big incentive to many to enter the profession. A verbal census of students at Sydney University in 1940 showed that of the first-, second-, and third-year students approximately 80% were in the faculty because M.B., B.S. offered either a very sound economic security or a prominent social status—these ideas being imparted by parents. (Apparently few study medicine because they are interested in it.) So within our ranks are a majority who, during their student days at least, sought only technical knowledge and not a scientific training. These seek to conserve their economic interests, so developing a conservation as opposed to a scientific outlook towards medicine. New ideas are irksome unless readily commercializable. Hence the profession, at least subconsciously, slowly progress.

Then there is the economic position of our true scientists. The salary of the researcher is so small. A scientist must live. He, or she, desires normal associations with fellow men and women, a home and a family. So much time is wasted in planning ways and means of meeting essential economic commitments and ensuring economic security. Too often the research is cast aside.

By educational and social reform we must break the shackles of the mind from within and without, producing unbiased minds in an unbiased world, encouraging original integral thought among our young scientists instead of blanketing their ideas. We can only hope for integration to keep abreast of the compilation of facts if we, the present generation at the helms of society and science, steer our ships into the calm waters of a world where money is no longer our overlord, a world where our minds think and reason scientifically, released from the serfdom imposed by economic exploiters of superstition and prophecy. To succeed with the integration of medicine we must bring an inquiring mind to all our problems. The researcher with a trained scientific mind sees his specialty in its true perspective. It all resolves itself into the fact that the failures of medical science to interpret its jargon of facts is a sign of a faulty educational system, the product of our present economic and social structure.—I am, etc.,

Cairns, Queensland. Ronald B. Wiles.

Medical Education: Need for Personnel

Sir,—The present change-over from war to peace brings into focus the educational conditions in our universities and medical schools. They form a "key" position in our reconstruction programme. For this reason they need special consideration by those responsible. This need is reinforced by the report of the Goodenough Committee on Medical Education of 1944, and the recommendations of the University Grants Committee now being made to the universities and medical schools that they shall increase their efficiency by creating new departments, by enlargement of establishment, and by greater expenditure on salaries, equipment, and maintenance, with particular reference to research. During the war the establishments have been depleted, postgraduate and clinical training cut down or abolished, and honours science degrees in medical subjects (physiology, biochemistry, anatomy, and pathology) practically abolished in all universities except Oxford and Cambridge. In addition, the Services have rightly had first call on the newly qualified and better graduates.

If the recommendations of these two committees are to be fulfilled (the first stage of these changes operated from Aug. 1, 1945) the present policy governing the direction of medical graduates must be modified. There must be a recognition that with the change from war to peace the requirements of medical education take priority over those of the fighting Services. This means that medical scientists should be demobilized as early as possible, in virtue of their specialist knowledge. It means that newly qualified practitioners who desire to specialize in scientific medicine and who are qualified to do so should be given every encouragement to apply for university posts. Since the graduates from Oxford and Cambridge are too few to meet the demand it is only in this way that suitable individuals can receive a training in laboratory subjects. We can then, at least, commence to make up the grave lack of young medical scientists which has resulted from the paramount needs of the

Services during the war period. Recently, numerous appointments have been advertised in your columns, of chairs, lecturers, and demonstrators. The universities concerned go to considerable trouble and expense to select the most suitable candidate from the limited fields available. Having made their selection, the Central Medical War Committee on the recommendations of its Services Committee not infrequently calls up the selected candidate, regardless of the work and grave trouble they are causing to those responsible not only for medical education and university research but also for carrying out the recommendations of the Government.

We do not now desire to dispute the wisdom or the necessity of such decisions in the past. We do, however, most strongly urge that the change from war to peace in its first phase—namely, the phase of reconstruction—requires a different policy. The essential difference is that in this stage of the peace reconstruction and its needs take precedence over the fighting Services and their requirements. Among the needs of reconstruction the staffing of our universities and medical schools is not the least important, since it is only by attention to this aspect that a continuous adequate supply of well-trained medical graduates can be provided for the general-practitioner, consultant, and public health services. It must be noted that during the war not only has the establishment of the medical schools been depleted and stream-lined, but also the period of compulsory clinical training reduced from 3 to 2½ years. There is no peacetime justification for this policy, but rather for its immediate reversal in the interests of the community.

The needs of the universities and medical schools must, therefore, be regarded as having the same degree of urgency as the needs of other branches of civil medicine. This applies whether in determining the order of release of medical men and women from the Navy, Army, and Air Force or in allocating newly qualified practitioners between the Services and the various types of civilian medical practice. If the universities and medical schools are to play their part in giving the best possible training to students their needs in personnel must be fully appreciated not only by their own governing bodies but also by those Government Departments which guide the general policy of the University Grants Committee and the Central Medical War Committee.—We are, etc.,

Professor of Physiology, University of London,
London School of Medicine for Women.

Trichlorethylene

SIR,—From a persual of your correspondence columns during the past six months it would appear that some misapprehension exists among occasional anaesthetists as to the effects and limitations of trichlorethylene. I should therefore be grateful if I might summarize the position very briefly.

It is now recognized that trichlorethylene is an admirable agent for the induction of general anaesthesia (preferably with nitrous oxide and oxygen) and for the maintenance of a light phase of narcosis when complete muscular relaxation is unnecessary—for example, for many dental and cranial operations, radical mastectomy, multiple excision of varicose veins, etc. The maintenance dose is much less than is often supposed and rarely exceeds a few minims per hour. The characteristic smell of the drug should be just perceptible in the inhaled mixture, and it may be difficult on some types of apparatus to give a sufficiently low concentration. When administered in this way respiration is quiet and slow while recovery is extremely rapid, with gratifyingly few after-effects as compared with ether. On the other hand, if attempts are made to "push" trichlorethylene in order to secure relaxation for upper abdominal or orthopaedic surgery, tachypnoea and other signs of overdosage will soon become evident and recovery may be delayed. Relaxation should be obtained by recognized methods, such as suitable nerve or field blocking, the intravenous injection of pentothal (probably soon to be ousted by curare), or by a change-over to some other inhalation anaesthetic such as ether. It is worth noting, with so many fire hazards in modern operating theatres, that trichlorethylene vapour can be regarded as non-inflammable under normal conditions in this country.

As a general analgesic the drug is probably unsurpassed in efficiency by any other in use at the present time. Two types of inhalers, using air as the vaporizing agent, are in common use. One is the "draw-over" type—e.g., Marrett's and Freedman's—and the other the "blow-through" variety, such as Hill's. Both can be used by the patient himself and are most efficient for many minor surgical procedures and in midwifery.

As regards post-anaesthetic toxic effects, nerve palsies have followed trichlorethylene given in a closed circuit with unsuitable soda-lime which became unduly hot. Under these circumstances a chemical reaction between the two substances can occur and toxic products be formed. To be on the safe side it is therefore recommended never to use a closed circuit with trichlorethylene. One case of suprarenal haemorrhage and liver necrosis has been reported after trichlorethylene had been given as an analgesic in labour. It is doubtful, however, if the drug played any part in the condition.

Arrhythmias are common during narcosis with trichlorethylene as with all inhalation agents. Recent work with the electrocardiograph suggests that the only arrhythmias to have much significance during anaesthesia are the multifocal ventricular type, which, in the case of chloroform, are known to be occasionally followed by ventricular fibrillation. Although this type of arrhythmia occurs in about 10% of patients anaesthetized with cyclopropane or with trichlorethylene, primary cardiac failure is almost unknown with either agent, so that it seems reasonable not to take pulse irregularities too seriously. After using trichlorethylene continuously for over 5 years I have yet to see any serious harm caused to a patient by it, but it is essential to recognize and respect its limitations.

May I conclude by suggesting that the occasional anaesthetist should at least read the literature relating to new drugs and methods before embarking on their use. Failure to do so results at best in disappointment and at worst in disaster.—I am, etc.,

Hill End Hospital, St. Albans. C. LANGTON HEWER.

Ludwig's Angina

SIR,—In cases of Ludwig's angina Major J. H. West (Sept. 15, p. 369) advocates nitrous-oxide–oxygen anaesthesia as a preliminary measure to facilitate the passage of an intratracheal tube. In the same communication he describes my warnings as to possible failure of intratracheal intubation as theoretical. I should like to assure Major West that my objection to any form of general anaesthesia in this emergency is the direct outcome of practical experience.

Regarding N_2O, many years ago my anaesthetist was severely reprimanded. The words of the coroner are engraven on the tablets of my memory: "Surely you now realize that nitrous oxide is a spasmotic anaesthetic, and should never have been given in a case of threatened obstruction to the air passages."

Since my communication in the *Journal* of March 17 (p. 384) I have received letters from three surgeons and a verbal communication from another describing fatal issues as a result of employing inhalation or pentothal anaesthesia in cases of Ludwig's angina. Consequently I feel impelled to plead that my advocacy for regional block anaesthesia in this condition is not, as has been suggested, an arm-chair theory, but so highly practical as to merit the term "vital."—I am, etc.,

London, W.1. HAMILTON BAILEY.

Sciatic "Neuritis"

SIR,—Dr. MacDonald Holmes and Mr. Sworn (Sept. 15, p. 350) quote my remark that in no case of sciatica had an inflamed and swollen sciatic nerve been visually demonstrated as the cause. At the time this was made I had been looking in the journals for some such observation, which I thought might have been recorded when one of the methods of treating sciatica was to mobilize the sciatic nerve after exposing it by operation. I could find no instance in which changes characteristic of active inflammation were described. My search was by no means complete, and I thought that my provocative statement might bring to light some case record which I had missed, but so far as I am aware none has been forthcoming.

Whether the statement for which I am responsible is correct or not, Dr. Holmes and Mr. Sworn err in applying it to the lumbo-sacral nerve roots. Congestion and swelling of the lower lumbar or first sacral roots have been previously noted in cases of sciatica in which the roots have been exposed at operation. Dr. J. S. Barr (Dec. 17, 1938, p. 1247) drew attention to this finding in association with prolapsed disk, and I have seen it demonstrated, as Dr. Holmes and Mr. Sworn describe, when no protrusion has been discovered. Whether in these latter cases the congestion and swelling are due to oedema from pressure by a protrusion which is not apparent at operation or is of true inflammatory origin is a question which has not been finally settled.

However this may be, Dr. Holmes and Mr. Sworn are mistaken in supposing that they have observed a lesion which, in the paper to which they refer, I considered had not yet been seen by human eyes. Lumbo-sacral "radiculitis" would, I submit, have been a more appropriate title for their paper than sciatic "neuritis."—I am, etc.,

London, W.1. C. P. SYMONDS.

SIR,—I was interested in the article by Dr. MacDonald Holmes and Mr. Sworn on sciatica. I am an orthopaedic surgeon, but, in common with some others, I take a great interest in the physiotherapy side of our work, and thus I have not a confirmed surgical bias, and in the course of a year of both orthopaedic and physiotherapy practice I see and deal with a large number of cases of sciatica. I am not, myself, entirely convinced with the latest idea that all cases of sciatica are caused by a prolapsed disk. I was present at the Royal Society of Medicine meeting when Dr. Symonds and Mr. Pennybacker put forward the above views, which were later strongly criticized in subsequent correspondence in the *Journal*. Anyone who reads American literature would be led to assume that the diagnosis of the disk prolapse is easy, yet I find myself able to cure most cases of sciatica by manipulation or physiotherapy, though, as a surgeon, it would be equally easy for me to perform laminectomies. Thus it is with great interest that I note that Mr. Sworn found that in only 55% of the cases which he subjected to laminectomy was a prolapsed disk found. I think the explanation of the three cases that he describes, which certainly present the picture one would expect from a prolapsed disk and in which, upon operation, none was found, were cured because Mr. Sworn, in performing his laminectomy, had necessarily cut through the ligamentum flavum.

In an excellent article in the *Journal of the American Medical Association* in February of this year Mr. Keeghan describes a series of similar cases in which he noted that the free edge of this ligament in some persons may form a thickened band which may rub against the dural sheath of the outgoing lumbar spinal nerve. Mr. Keeghan ascribes the cure of numbers of his cases where no prolapsed disk was found to the fact that the surgical approach of itself cured the friction on the nerve. This article, and a previous one by the same writer in the *Journal of Bone and Joint Surgery* for April, 1944, are worth more notice in this country.—I am, etc.,

London, W.1. G. O. TIPPETT.

SIR,—In their article on sciatic "neuritis" (Sept. 15) Dr. J. MacDonald Holmes and Mr. B. R. Sworn have described the results of three cases of operation for ruptured intervertebral disks. While adhering to the belief that the most common cause of chronic pain in the distribution of the lumbo-sacral nerve roots is the result of a ruptured disk, they cite these cases as being instances in which a sciatic neuritis has occurred idiopathically and not in the presence of a traumatic lesion. Two of the cases described gave a history of severe strain at some time prior to the onset of the symptoms. The third, that of the housewife, could probably also have given a history of severe strain or, at any rate, of a series of lesser strains giving rise to a cumulatively traumatic effect.

With such histories it would seem correct to assume that some tangible lesion other than that of a ruptured or prolapsed disk had occurred. It is probable that this lesion was a simple minor rotatory displacement of the fifth lumbar vertebra on the sacrum; in other words, a lumbo-sacral strain had been produced. This would give rise to all the symptoms of a sciatic neuritis which could not be explained in any other way. Contingent on the injury, the vertebral strain, spasm of muscle bundles would take place, and, by pressure on the spinal nerves themselves, cause an inflammatory process ascending to the nerve roots. A radiculitis with its attendant symptoms would result.

The theory of the mechanical compression of a nerve root from narrowing of the intervertebral foramen offers no better an explanation for the causation of radiculitis following a vertebral strain than it does in the case of a ruptured or prolapsed disk. The spines of patients suffering from marked scoliosis show very appreciable diminution in the size of their intervertebral foramina on the side of convexity without the development of peripheral symptoms.

On the assumption that the three cases referred to were examples of lumbo-sacral strain the initial steps taken for their cure and for an accurate diagnosis might well have been manipulative rather than operative. In any event the label does not seem to matter very much. Clinically and radiologically the diagnosis of a prolapsed or ruptured disk is surmise. The diagnosis is only confirmed or negatived after operation. Radiologically the diagnosis of lumbo-sacral strain is also surmise. Clinically there are such guiding signs as tenderness to the affected side of the spinous process of the fifth lumbar vertebra and accompanying muscle tension. The suggestion is that, in order to establish a diagnosis and, more pertinently still, probably to effect a cure, a specific manipulation or series of manipulations if necessary should be carried out before operative measures are considered.

A brief description of the technique of the manipulation recommended has been given elsewhere ("Vertebral and Sacro-iliac Strain in the Soldier," *J. R.A.M.C.*, Jan., 1944). If the manipulative procedure succeeds, the diagnosis—that of sciatic neuritis due to lumbo-sacral strain—becomes apparent *post hoc*. If it is unsuccessful resort may have to be made to the hazards of laminectomy.—I am, etc.,

St. John's Wood, N.W.8. E. GORDON FLEMING.

Domiciliary Midwifery and the Family Doctor

SIR,—I read with interest the article on domiciliary midwifery and the family doctor (Sept. 1, p. 294). I fully realize that the sentiments expressed are strongly held by its authors, and also that their intention in writing it was to stress their disagreement with the report of the Royal College of Obstetricians and Gynaecologists. On the contrary, they put forward a detailed argument in favour of a scheme similar to that outlined in the Maternity Services (Scotland) Act, 1937. At the outset I would like to point out that I have no personal knowledge of the workings of this Act, and equally to stress that this letter is not written as a result of any preconceived prejudices of my own, but merely in a spirit of honest inquiry. I am rather surprised by some of the statements which they so confidently make, and in order to save space I have put my queries in tabular form.

"*Doctors all over the country are perturbed.*"—What proof can they give that this is in fact the case? My own experience has been that a large proportion of medical men, in England at least, have little liking for midwifery, and are only too pleased that some of the burden should be taken from them in the manner suggested by the College.

"*Increased hospitalization.*"—They imply that patients prefer to have their confinement at home. Most of my own private patients, on the contrary, express a strong preference for a hospital, and the main difficulty is to find sufficient accommodation.

"*We have also tried to show that many of the adverse criticisms of our work as practical obstetricians have not the support of recent investigation.*"—I have most carefully read and re-read their article, but cannot find any proof of this statement. Such proof would require massive statistics, and without such support a statement of this sort loses its meaning.

"*The family doctor has already realized that the more careful and skilful his ante-natal examination the less is the trouble he has at the confinement.*"—Surely this is the very argument in favour of ante-natal care being carried out by doctors with some extra training. I am firmly convinced that *adequate* ante-natal care requires much more practice than can be obtained by the average general practitioner.

"*We contend that successful midwifery depends upon a sense of confidence and an absence of fear.*"—I find it difficult to see how such a state can influence the incidence of posteriors, breeches, transverse lies, toxaemias, ante- and post-partum haemorrhages, cephalopelvic disproportion, and so on. But surely it is these very conditions which so strongly influence the outcome for both mother and baby.

"*Mastitis, phlegmasia alba dolens are more common in hospital practice than in general practice.*"—With the first statement I disagree. In the last three years I can call to mind 2,500 confinements which were conducted at hospitals with which I am connected, and in one case only did a puerperal mastitis develop. This was remarked upon at the time by the ward sister concerned as being something quite abnormal. On the contrary, I have seen in the same time several very severe breast infections which occurred in domiciliary practice. As to phlegmasia, etc., it is obvious that any deviation from the normal is likely to occur more frequently in hospital than in domiciliary practice, as difficult cases on the whole tend to be sent there. One might as justifiably maintain that maternal deaths are practically unknown in the private practice of midwives, as a medical man has invariably been summoned long before such an occurrence, and the onus is transferred to him.

"*All are agreed that forceps were frequently used when they should not have been.*"—This is, I think, only too true. One general practitioner whom I know very well admits that in his lifetime he applied forceps well over 2,000 times. In that time he attended about 3,500 confinements. What I cannot understand is the argument that many general practitioners now go to the opposite extreme because of the campaign against this wholesale abuse of forceps, and as a result allow suffering, and even the loss of infant life, to occur. Surely this implies lack of knowledge, confidence, or conviction.

"*Tears of the cervix.*"—It is suggested that anaesthesia may act as a preventive of such cervical injuries. Can the authors produce any really adequate evidence that this is in fact the case? On the contrary, can they give any definite proof that forceps application before full dilatation of the cervix is not still only too common in some quarters?

"*The widespread and unnecessary use of Caesarean section or of induction of labour . . . led to protests from influential quarters.*"—This is of course true, though it does not by any means follow that such unnecessary use is by any means limited to obstetric specialists.

"*Errors of judgment.*"—The writers state that, although anyone, however experienced, may make an error of judgment, yet such do "not happen in the commoner difficulties, but in sudden and unforeseen emergencies." All will agree, I think, that posterior positions of the occiput and deep transverse arrests of the head are among the commonest obstetric difficulties. It is my experience—and I am certain that other obstetricians must have had a similar one—that it is these common conditions which so often remain undiagnosed, and to which one is called in consultation.

"*Domiciliary midwifery . . . is safer in all but a small minority of cases than institutional midwifery.*"—I would only counter this statement, made without statistical backing, by another statement, also based on opinion alone. My own experience has been that the hazards of any obstetric difficulty, however slight, assume greatest proportions in the patient's own home, greater proportions in a nursing home, and smallest proportions when the delivery is in a hospital. All obstetricians of my personal acquaintance have repeatedly made a similar observation.—I am, etc.,

London, W.1. D. G. WILSON CLYNE.

SIR,—I have read with interest the paper by Lieut.-Col. Dale Logan and Dr. MacKenzie, with some of which I am in agreement. I do feel, however, that many of their arguments are open to criticism. Their opening paragraph is a misrepresentation of the object of the Royal College of Obstetricians and Gynaecologists. The object before the Council was to provide a *uniform standard* of obstetrics for the whole country. No one in the profession can deny that the standard of treatment varies considerably in different parts of the country and with different individuals.

The writers suggest that the Royal College is usurping the functions of the General Medical Council. I would suggest that they read the Lloyd Roberts Lecture by Sir Comyns Berkeley, published in 1929 in the *Journal of Obstetrics and Gynaecology of the British Empire*. The record of the General Medical Council regarding obstetric teaching is bad. Any improvement in obstetric teaching has been the result of the General Medical Council's yielding to pressure brought to bear by the teachers and teaching schools.

Had either Lieut.-Col. Logan or Dr. MacKenzie been a resident in a maternity hospital in the early '20s (as they may have been, although it is not noted in the *Medical Directory*) and had the opportunity of seeing many women admitted mutilated as the result of misapplication or lack of judgment in the use of forceps, the ruptured uteri following abuse of pituitary extract, etc., they might view domiciliary practice with a less friendly eye. Midwifery has improved in the interval for, I believe, the following reasons: (1) Better training of medical students. (2) Better training of midwives. (3) Better co-operation between family doctors and consultants. (4) Efficiently managed maternity hospitals. The most marked improvement has occurred since the outbreak of the war. Is this not due to the fact that because so many practitioners were serving with H.M. Forces it was necessary to concentrate maternity cases in institutions where the greatest number of expectant and parturient women received skilled attention from the limited specialist personnel available?

In the paper the fear is expressed that the general practitioner is being excluded from midwifery. My experience may be purely a local one and not representative of the British Isles in general, but in recent years fewer of the younger practitioners are undertaking midwifery. If they wish to avoid the irregular hours, loss of sleep and family life, who can blame them? Many of the younger doctors who are practising midwifery have, unlike their predecessors, held resident obstetric appointments before embarking on domiciliary practice. I feel sure that this type of practitioner will be encouraged and included in the maternity service suggested by the R.C.O.G.

Personally I find the relation between the obstetric consultant and the family doctor remarkably improved. Now, a consultation is called for in most cases of doubt, not, as in the past, to cover a mistake already made. I admit there is a small minority of obstetric consultants who view a case with a surgical rather than a physiological eye, and thereby bring discredit on some life-saving operations, but it is unfair to suggest that consultants have not enough experience of normal midwifery. Their training and appointments of necessity ensure that they have this experience. No man has the right to regard himself as a consultant unless he has lived for at least two years as a resident in a large maternity hospital with an extensive domiciliary practice attached.

The paper raises a most important point regarding the relief of pain. I agree with the writers that this should not be delegated to nurses. I feel sure that if in every area a team of skilled obstetric anaesthetists—for obstetric anaesthesia is a very skilled branch of anaesthetics—were available for either midwife or doctor one would have gone a long way towards solving many of the difficulties and removing some of the dangers of obstetric practice.

I agree with the authors that a patient is safer, from the point of view of sepsis, in her own home than in some institutions. To improve the standard of efficiency of every maternity institution—nursing home or hospital—must be the object of everyone concerned with midwifery. The authors cannot surely be serious when they suggest that a confinement at home is safer than in an institution. Who can tell which patient, even at a normal confinement, will not have a post-partum haemorrhage or retained placenta? The ease with which a blood transfusion can be obtained in an institution must have saved many lives. The presence or absence of neonatal infection is an indication of the efficiency of the nursing in any institution. I know one private department with which I am connected where the maternal mortality in 1,243 cases has been 1.6 per 1,000 (one of these a pulmonary embolus) and where the neonatal mortality is 14 per 1,000. This department is in the sole charge of a skilled nursing staff and five of the much-maligned consultants.—I am, etc.,

Belfast. C. H. G. MACAFEE.

SIR,—The lack of any proposals in the White Paper for improving the existing maternity services made it inevitable that some such report as that of the Royal College of Obstetricians and Gynaecologists should be produced. If "doctors all over the country are perturbed by the recent report" it should be realized that just as many who were looking forward to seeing new ideas on the maternity services incorporated in the White Paper were bitterly disappointed at the omission. It seems to me that the article by Lieut.-Col. Dale Logan and Dr. MacKenzie has been written by men who work predominantly in rural areas, and, of course, rural midwifery is on a very different footing from urban practice. In rural midwifery a doctor has to be good, but modern urban practice has moved very far from the patriarchal scheme of things outlined by Dr. MacKenzie in his contribution to the discussion on ante-natal care in the *Journal* of Aug. 16, 1924 (p. 271).

Surely the report of the College is eminently reasonable. It is mainly a statement of the shortcomings of the present services in both training of personnel and the conditions in which they have to work; how some of these defects of training and working conditions have been remedied and how they could be still further improved. (I, myself, up to the day I qualified had never applied forceps to a living person, and some of the house-surgeons who come to the hospital where I work have not done so either and the best have done so only a few times, and this in 1945.) We ought to support wholeheartedly any scheme that helps us to increase our training and competence and provides better facilities for us to work under. Let us see how the present system does work.

I have been many years in practice and have attained to a semi-specialty on the staff of a hospital that last year catered for 1,085 admissions and 961 deliveries. These figures are not loaded with emergencies sent in from outside. They are practically all booked cases—i.e., a totally unselected section of the community of the same category as those who decide to have their baby at home with a municipal or private midwife. It has always been my contention that no one knows that any given patient will have a normal labour till that labour is safely over. The following list shows the number of things that happened to our patients and that one assumes would happen to an equivalent number having their babies at home:

Number of patients delivered	961
Number admitted for toxaemia	116
Forceps	88
Caesarean sections	23
Hysterotomy at 28 weeks	1
Breech deliveries	21
Manual removal of placenta for P.P.H.	13
Blood transfusions	20
Induction of labour: medical	25
„ „ surgical	32
Eclampsias	3
Pathological laboratory investigations	315
Rh-negative patients discovered	5
X-ray examinations	136
Episiotomies	67
Total perineums sutured	267
General anaesthetics	161
Ante-natal attendances	7,759
Post-natal attendances	1,102

Number of patients attending post-natal clinic 808 out of the 961.

There was a very extensive use of analgesics: pethidine, sodium amytal, N_2O and air, etc. How does this list compare with one's knowledge of domiciliary practice as carried out among working-class patients and those attended by municipal midwives?

In 1943 in this city 1,535 confinements were attended by municipal midwives.

1. *Forceps Rate.*—This is very much reduced in domiciliary practice. Midwives tell me they rarely "need" to send for a doctor more than once or twice or 2 to 3 times a year in about 90 deliveries. I consider the forceps rate in the hospital too low. Many more women who are becoming tired might be helped out with low forceps. In my private practice every patient has a forceps delivery except in those cases where labour is so rapid that I simply do not arrive in time. The New York Lying-in Hospital had a forceps rate for 1942 of 571 in 3,151 deliveries. A few years ago I addressed a questionary to the doctors in this area on how they conducted a forceps delivery in a working-class patient's house; 60% replied and the vast majority did it single-handed with only the midwife to help them—i.e., to give the anaesthetic and hold up the legs, etc.; no sterile towels or gown. In this area neither the city or county health departments nor the hospitals provide a sterile outfit of towels and gowns for doctors doing a confinement.

2. *Analgesics.*—Practice varies, no doubt, but in this area very little is given by midwives, even bromide and chloral. Gas-and-air is now available, however, for any patient wishing it. It should be clearly understood that C.M.B. rules preclude any attempt at adequate sedation when only a midwife is in attendance, and even if a doctor is called in for that purpose it is doubtful if more than one dose would be prescribed, which is hardly adequate.

3. *Suturing of Perineums.*—It is, of course, notorious that midwives call for medical aid in a ridiculously low percentage of cases. Every obstetrician knows how far up the posterior vaginal wall a tear may extend without the external skin tear being very great. It simply means that many tears which should be sutured are left, with the consequent tendency to a rectocele. The common practice of simply putting stitches through the skin of the perineum as deeply as possible means an inefficiently sutured perineum. How many patients have an anaesthetic, local or general? I sutured a perineum for a midwife three weeks ago and she told me it was about the very first time she had ever seen anyone use any kind of anaesthetic. She is a municipal midwife of very long experience. It should be realized that a doctor is not always available at the time of the birth. This frequently means that the midwife leaves things ready and the doctor comes when he can and works single-handed. At the other end of the scale the New York Lying-in Hospital in 1942 had 1,876 episiotomies in 3,151 deliveries.

4. *Ante- and Post-natal Care.*—The vast majority of women who decide to have their babies at home attend a municipal ante-natal clinic. After all these years these are still being held in church rooms, disused shops, empty houses, etc., where patients undress behind a couple of screens and everything is makeshift. These clinics are commonly conducted by doctors who do no midwifery themselves and may have had no special training in obstetrics. The post-natal examination of these domiciliary patients presents difficulties because a great many will not go to a strange clinic or hospital to be examined by a new set of people.

What happens to the patients who ought to have a blood transfusion after a P.P.H.? No doubt the "bad ones" were sent to hospital, but the "flying squad" was called out only twice last year, both times to the county. Are the inductions of labour done for toxaemia? I feel only the severe cases go to hospital. Pyelitis and urinary infections are common; are all the urinary investigations done that are necessary? Are all the stillbirths and jaundiced babies investigated for the Rh factor? I doubt it. The City General Hospital ante-natal clinics do routine Wassermann tests on every patient, but these are not done at the municipal clinics. While making these frank criticisms of some aspects of the domiciliary service I would not withhold my share of praise of those men who, through the years, have attained great skill, nor of the midwives who work long hours at all times of the day and night in all weathers and who between them achieve very great results and bring care and help to the very poorest. I do maintain, however, that much more could be done for doctors, midwives, and patients.

The trend for more and more patients to enter hospital for their confinements is not a war phenomenon only, for the numbers have progressively risen year by year long before the war. It is not surprising. Maternity hospitals provide greater and more skilled ante-natal care by the men who are going to be responsible for the confinements, a higher standard of obstetrical judgment and technique. They provide relays of nurses, a doctor on the spot, senior consultants on the telephone, properly equipped theatres and labour wards, and plenty of analgesics; professional anaesthetists, plasma and blood on tap, oxygen and skilled resuscitation measures awaiting the baby; special care for premature infants, a visiting paediatrician, *x*-ray and laboratory facilities on the spot.

Everything is by no means perfect. I do not like the usual method of staffing hospitals by young house-surgeons and senior visiting consultants. Whole-time senior specialists resident in or near the hospital seem preferable. I am not enamoured of labour wards, where there may be several patients at different stages or of different temperaments, where the young and apprehensive is neighbour to someone noisy. Ante-natal clinics should not just be a frantic search for abnormalities. Talks could be given there to patients on some of the commoner things that go wrong in pregnancy; the importance of diet and vitamins, the coming baby, hygiene, suckling, etc. With the patients grouped together it is easier to prepare them psychologically for their coming labour, and there would be time for them to get to know the doctors who were going to be in charge, and time for them to feel at home in the hospital so that it would seem a friendly place. Progress will, I feel sure, be on these lines.—I am, etc.,

Leicester. C. L. SOMERVILLE.

Women in Labour

SIR,—There will always be pain in labour and tearing of the cervix and perineum so long as the unnatural position of lying down is enforced. The native woman squats, as did our ancestors, and so does the country woman when left to herself. Perhaps this is only seen now in remote parts of the British Isles as in the Islands and Highlands of Scotland. Peasants all over the Continent squat for defaecation and for parturition; hence little constipation and easy childbirth.

Reading Engelmann's *Posture and Practices During Labour* one realizes how recent is the now common practice of confinement on side or back. If you want to get a bullet out of a bottle you do not lay it on its side but turn it upside down, that the weight of the pellet may assist, not hinder, the evacuation. The difficulty attendant upon the use of the bed-pan is similar. In this position the pressure of the motion is exerted *unequally* on the circular wall of the bowel and hinders the process, because the normal reflexes are thrown out of gear. The same thing happens in a confinement when the patient is recumbent: the normal stimulus exerted by the weight of the on-coming head is applied on one side of the passages only;

unequal swelling of the parts results, which delays the advance of the child and increases the distress of the patient. Eventually the foetal head is forced past a circular opening now swollen out of shape and often blue with congestion—a condition most favourable to laceration.

My first squatting case in England was at Paddington L.C.C. Hospital. A primigravida of 42 belonging to a medical family, after doing ante-natal exercises designed to make her pelvic joints supple, was willing to forgo chloroform and be confined in the squatting position as an experiment. She talked to us during the proceeding, and said that as the head was passing the vulva (crowning) she felt no pain down there but only in the abdomen. (All went well, perineum intact; she made a good recovery and was able to nurse the child.) Presumably equal pressure numbs the parts exposed to it. But even more important than the actual position at the moment of delivery is the free movement allowed beforehand. This hastens matters and prevents the unnatural one-sided congestion so often seen that we become accustomed to it.

The idea that childbirth must always be so painful is held as an article of faith by many. In the East the psychology of this belief is thus explained. They say that all women are jealous of the child-bearing woman, and many expectant mothers there will tell you they do not go out for fear of ill-luck caused by envious eyes. Can this be the reason that almost every expectant mother in Britain seems to have friends like Job's comforters who discourse on the dangers and agonizing experiences that lie before her? For fear, so often subconscious, inhibits relaxation, and will turn a normal easy labour into a prolonged and difficult one.—I am, etc.,

London, N.W.11. KATHLEEN VAUGHAN.

Physiotherapists and Other Medical Auxiliaries

SIR,—I think it is time to ask whether the arrangements for training, qualification, national control, and social welfare for these important medical aides are entirely satisfactory. I ask this, not only from the point of view of the community as a whole, but on behalf of the interests of the societies concerned in particular.

Let us take the physiotherapists as an example of other societies, which all, incidentally, are tending to compete with the more fundamental sister service of nursing. The physiotherapists train in a variety of schools approved by the Chartered Society of Physiotherapy, which lays down the standard of training and arranges the examinations and standards of qualification. It conducts the examinations and confers the diploma upon successful candidates. The Society forms a register of approved physiotherapists. All of these functions are covered by the terms of its charter. In addition, it is a body which arranges for the postgraduate education of its members and for their social welfare, and takes part in political activity for the establishment of conditions of work and standards of pay.

In other words, the Chartered Society of Physiotherapy covers the functions which in medicine are those of the General Medical Council, the Universities and other examining bodies, the British Medical Association and other more social medical bodies, together with the Medical Defence Union. I have no reason to believe that the Chartered Society does not deal with all these functions satisfactorily, but the situation is an unusual one in the British social-political sphere and does not offer the safeguards which we usually find. It would, perhaps, be wrong to suggest that the various functions of such medical auxiliary societies should be split up into the compartments which we find in medicine as a whole; but some split-up, I do feel, is necessary. The standards of education, examining, and registration should be the function of one body, and perhaps should cover all medical auxiliaries. Conditions of work with social and political problems should be the function of a separate association. This was a problem which had to be faced by a similar body with which I am concerned—namely, that dealing with the training and examining of the special group of nurses employed in orthopaedics. The Joint Examining Board of the British Orthopaedic Association and Central Council for the Care of Cripples has made it perfectly clear that it will refuse to have anything to do with any aspect of the welfare of these people apart from standards of education, examining, and registration.

What has been said about physiotherapists applies also to such sister bodies as those concerned with occupational therapy, radiography, etc.—I am, etc.,

Exeter. NORMAN CAPENER.

Press Publicity

SIR,—Every one of Dr. Leak's colleagues will sympathize with his annoyance at the publicity which has been accorded to his recent contribution on the subject of impending dissolution, and none will require his assurance that such publicity was both unexpected and unwanted. But as in his letter to your columns (Sept. 15, p. 368) he raises the question of newspaper reporting in general, it may not be inappropriate to attempt a dispassionate examination.

Dr. Leak was challenged, so to speak, by a reporter with the charge that he was the first doctor in this country to put into print that he practised euthanasia. Presumably Dr. Leak was concerned not so much with renouncing a claim to a perhaps undesirable priority as in repudiating the practice of euthanasia as this term is understood. He says he found it no easy job to make the reporter understand the difference between *that*, and the action he undertook in the interest of his suffering friend. With all respect for Dr. Leak's sincerity and his dialectic powers, I should have thought he was attempting to do something not only difficult but impossible. For although the extraction of a sentence from its context may on occasion lead to distortion and even complete misinterpretation, the statement that he administered an intravenous injection to the patient "because he felt justified in putting him out of his misery" can hardly be open to alternative explanations. That Dr. Leak, in fact, failed to implement his intention does not invalidate that intention, and it is not surprising to find the reporter accepting this conclusion and utilizing it for presentation to a public avid for such information. Need I add that I am not criticizing Dr. Leak's principles nor considering the subject of euthanasia in general, whether ethically, legally, or otherwise?

Perhaps our profession does not adequately appreciate that the doctor and all his doings are "news," attractive material for the provision in the lay press not of instruction but of entertainment. It is the *métier* of a journalist of a certain section of the Press to select outstanding features *ad captandum vulgus*. I do not suggest that he will deliberately misrepresent, but it is the dramatic, the spectacular, the sensational that he is seeking, and with scientific accuracy he has no concern, more especially as in that respect he has no responsibility. No wonder that the innocent contributor to a professional journal is on occasion amazed and indeed appalled by the startling repercussion of something that has been extracted and cleverly presented, perhaps with pretentious head-lines. It is best for us to recognize the inevitable. I do not think that anything can avert such occurrences. Dr. Leak himself expresses the opinion that we should help to educate the public in some of the facts of health and medical practice. A fine ideal; but as a humble amateur I cannot but fear that we can never compete successfully with the professional whose very livelihood depends upon diversion and not instruction.

I doubt if any necessary or useful purpose is served by the "disclaimer" which is published by the doctor who has incurred publicity whether through some innocent inveiglement or quite gratuitously. To all who know him his protestation is quite superfluous, and to any who are uncharitable enough to suppose that publicity was sought or encouraged, the disclaimer may provide additional evidence in support of their belief.—I am, etc.,

London, W.1. ADOLPHE ABRAHAMS.

SIR,—In his letter on press publicity Dr. W. N. Leak speaks of the good will which he has encountered in the newspaper world and calls for greater co-operation between his profession and the journalist profession. As one who has for ten years been a scientific journalist and who has always included medicine within the category of science, I would like to make a plea for closer co-operation than exists. There are, I believe, three reasons why the medical profession should welcome publicity in the ordinary newspapers:

1. Without informed news about medical matters the only medical information received by the common reader is con-

tained in advertisements of patent remedies—at best a one-sided, probably lop-sided, education in the art of healing.

2. Without a clear, though doubtless elementary, knowledge of the body in health and disease and of the rationale of treating it, your patients can give you no help in your task and you cannot rise in intellectual status above the medicine man of a primitive community.

3. In a democratic community you are rightly at the mercy of your patients as a voting body. Through no fault of your own you cannot claim as yet 100% success in your art, and it is well that the general public should realize that it suffers from acts of God far more often than from medical incompetence.

I would add that the voluntary hospitals seem to me much to blame for their neglect of an obvious weapon in their hands. On every day of the year something is happening in some hospital which could be the basis of an article which would interest the public and yet be perfectly accurate and in medical good taste. It is only when an outstanding event—such as the discovery of penicillin—is allowed to "break" that we laymen get any idea of the work being done for us.

What is needed from your profession is the appointing by hospitals, by research laboratories, and by medical learned societies, of officials with publicity sense to whom the lay press can refer for information. So far as the newspapers are concerned, they must appoint men on their staffs with a scientific education, authorized to control all news items and other articles having to do with scientific or medical matters (not least they must be able to control the head-line writers). Such journalists must work out a code of ethics for themselves, and I suggest that the following points are among those to be included: (1) Articles on medical research and discoveries should not appear in the lay press before they have authoritatively appeared in the technical press. (2) "Feature" articles written by journalists who are not medical men should be submitted to a referee for "vetting" as to accuracy. (3) Personal publicity should in most cases be avoided. (4) The encouragement of false hopes of cure and the giving of a false perspective by wrong emphasis must be avoided. The social rather than individual implications are those that should be stressed.

What is needed from the medical profession is a habit of giving generous publicity in a steady day-to-day stream. This is the only way to avoid the "head-line" technique too common to-day. Visualize what happens in a Fleet Street office: an enterprising reporter with only one qualification, "news sense," turns over the pages of the *B.M.J.* or the *Lancet* and notes that somebody's prostate has been treated with a hormone preparation. He rings up a few doctors, who treat him with alarmed contempt; falls back on his own ingenuity and a family medical guide, and the results come out as "cancer cure found." The way to stop this is for the medical profession to develop "news sense" on their part and to co-operate with the well-educated men that Fleet Street can provide.—I am, etc.,

Burwash, Sussex. JOHN LANGDON-DAVIES.

Doctors and the Social Trend

SIR,—I always find Dr. Shackleton Bailey obscure. Such pontifications as "Whereas retention of private practice might have been tolerated as an anachronism best left to die a natural death, it might now be hailed as a certain indication that the Government intended to cater for sectional interests generally and in a way that would perpetuate the reservation of a super-service in life's essentials for the benefit of a small and wealthier minority" (Aug. 7, 1943, p. 181) are too much for my simple mind. I don't see what he is getting at. But to the plain man it would seem to be fairly obvious that amid the mass of verbiage there runs, and has always run, the single thread of a confirmed and convinced acquiescence to lay political pressure, or "defeatism" as Drs. Pemberton, Harrower, and Henderson call it (Sept. 1, 1945, pp. 302 and 303).

"The electorate," as typified by the man in the street, has very little interest in the adumbrated regimentation of the doctors, and a patient of mine crystallized the mass of opinion that I have listened to for the last year or so when he said, "Well, doctor, *we* don't know anything about it. It's up to you, and if you doctors have anything to object to you ought to up and say so. *We* can't help you."

On Feb. 27, 1943, p. 266, Dr. Bailey offers "the whole resources of modern medicine to 100% of the population," and invites us to "see to it that every one in that profession is adequately paid for his services." But the 100% issue was flatly turned down last December by the A.R.M., at which I was present, by 147 votes to 88; and it is painfully obvious to anyone like myself who has for forty years been closely watching the "social trend" as it affects medicine that *no* Government, however able, patriotic, and democratic, will *ever* offer the doctors adequate payment for anything they do for them; witness the miserable fees paid for N.H.I., Factory Act examinations, and Service men and women sick on leave. In refutation of this Dr. Bailey produces the following astonishing argument (Oct. 2, 1943, p. 436): "I agree with Dr. Gaskell that remuneration under the Factory and N.H.I. Acts is very low, but I do not think that this is a sample of Governmental valuation of our professional services." In Heaven's name, then, what is it a sample of? He goes on to say, "In my view it represents the valuation we have set upon ourselves by lack of corporate idealism and the debasement of our members to the level of competitive business units." If this means anything, it means that we have in the past and in certain cases been slavishly following the very footsteps of surrender which Dr. Bailey is now inviting us to tread, in response to his "world force," "electorate," and "social trend." On Sept. 4, 1943, p. 311, he takes Dr. Leak to task for saying that "the doctor's duty is to speak and act as he thinks right, without fear or favour," opining that he "fails to see how this ideal can be achieved in any system where the doctor's remuneration is directly proportional to the extent to which he pleases each individual patient." But here I, and I believe the vast majority of my colleagues, are definitely "on the side of the angels"—i.e., Dr. Leak.

Either because we have not the time, or are too lazy, or too much interested in our job, most of us cannot be bothered to be always, or at any time, laying ourselves out in sycophantic manner to "please" our patients in any other way than by being pleasant to them and doing our best to cure them of their diseases, which is after all what they want. On Feb. 27, 1943, p. 266, Dr. Bailey says: "If the medical profession offers every citizen full medical services under the 100% proposal and at the same time announces that it is prepared to accept a higher rate of payment by private arrangement *for the same services* [my italics] the public must conclude either that we think it worth while to exploit the type of person who will pay £2 for what he can get for £1 (but if he were paying £1 to his doctor he presumably would not be in the 100% free scheme), "or else that we are conniving at the suggestion that patients treated under the 100% proposal are not really enjoying the whole resources of modern medicine at all." What dreadful nonsense! I am sure Dr. Bailey does not believe it. Imagine saying to a patient, "Here is a prescription for a bottle of medicine which you can get made up for nothing under the N.H.S. at a chemist, but if you like you can take it down to my own private dispenser and get it made up there, in which case my fee will be 7s. 6d., and the medicine will do you much more good!" Neither Dr. Bailey nor anybody else is such a humbug as that. It is obvious that, even looking at the matter from the most mercenary and commercial point of view, it is to our interest to get our N.H.I. patients well and off our hands as quickly as possible, and in order to do this we give them the best possible treatment.

As to his strenuous objections to any patient "contracting out" of any National Health Service if he so wishes, suppose that the furniture dealers and butchers were foolish and weak enough to allow themselves to be paid salaries and turned into Government Departments. I am a member of the N.F.&B. Service, and I want a new armchair and a leg of mutton. If I do not quite like the look of either of the two commodities offered me under the "take-it-or-leave-it" rules of the N.F.&B.S., why, supposing that I have saved up the necessary money, should I not have the chance of dealing with a furniture shop and a butcher who are not members of the service, and who have a "vested interest" in selling me an armchair which is a joy to sit in and a leg of mutton which looks to me very good?

"The medical profession can no longer defy a force that has swept Mr. Churchill aside" (Aug. 18, 1945, p. 235). But the swing-over to Labour and the temporary eclipse of the greatest leader we have ever had had nothing whatever to do with any feeling for or against the medical profession or medical services. Dr. Bailey might just as well say: "Now that the Japs have given in and the Americans have become so powerful we really must put our house in order and give in all round. Let no one think he can obstruct the course of events."

It is quite on the cards, however, that the new Ministry will see the light, and will realize that tinkering with the doctors now will not reduce the incidence of sickness and ill-health by one iota, and that their true mission is to remove the causes of disease, malnutrition, and national debility not by salaries and bottles of medicine, but by improving housing, environment, conditions of work, and facilities for outdoor recreation.—I am, etc.,

Stowmarket, Suffolk. H. S. GASKELL.

Humanitarianism and the European Situation

SIR,—The recent reports in the press that graves are already in preparation for those who are going to die of starvation during the coming winter in Europe must have brought some realization, even in a world immunized against horror, of the ghastly aftermath of war. Nor to a great many of us does the fact that the greater proportion of those already doomed are our recent enemies alter the tragedy and fundamental "wrongness" of the situation. For whatever the causes and wherever the responsibility lies for this economic and social chaos the result of helplessly watching the slow death of friends and relations can only be the breeding of hate in those who survive. There lies the danger, for there is already enough hate in the world, and in it lies one of the many causes of wars.

I am well aware that the results of war in Europe are inescapable, and that in a world where food and transport have been decreased and disorganized death from starvation is inevitable. I am equally well aware that a great deal is being done both by the United Nations (U.N.R.R.A., etc.) and by individual and voluntary organizations throughout the world to mitigate the disaster. But I believe there is another method which could be applied which not only would save at least some lives, be it only a small proportion, but would also make a great and very real contribution towards world peace. It would involve personal sacrifice, difficulties, and perhaps even hardship on the part of many families, but within the few hours that I have been thinking and talking of this idea four families among my immediate circle have indicated their willingness to make the attempt.

Is it not possible for a considerable number of families to undertake the care of one European child, under the age of, say, 10, for a period of one year? I am quite convinced that we could find without difficulty at least ten thousand families willing to do this in Great Britain, and furthermore to accept this responsibility without an increase in the present ration scale. This could be extended to other countries, who, I am sure, would do likewise—Canada, South Africa, America, Eire, Sweden would all accept a quota. "Quota" is not perhaps the correct word, since the first essential for such a plan to be successful would be for the homes to be offered with absolute certainty before any attempt was made to find the children to go to those homes. Difficulties would be great—language, transport, opposition from those we wish to help even—but they are not insurmountable. Apart from world shortage, the greatest single difficulty in the European food situation is the transport and distribution of food in Europe. That problem is relieved by the suggested solution of taking the child to the food instead of the food to the child. There is ample food in this country alone, low as the fat and protein ration already is, to feed at least 100,000 more children without issuing any more rations than are issued at present and without any real hardship to anyone. I know that to be true from both my knowledge as a doctor and my experience as a prisoner of war. The transport difficulty could possibly be overcome by the use of heavy bombers for transporting the children; it would be a great thought that the use of one of the instruments of liberation was being extended to the salvation of Europe.

If such a plan can be put into operation the long-term effects are incalculable in their potentiality for good. It would be a real step towards fostering that internationalism which so many of us realize is the only hope of survival and progress of the human race. I trust, too, that German children would not be excluded from the plan; indeed they must be included; for apart from all humanitarian ideals the educational value of even 1,000 German children spending a year in British homes would be greater than twenty years of attempted control of education in Germany.

I am writing this letter to the daily press and to the *British Medical Journal* in the hope that someone will investigate the possibility of putting this idea on a practical basis. I am unable to do this myself as I am leaving for the Continent within the next few days to take up work with U.N.R.R.A.—I am, etc.,

ERIC TOWNSEND,
Late Lieut.-Col., R.A.M.C.;
Skipton. Ex-P.o.W., Oflag 79, Stalag Luft 3, etc.

Obituary

Burnley loses a senior practitioner by the death on Sept. 2 of Dr. JAMES HAWORTH, who had been in practice there for over forty years. Dr. Haworth, who was a native of Bacup, was educated at Manchester Grammar School and Edinburgh University, graduating M.B., Ch.B. in 1898. After holding resident appointments at Oldham, Sunderland, Lancaster, and other places, he entered general practice in Burnley in 1902. During a long period of service his activities were numerous, but his anaesthetic work was that nearest his heart. At the time of his death he was senior anaesthetist to Burnley Victoria Hospital and anaesthetist to Burnley Municipal Hospital; from 1916 to 1919 he had been anaesthetist to the Military Hospital at Whalley. Though latterly not active in the B.M.A., he had at one time been secretary of the local Division. James Haworth was not one of those practitioners who "do anaesthetics"; he was a student of his subject. He paid particular attention to the American literature and became a Fellow of the American-sponsored International College of Anaesthetists. Thoroughly expert in the older methods, he modified or discarded these when convinced by personal trial of the advantages of a newer procedure. He welcomed progress, but viewed change in that canny manner that helps so much in its correct assessment. He leaves a widow, a daughter, and two sons who were both abroad with the Forces. He was one of the many of our profession who, carrying on till the end of the war, have not survived to welcome home their sons and successors.—A. D.

Dr. RONALD CATHCART OZANNE, who died after a short illness on Sept. 14, aged 58, was well known and much liked at Harrogate, where he had been honorary physician to the Harrogate and District General Hospital for many years, and also honorary anaesthetist. From Haileybury College he went to Oxford, and thence to Guy's Hospital after gaining first-class final honours in the School of Physiology in 1909. He graduated M.A., M.B., B.Ch. in 1913. During the war of 1914–18 he served in the R.A.M.C. with the temporary rank of major and was surgical specialist at No. 22 Casualty Clearing Station. On returning to civil life he settled at Harrogate, where his late father had been in practice. Dr. R. C. Ozanne joined the B.M.A. in 1919, and was an active member of the Harrogate Medical Society. He was for some time medical officer for Dr. Barnardo's Homes in Harrogate and at Hollins Hall. The funeral on Sept. 18 was attended by many medical colleagues and representatives of the Harrogate General Hospital and other institutions.

Mr. A. Ernest Sawday writes to supplement the notice published on Sept. 1: I should like to pay a tribute to the memory of Dr. ALEXANDER BROWN, whom I met only once, though I had previously spoken to him on the telephone and corresponded with him a few times. Some weeks before his death I had occasion to visit a patient with him. I picked him up at Bartholomew Road and took him to the patient's house. I found him a very spruce, alert man. He took the greatest pains over the patient, who was suffering from malignant disease. Later he told the patient's wife (to cheer her up) that he himself had had an operation for similar trouble. As we drove away he informed me in the most cheerful manner that he had secondary deposits in his liver. He said that he realized that he could do nothing about it and that he did not propose to let it worry him and that he hoped to go on working. I am left with the memory of a very fine doctor, a great gentleman, and a very brave man.

A dispatch from the Canberra correspondent of the *Times* states that information has been received from trustworthy Chinese and local sources, and confirmed by the Japanese, to the effect that, on the night after the Americans' first bombing of the island of Nauru, the Japanese executed, among others, the Administrator of Nauru, and the Government medical officer, Dr. B. H. Quin, and his assistant. Bernard Haselden Quin was born in 1894 and graduated M.B., B.S. of the University of Melbourne in 1920. In 1920–1 he was assistant medical officer at Nauru, and on Ocean Island. After practising in Victoria he returned to Nauru as second medical officer in 1935, and was promoted to the senior post five years ago.

The following well-known medical men have died abroad: Prof. Antonin Gosset, an eminent French surgeon, Fellow of the Académie de Science, Académie de Médecine, and Académie de Chirurgie; Dr. Fernand Arloing, professor of bacteriology at Lyons University and an authority on tuberculosis; Prof. Karl Frick, director of the Röntgen department of the Charité Hospital, Berlin; and Geheimrat Prof. Emil Kruckmann, emeritus professor of ophthalmology at Berlin University, aged 78.

The Services

Temp. Surg. Lieut. K. W. Dodd, R.N.V.R., has been awarded the D.S.C., for gallantry, skill, and devotion to duty while serving in one of H.M. ships on the East Indies Station, in operations which brought about the destruction of a Japanese heavy cruiser of the Nachi class and the probable destruction of a Japanese destroyer.

Col. (Acting) G. M. Warrack, D.S.O., R.A.M.C., has been appointed O.B.E. (Military Division) and Capt. J. Lawson, R.A.M.C. has been mentioned in dispatches in recognition of gallant and distinguished services in the field.

Lieut.-Col. (Temp.) A. T. Marrable, R.A.M.C., has been awarded the D.S.O., and Lieut.-Col. (Temp.) W. C. Alford, O.B.E., Capts. C. C. M. James and V. D. R. Martin, and Capt. (Temp.) G. F. H. Drayson, R.A.M.C. (since killed in action), have been mentioned in dispatches in recognition of gallant and distinguished services at Arnhem.

Major (Temp.) F. I. Evans, R.A.M.C., and Capt. E. B. Naug, I.A.M.C., have been awarded the M.C., and Capt. J. Jacobs and Lieut. F. S. Stubbs, R.A.M.C., and Capt. J. P. Chesney, R.C.A.M.C., have been mentioned in dispatches in recognition of gallant and distinguished services in Burma.

Freed in the Far East.—Surg. Cmdr. R. W. H. Tincker, R.N.V.R. Majors G. O. Gauld, R. P. Graves, and P. E. F. Routley; Capts. G. M. Davies, J. A. Falk, H. D. T. Gawn, J. Hendry, J. D. Lodge, and J. Richardson, R.A.M.C. Lieut.-Col. F. H. A. L. Davidson. Major J. W. D. Goodall, and Capt. A. W. B. Strahan, I.M.S.

Repatriated.—Col. J. T. Simson, A.M.S., and Major W. J. E. Phillips, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Died.—Surg. Lieut. Ian Gordon Forbes, R.N.V.R.

Wounded.—War Subs. Capts. A. J. Briggs, D. L. Harbinson, and L. G. J. Pitt-Payne, R.A.M.C.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following lectures will be delivered at the College (Lincoln's Inn Fields, W.C.) at 5 p.m. each day: Thursday, Oct. 4, Imperial Cancer Research Fund Lecture by Dr. Leslie Foulds, "Observation and Theory in Cancer Research." Thursday, Oct. 11, Lister Memorial Lecture, by Sir Howard Florey, "The Use of Micro-organisms for Therapeutic Purposes." Erasmus Wilson Demonstrations: Monday, Oct. 22, Mr. R. Davies-Colley, Specimens illustrating cysts and innocent tumours of the breast; Wednesday, Oct. 24, Mr. Davies-Colley, Specimens illustrating malignant tumours of the breast; Thursday, Oct. 25, Mr. L. E. C. Norbury, Certain conditions of the kidney, illustrated by specimens and lantern slides. Thursday, Nov. 1, Thomas Vicary Lecture by Sir Arthur MacNalty, "The Renaissance: its Influence on English Medicine, Surgery, and Public Health." Thursday, Nov. 8, Bradshaw Lecture by Mr. C. Max Page, "A Survey of Fracture Treatment."

Medical News

The R.A.F. has announced that medical officers in age-and-service groups 15 to 20 inclusive will be released in November and December.

The Medical Department of the Navy has stated that Naval medical officers in Groups 1 to 7 who have not volunteered for further service will either be released or be on their way home for release by the end of October, and a start will be made on Groups 8 to 15. The Admiralty is awaiting information as to the number of medical officers who wish to remain in the Service before making a further announcement; the aim is to release all groups up to 15 by the end of the year.

The annual luncheon of the Society of Medical Officers of Health was held at the Holborn Restaurant, London, on Sept. 21, with the president, Prof. R. M. F. Picken, in the chair. The principal guest was the Right Hon. Aneurin Bevan, Minister of Health. There were only two speeches—one by the Minister proposing the toast of "The Society," and the President's reply. Mr. Bevan's informal address (which by his wish is not reported) touched on five matters of major importance to public health officers and made a very good impression. He did not discuss the Government's plans for a National Medical Service. Prof. Picken thanked the Minister for his felicitous words and welcomed the official guests, beginning with the Parliamentary Secretary to the Ministry and Sir John Maude, the Permanent Secretary, who, to his regret, was attending for the last time as holder of that office; also representatives of associations of local authorities, the Mayor of Holborn, and officers of the Royal Sanitary Institute. The professional guests whom he saluted were the Presidents of the three Royal Colleges, the President, Chairman of Council, and Secretary of the British Medical Association, the President of the General Medical Council, and the editors of the *Lancet*, the *British Medical Journal*, and the *Medical Officer*. Speaking briefly on the origin of the Society of Medical Officers of Health and the bigger and bigger part it had taken in the promotion of progress, he paid tribute to the early influence upon himself of his teachers at Glasgow—Samson Gemmell and William Macewen—for their emphasis on the importance of social and environmental conditions as factors in the causation of disease. He said that clinical and preventive medicine spoke the same language, though perhaps with slightly differing accents. The success of a medical service would depend on the quality of its men and women, and it must therefore attract the best brains. Lastly, Prof. Picken assured the Minister that his efforts to safeguard the milk supply would have the wholehearted support of the profession in overcoming obstruction by vested interests.

Dr. J. R. Rees, F.R.C.P., medical director of the Tavistock Clinic, will give the opening sessional address at the Welsh National School of Medicine, Cardiff, on Tuesday, Oct. 2.

The Ex-Services Welfare Society (Temple Chambers, Temple Avenue, London, E.C.4) has arranged a medical conference to be held in the Hall of the Royal College of Physicians of Edinburgh on Friday, Oct. 5, beginning at 10.30 a.m., under the chairmanship of Prof. Henderson.

Sir Robert Hutchison will preside at the prize distribution and conversazione to be held at the Royal Dental Hospital of London School of Dental Surgery on Saturday, Oct. 6, at 3 p.m.

Dr. Kate Friedlander will give a lecture on "Mental Ill-health: The Problem of Its Prevention" before a meeting of the Whipps Cross Hospital Medical Society at the hospital on Friday, Oct. 5, at 8.30 p.m.

The following members of the medical profession have been released from internment in Japanese hands: Dr. William Ainslie, Dr. Harry Allan, Dr. Richard Thomas Bonfield Green, Dr. Robert Stevenson Hardie, Dr. Frederick Viel Jacques, Dr. Robert Barr MacGregor, Dr. Nicol Campbell Macleod, Dr. Robert Allan Macnab, Dr. David Morrison McSwan, Prof. Eric Cameron Mekie, F.R.C.S.Ed., Dr. Gordon Alexander Ryrie, and Dr. Henry Scrimgeour.

The Right Hon. Walter Elliot, F.R.C.P., F.R.S., has been elected President of the Royal Institute of Public Health and Hygiene in succession to the late Sir Stanley Woodwark.

Dr. Carl Gustav Jung, professor of psychiatry and psychology at Zürich, celebrated his 70th birthday on July 26.

Dr. C. Ainsworth Mitchell retires from the editorship of the *Analyst* on Sept. 30, after twenty-five years in that position. He was secretary of the Society of Public Analysts and Other Analytical Chemists from 1925 to 1937.

The Empire Rheumatism Council has now permanent offices at Tavistock House (Entrance B), B.M.A. House, Tavistock Square, London, W.C.1. Correspondence is invited from all interested in the campaign against rheumatism. Donations and bequests are welcomed.

From Paris, where the Academy of Medicine in plenary session made him an honorary member, Sir Alexander Fleming went on to Italy to visit medical establishments of the R.A.F., and the University of Rome took the opportunity to confer on him an honorary degree. He was received by General de Gaulle in Paris, and in Rome the Pope gave him an audience.

The Public Health Committee of the Manchester City Council has appointed a deputation to the Ministry of Health to call attention to the serious position which has arisen in the municipal hospitals in the city as a result of the shortage of staff. Unless additional help is forthcoming, many beds will cease to be used in the near future.

The King, on the recommendation of the Secretary of State for Scotland, has approved the appointment of Brigadier Thomas Ferguson Rodger, M.B., Ch.B., M.R.C.P., D.P.M., to be a Medical Commissioner of the General Board of Control for Scotland in room of Dr. Aidan G. W. Thomson, who has retired. Brigadier Rodger is at present consulting psychiatrist to the India Command, and was formerly senior assistant superintendent, Glasgow Royal Asylum, Gartnavel.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* there were respectively 131 and 46 more cases of scarlet fever and diphtheria than last week, but 313 and 67 of measles and whooping-cough. In London the incidence of scarlet fever rose by 27. The largest local outbreak of diphtheria was in Oxford C.B., 10 notifications. In Lancashire the incidence has increased by 50% in the last two weeks, and the 103 cases were a quarter of the total notifications of the country; 38 were recorded in Liverpool C.B. There were 26 fewer notifications of whooping-cough in Lincolnshire. The incidence of measles continues to go down; it has fallen more slowly in the east and south-east (excluding London) than in the rest of the country, these areas having slightly more than one-third of the total notifications.

Dysentery notifications were 8 fewer than last week. The chief centres of infection were Lancashire 40, London 39, Warwickshire 25 (Birmingham C.B. 16), Lincolnshire 15, Yorks West Riding 15, Glamorganshire 15, Middlesex 13, Suffolk 13, Essex 12, Bedfordshire 11.

In *Scotland* scarlet fever notifications went up by 23; the incidence of this disease has risen by 70% during the past four weeks. Twenty-one fewer cases of dysentery were recorded—the first decrease for four weeks; the largest returns were those of Glasgow 43, and Edinburgh 26.

In *Eire* notifications of diphtheria, which rose by 42 cases the previous week, fell by 46 to the level prevailing during August. The notifications of diarrhoea and enteritis were 40 fewer than last week, but the incidence is still very high, 80 cases being recorded in Dublin C.B. A small outbreak of infantile paralysis, involving 7 persons, with one death, has been reported from the Foxrock district of Co. Dublin.

In *Northern Ireland* diphtheria notifications increased from 15 to 23, the largest total of recent months.

The Health of Gloucestershire

The County Medical Officer, reviewing the health of the county during 1944, drew the disquieting conclusion that the health of the people of Gloucestershire has deteriorated and is progressively getting worse. This statement was based on the rise in infant mortality and in tuberculosis and general death rates. Infant mortality increased from 40 in 1943 to 46 in 1944. The number of cases of tuberculosis notified during the year was 533, compared with 386 in the preceding year. The C.M.O. stated that, while it was dangerous to draw conclusions from general impressions, the information obtained from visits to homes, schools, and institutions suggested a general increase in minor ill-health and in major conditions. The most urgent need was an increased and more varied diet, with more protective foods.

Week Ending September 15

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,381, whooping-cough 1,159, diphtheria 495, measles 551, cerebrospinal fever 39, acute poliomyelitis 31, dysentery 292, paratyphoid 15, typhoid 17.

No. 36

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 8.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1945					1944 (Corresponding Week)

ANY QUESTIONS?

Lanette Wax SX

Q.—*One frequently sees lanette wax SX used nowadays as the base for various emulsifying creams. I should be grateful for information regarding this substance's properties; and also regarding the meaning of the letters SX.*

A.—Lanette wax SX is a somewhat variable mixture of the partially sulphated or phosphated higher fatty alcohols, chiefly hexadecyl and octadecyl alcohols. The product originally on the market was sulphated, but it was later found that a phosphated product was superior. Limitation of supplies during the war necessitated, however, a reversion to the sulphated product, and it is this that is on the market at present. We expect the phosphated product to reappear when supplies and material again become available.

It is a white, or creamy-white, wax-like substance, with a melting-point of about 50° C., the sulphated product being somewhat darker in colour, softer and more unctuous to the touch than the phosphated. It readily emulsifies with water, and is used in the preparation of the oil-in-water type of emulsion in the manufacture of cosmetics, toilet articles, and pharmaceutical creams, ointments, etc. The SX was used to indicate an approximate 10% sulphation of the original alcohols and serves to distinguish the sulphated or phosphated product from lanette wax itself, which is simply the mixed alcohols.

Low Blood Pressure

Q.—*Could you suggest a routine line of treatment for a man, aged 40, suffering from low blood pressure—fallen from 100/70 to 90/60 in the last three months? A three-weeks holiday has had no beneficial effect. Electrocardiograms show some myocardial degeneration. There is no evidence of Addison's disease or anaemia, and no loss of weight. He has been taking vitamin B and other vitamins, ephedrine and methedrine tablets.*

A.—It would appear that this patient needs further prolonged rest. Probably such a fall in blood pressure is not in itself important but an indication of defective vasomotor tone. On the other hand, the hint that myocardial degeneration is present, as shown in the electrocardiogram, might be another factor. In such a case as this full doses of strychnine might be worth while.

In Addison's disease the external appearances are sometimes rather late in developing, and investigation of the blood chemistry might be done with advantage.

Whoop after Vaccine

Q.—*I have recently given two injections of prophylactic whooping-cough vaccine—one six weeks ago, the second two weeks ago—to a boy of 3 years. There is no whooping-cough in this area, and I can discover no possible contact, but the child has been whooping merrily for the last four days. Is it possible to cause signs and symptoms of whooping-cough with vaccine, and if so how long will they persist?*

A.—In a recent article Sako and colleagues (*J. Amer. med. Ass.*, 1945, **127**, 379) state that "following inoculation an occasional infant developed a paroxysmal pertussis-like cough which disappeared in a short time." It is not stated how soon after inoculation the paroxysmal cough appeared, and in the present instance onset two weeks after the second dose seems rather a long interval for the cough to be ascribed to the vaccine. If, however, there is no whooping-cough in the district and the child has not been exposed to the risk of infection from an outside source, a post-inoculation reaction seems the likeliest diagnosis. If the characteristic cough persists for more than a week, pertussis would have to be excluded by, for example, a white-cell and differential count. Enlarged tonsils and adenoids or sinusitis may also cause a persistent type of cough in a child.

B. proteus Infection of Prostate

Q.—*Is there any cure for prostatic infection by B. proteus?*

A.—Cure lies in the first instance in careful examination of the urethral aspect of the prostate with a posterior urethroscope. This will almost certainly reveal dilated ducts, with septic material exuding on pressure from the rectum; for after this long time it is most unlikely that the acini are all normal. In all probability many of them are now lined not by normal mucosa but by granulation tissue. The next step, when this is established, is to lay the ducts open by incision with a diathermy knife, or to resect part of the gland with a prostatic resectoscope. This reply is on the assumption that the investigations are first carefully carried out, and, secondly, that they reveal the abnormalities alluded to.

Pain in Ulnar Nerve

Q.—*Since December, 1943, a woman aged 34 has had pain and tenderness of the left ulnar nerve, which came on without known cause. She has had intensive vitamin therapy and physiotherapy, and also local injections of novocain, the latter with transient relief only. X-ray examination of elbow and shoulder was negative, and the scalenus syndrome ruled out. She has been immobilized in plaster-of-Paris for six weeks, without relief.*

A.—The cause is a local one and does not call for general treatment. The two most likely possibilities are a local tumour—neuroma or neurofibroma—or local irritation in the ulnar groove. The second condition is the result of repeated trauma in a shallow groove, often associated with an increased carrying angle of the elbow. In either case treatment depends on the degree of damage which has been done to the nerve. If there is evidence of wasting of the intrinsic muscles of the hand it may be advisable to explore the nerve with a view to excising a neuroma or transplanting the nerve to the front of the internal condyle, depending upon the cause.

Cancer and the Blood

Q.—*What changes are to be found in the blood of patients suffering from cancer, apart from a secondary anaemia?*

A.—A detailed analysis of changes in the blood in cancer has been made by O. C. Gruner, whose book, *A Study of the Blood in Cancer* (London, H. K. Lewis), was reviewed in the *Journal* of Aug. 8, 1942. This book deals with macroscopical and microscopical changes in the cells and plasma. Many serological tests have been introduced, and a number of these were reviewed and rejected by Panton in the *Lancet* of April 3, 1937.

Nearly all serious students of the subject have concluded with Ewing that the various reactions in the blood in cancer are non-specific and the diagnostic reactions are equally so. The search for a universal test for cancer is gradually being replaced by the discovery of specific properties belonging to individual forms of tumours, such as the phosphatase reaction in prostatic carcinoma. The secondary anaemia of cancer is an anaemia with no special characteristics to distinguish it from other anaemias resulting from haemorrhage and toxaemia. If the tumour metastasizes to the bone-marrow a leuco-erythroblastic blood picture may occur, but this is also met with in a variety of conditions besides cancer.

Acidaemia in Gas Gangrene

Q.—*(1) In Sir Almroth Wright's book, "The Pathology and Treatment of War Wounds," a series of experiments is recorded "showing that the growth of the bacillus of Welch in the blood fluids is promoted by the addition of acid." In the latest edition of Illingworth and Dick's "Surgical Pathology" there occurs this statement: "It is interesting to note that the acid produced by saccharolytic organisms such as Cl. welchii tends to inhibit the growth of the organisms in vitro, but in wounds the acid is partly lost in the profuse discharge and partly neutralized by the inflammatory exudate, by calcium salts, and by the alkaline products of the proteolytic organisms." Sir A. E. Wright deduces, from his findings of a constant acidaemia in patients with gas gangrene, the usefulness of intravenous sodium bicarbonate and of sodium lactate by mouth. This method does not seem to be recommended at present. I should be glad to have the difficulty cleared up.*

A.—Insofar as these statements are contradictory, the truth lies in the former. The second appears to overlook the difference between growth in an artificial medium containing a large quantity of fermentable sugar, in which, indeed, saccharolytic bacteria may produce so much acid as to prevent further growth or even to ensure their own destruction, and growth in tissues where the available sugar is considerably less in amount. There is in fact no need to assume the operation of any of the factors mentioned—and the third, the presence of proteolytic organisms, is often absent in true gas gangrene—to account for the continued growth of *Cl. welchii* in the tissues. There is an acidaemia in gas gangrene, and this is an aspect of the disease which deserves more attention than it has received. To what extent correction of the acidaemia could contribute to recovery is uncertain, but it would perhaps be unduly optimistic to regard the administration of alkali as anything more than an adjuvant to chemotherapy and antitoxin treatment.

Dysmenorrhoea in Middle Age

Q.—*May I have advice on the treatment of dysmenorrhoea in a woman aged 43 years? She is somewhat highly strung and inclined to be introspective.*

A.—Is the woman married or single, parous or otherwise? Where is the pain felt? What is its character? And does it occur before, during, or after menstruation? At what age did the dysmenorrhoea begin? Without knowledge on points such as these, comment on the case is not likely to be very helpful. Dysmenorrhoea of the types common in girls and young women is unusual at this age, and although the symptom may appear to be related to the patient's nervous disposition, local organic disease—especially endometrioma or pelvic infection—should be excluded before any decision is made as to treatment. The presence of some such local condition is even more likely if the dysmenorrhoea has *begun* late in life.

Infection of Skin of Hands

Q.—*A married woman suddenly developed reddening and burning on the right hand, across the palm at the bases of the fingers and also up the sides of the fingers and thumb. Later some desquamation occurred, together with cracks, but no bleeding or sepsis. No other part of the body has been affected. Treatment with various ointments has done no good. There is no itching. The patient has had, like most housewives, cracked fingers. As a child she had a "goitre," but the skin generally is normal now. Could, for example, plunging the hands once a week or so into waterglass when preserving eggs, or handling the baby's nappies and washing them and other household linen, start and maintain such a condition?*

A.—Much more information and investigation would be necessary to give a firm diagnosis, but a probable explanation is that an original damage from household or other irritants has favoured an infection of the skin. This may be of coccal or monilial or other fungous character. Protection from water and household irritants for a period and the use of a gentian-violet ointment at night and a cod-liver-oil cream by day should help:

Acid. salicyl.	gr. 5
Gentian violet	gr. 2½
Halden's emulsifying base	gr. 120
Paraff. moll.	ad 1 oz.

Ft. ung.

If the patient does not object to the colour by day, the cod-liver oil can be added to the violet cream in the proportion of 1 drachm to the ounce.

Explaining Mass Radiography to Workers

Q.—*A factory medical officer has been asked to do a five-minute broadcast to the workers asking them to volunteer for mass radiography. Many of the employees are non-cooperative; they fear that disease may be detected. What lines should the broadcast take to emphasize to all the workers the benefit of being examined?*

A.—Employees are undoubtedly somewhat apprehensive, and consider that any procedure advocated by an employer must be viewed with some suspicion. At the outset of the broadcast it should be stressed that:

1. The mass radiography scheme is a public health measure which, although indirectly beneficial to industry, has as its primary object the health and future welfare of the individual.
2. The result of the examination is strictly confidential between the mass radiography unit and the individual, and will not be disclosed or used in any way without the individual's consent.
3. Should an individual not wish to take any steps for treatment, no further action will be taken and the medical report will remain entirely confidential.

A few remarks on the reasons for mass radiography should follow, emphasizing the silent nature of the disease in the early and most easily curable stage. An analogy might be drawn between an incendiary bomb promptly and effectively tackled and one which by neglect has wrought irreparable damage.

The beneficial results of mass radiography should be elaborated as follows:

(*a*) *Benefit to the Individual.*—If present, the earlier the disease is detected the greater is the prospect of permanent cure, which in some cases can be accomplished without either sanatorium treatment or the necessity for leaving work. Delay in diagnosis frequently means permanent impairment of health, or at best a prolonged period of hospital treatment, before working capacity can be restored.

(*b*) *Benefit to the Wife, Family, and Fellow-workers.*—An undiscovered infectious case in their midst is a continual source of danger.

To alleviate anxiety about the examination, it could be pointed out that, of every thousand persons examined, approximately only ten show evidence of tuberculosis, and of these ten only four require sanatorium treatment. Should sanatorium treatment be necessary, financial allowances are available for both the individual, while under treatment, and his dependants. Last, but of no little importance, is the management's policy to an employee who may have to undergo treatment. If it can be said that his post will be kept open, or, if necessary, more suitable employment offered, this will greatly help in overcoming opposition. Propaganda on these lines has been found to elicit a response from between 70 and 90% of employees.

LETTERS, NOTES, ETC.

Car Without Foot Pedals?

Dr. J. RAMMELL writes: I should be grateful to hear from one of your correspondents as to the possibility of a patient's obtaining a car controlled without the use of foot pedals. The case in question is one of disseminated sclerosis in a young wife and mother, whose legs are insufficiently under control to render driving a possibility, but whose arms and mentality are such that she can drive a motor car. The chance of doing so would solve many domestic problems for her.

Unusual Complication of a Wasp Sting

Dr. B. WYLLIE (Harrogate) writes: A man 80 years old, while going to bed on the night of Aug. 11, 1945, was stung on the left side of the back of his neck by a wasp. As nearly as can be ascertained, the position of the sting was about one inch behind and slightly below the mastoid process. The following day there was marked reddening of the skin over a large area, but there was no great pain and movements were free. The same evening at 5 p.m. he noticed that the left side of his upper lip had fallen and that he was unable to move it. By 9 p.m. he had developed complete paralysis of the left side of his face, with retraction of the face to the opposite side and complete inability to close the eye. He complained of some pain behind the mastoid process. The inflammation round the area of the sting disappeared in a couple of days. Within a few days he started to recover, and now, fourteen days after the onset, there is a marked improvement. He can close the eye and move the muscles of the forehead, although the lower part of the face is still paralysed. The rest of his C.N.S. appears normal and, apart from a moderate degree of hypertension, he is remarkably healthy for his age. Bell's palsy is very rare at the extremes of age. It must be distinguished from peripheral facial paralysis, but the rapidity of recovery in this case helps the diagnosis. It is generally accepted that the paralysis is the result of a local inflammation of the nerve sheath, as it emerges from the stylomastoid foramen. In this case it would appear that the inflammation set up by the wasp sting reached the nerve sheath and thereby caused the palsy.

A Misnomer

Dr. G. J. JONES writes: Cannot something be done to stop this practice of referring to the sulphonamide group of drugs as "m and b tablets"? It seems to me to be a slovenly kind of slang unworthy of a profession. Moreover, the patient is usually told, "I am going to give you m and b tablets." Recently I saw a young woman who is a chronic neurasthenic of the first water. She had just returned from a convalescent home. Her fortnight at the sea had done us both good. She looked well and beaming. In the gayest manner possible she told me she had had a lovely time and had been ill and got m and b tablets. I assumed an air of ignorance and asked her what they were. She told me, "They were the same as Mr. Churchill got." I am sure she still thinks she battled with death. Possibly an aspirin tablet would have sufficed to reduce the slight pyrexia, but the beating of the wings of the angel of death would have sounded more like the unpleasant drone of an angry bluebottle.

Why "Hyperbaric" and "Hypobaric"?

CIBA LTD. write: With reference to the letter from Lieut.-Col. H. Williamson (Sept. 15, p. 368), we fully endorse his plea in the interests of accuracy and of patients' lives for the adoption of "heavy" and "light" in connexion with spinal anaesthetic solutions. In the *Nupercaine Handbook* and other literature, on labels, invoices, etc., the "nupercaine" spinal solutions have for some time been designated "heavy" and "light" in order to avoid any possible confusion resulting from the use of the terms "hyperbaric" and "hypobaric."

Wellcome Medical Diary, 1946

The 1946 Wellcome Medical Diary is now being printed. A considerable number of doctors have ordered copies, and these will be distributed early in December; any change of address since ordering should be notified to the address below. Shortage of paper has again resulted in a limited edition—only a few copies remain unallocated. Doctors who have not yet asked for a copy may apply to Burroughs Wellcome and Co., 183, Euston Road, London, N.W.1. Every effort will be made to ensure that medical men returning to civilian practice receive their diary.

ARTERIAL ANEURYSM FOLLOWING INJURY TO ILIAC VESSELS

REPORT OF TWO CASES, WITH A COMMENTARY ON LARGE TRANSFUSIONS

BY

H. AGAR, F.R.C.S.
Major, R.A.M.C.

JOHN ROWLANDS, M.R.C.S.
Surgeon, E.M.S.

AND

W. H. OGILVIE, F.R.C.S.
Late Surgical Consultant to Eastern Command and E.M.S.

The cases recorded below have several points of interest in common. They are examples of arterial aneurysm following war wounds; they involved in each case ligature of more than one iliac artery; the operations were accompanied by profuse and rapid haemorrhage, to combat which profuse and rapid transfusion was necessary; recovery of life was undoubtedly due to the promptness and completeness with which the blood loss was made good, and recovery of the limb, in the second case at any rate, to the application of the principle of physiological sympathetic release. Both patients were treated in the Eastern Command—one at a military, the other at an E.M.S., hospital.

Case I: Aneurysm of the Buttock. By H. Agar

During the night of Sept. 3, 1942, Gnr. W. J., aged 29, was wounded in the right buttock by a mortar-bomb splinter. He bled considerably and was unable to walk, and lay in the Desert until found by the Germans next day. Dressings were applied until three weeks later, when he reached hospital in Italy, where the wound was explored superficially without an anaesthetic. The patient was not told of any unusual feature. By December the wound had healed and he could walk with a limp, but a swelling about 2 in. in diameter remained. He was transferred to a prison camp, but soon the leg began to feel heavy and he was admitted to hospital. He reports that a diagnosis of aneurysm was made. In Aug., 1943, the buttock rapidly increased in size and became painful. Thereafter he was bed-ridden and had to lie on his left side with the right thigh flexed. There was further enlargement with increase of the pain in June, 1944, and afterwards he could not extend his right thigh.

He was repatriated and admitted to a military hospital on Oct. 11, 1944. He looked ill and the right buttock was painful. It was enormously enlarged, projecting about 4 in. beyond the left, and the skin over it was tense and buff-coloured. It was impossible for him to lie in any position other than on his left side with the right thigh flexed. Palpation revealed extreme tenderness, and a little pulsation could be detected at the periphery. There was no bruit. The thigh could not be moved more than 5°. The muscles of the thigh and leg were wasted but not paralysed, and sensation in the limb was normal. Blood count: R.B.C., 3,280,000; Hb, 62%; C.I., 0.95; W.B.C., 24,800 (polymorphs 85%, lymphocytes 10%, mononuclears 5%, eosinophils and basophils *nil*). Wassermann reaction negative. Radiography did not show any bone defect and the lung fields were normal. There was evening pyrexia up to 99.6°. Aspiration in two places revealed fresh blood under pressure but no old blood.

During the next week pain and pyrexia increased and the haemoglobin fell to 40%. The foot became anaesthetic, with paralysis of both flexors and extensors of the leg, which showed impaired response to faradism.

The differential diagnosis appeared to lie between sarcoma—that on which he was repatriated—and aneurysm. Points in favour of sarcoma were the late appearance of the swelling after wounding, the huge size and preponderatingly solid consistency of the tumour, the brown discoloration of the skin, and the small amount of pulsation that could be detected. Those supporting aneurysm were that the enlargements had occurred at intervals, that radiography revealed no bone destruction and no metastases in the lungs, and that aspiration had disclosed blood under pressure in two places.

It was decided that operation alone could help the patient. After three pints of packed red cells and two pints of whole blood had been given in three days, the haemoglobin rose to 70%. Although he had a temperature of 103.5° on the day of operation, it was decided to proceed. Anaesthesia was induced by 10 c.cm. of 1/1500 spinal nupercaine, given with the patient on the left side, and supplemented by inhalation gas-and-oxygen. The right external and internal iliac arteries were exposed retroperitoneally and tapes passed round each. A long incision was made across the buttock in the direction of the fibres of the gluteus maximus, which were pale in colour and did not bleed. They were separated carefully, but there was a sudden gush of both fresh and old blood. The cavity was fully opened and packed. Blood pressure fell immediately to 70 mm. systolic, but three pints of blood, given rapidly, produced considerable improvement. The arteries were controlled, but severe bleeding recurred when the pack was removed. Rapid exploration revealed bare bone near the sacro-iliac notch and that most of the bleeding came from that region. The wound was repacked, the right internal iliac artery was tied, the right external iliac released, and the left internal iliac artery exposed retroperitoneally and tied. This greatly reduced the bleeding, but it was not possible to stop it altogether. The wound was finally packed and the patient returned to the ward with a pulse rate of 130 and a systolic blood pressure of 70, 14 pints of blood and 4 of plasma having been given during the operation.

Blood drip was continued, and after two hours the pulse rate was 120 and the blood pressure 130/80. The circulation in the right leg was noticed to be deficient, and in spite of keeping the limb cool there was early necrosis of skin over the tendo Achillis and os calcis as well as of all the toes. A further two pints of blood and two of plasma were given by drip during the 24 hours following operation.

After 36 hours his condition was deteriorating and a foul-smelling discharge from the wound was observed. Under gas-and-oxygen anaesthesia it was reopened and gas gangrene of the remnants of muscle and laminated aneurysmal wall was revealed. A large amount of necrotic muscle and capsule was removed. The deep part of the pack was not disturbed, but the rest of the wound was left open. Penicillin was given by continuous intramuscular drip at the rate of 15,000 units three-hourly for seven days. During the second operation it was noticed that the circulation in the leg improved when the hip was flexed. Thereafter the thigh was gradually extended over several days and the circulation remained adequate. The pack was removed on the seventh day without any recurrence of bleeding. At the same time some slough was removed from the surface of the deep muscles, and secondary suture was successfully performed on Dec. 22, 1944.

By February most of the slough had separated from the heel; some superficial necrosis of the os calcis was revealed by radiography, but the bone was covered with healthy granulations. There was full and controlled movement of the knee and sensation in the leg was returning, but the muscles below the knee reacted only to galvanism. Abduction and hyperextension of the hip were limited. In spite of persistent daily efforts to maintain full movements of the toes and ankle, all joints have gradually stiffened and dorsiflexion of the ankle beyond 90° is not possible. This suggests that fibrosis has occurred in the muscles of the leg, probably as the result of the post-operative ischaemia.

The treatment demonstrated the importance of giving sufficient blood before, during, and after operation. In spite of having 27 pints in four days there was no reaction. It is satisfactorily shown that ligation of both internal iliac arteries can be performed without anxiety for the circulation in the rectum and pelvic organs, and there was no evidence that it was a factor in reducing the circulation in the limb. The efficiency of penicillin together with adequate surgery in the treatment of gas gangrene is well shown, as no serum or other treatment was given. The rapidly increasing anaemia and pyrexia, which were difficult to explain before operation, were probably due to infection in the wall of the aneurysm.

It is intended to apply small Thiersch grafts to the heel and replace them later by a pedicle flap in the hope that it will withstand weight-bearing. Should it fail, a below-the-knee amputation will be considered, although the limited control of the hip-joint will weigh heavily against such a decision.

I wish to express my thanks to Lieut.-Col. T. Scott-Law, R.A.M.C., for permission to publish this case.

Case II: Retroperitoneal Aneurysm. By John Rowlands

This patient, Lieut. U. M., a German prisoner of war, was wounded at 14.00 hours on Feb. 8, 1945. He appeared to have been hit by a bullet which entered on the lateral aspect of the right buttock and emerged from the left flank at a slightly higher level. His condition on arrival at a field surgical unit was poor, but his abdomen was soft and tender. He was given two pints of blood and one of plasma, after which laparotomy was performed (30 hours after wounding). The operation notes state that there was an extensive retroperitoneal haematoma "everywhere," but that no perforation of bowel or mesentery was found, the bullet having apparently passed behind the base of the mesentery. Routine post-operative treatment was given, and the patient was evacuated as a lying case on Feb. 19.

On arrival at a British general hospital two days later he was found to have a distended abdomen and a large mass palpable in the pelvis. His temperature was 99.6°, but his general condition was satisfactory. He had paralysis of the anterior group of thigh muscles on the left and some anaesthesia on the inner side of the thigh.

He was seen by Lieut.-Col. McArdle, Neurological Adviser, who reported complete paralysis of the left quadriceps group, a flicker in the abductors, and good contraction in the hip flexors. The anterior and posterior tibial muscle groups were normal. There was complete sensory loss over the distribution of L 2 and 3 roots, and marked impairment over the sensory area of L 4. The knee-jerk was absent. He bent the hip to 30° with the knee flexed. The recorded diagnosis was a lesion of the upper roots of the lumbar plexus—complete of L 2 and 3 and partial of L 4.

He was evacuated to England, and reached an E.M.S. hospital on March 4. He was in fair general condition, but looked thin and pale and slightly jaundiced. He complained of thirst and of inability to keep down solid food, and said that his bowels, previously regular, had not been opened for five days. The laparotomy wound and the small entry and exit wounds were well healed. On the left side of the abdomen a large mass could be seen, which seemed to be rising from the left side of the pelvis, but no pulsation was visible. On palpation it appeared to be about the size of a foetal head. A thrill was present and a well-marked systolic souffle could be heard. The paralysis recorded in his Army notes was still present, and, in addition to the physical signs there described, there was complete absence of pulsation in any of the great vessels of the left leg: there was no venous congestion of the leg, but a few dilated veins could be seen over the upper part of the thigh and the side of the pelvis.

The patient complained of pain on any attempt at extending the hip, which was held in flexion, but was unaware that he had sustained a severe hot-water burn on the inner thigh. After an enema he passed a good constipated motion with no blood or pus. Examination of the rectum revealed no abnormality. The urine was normal. A blood count showed 3½ million red cells per c.mm., 56% haemoglobin, and 14,350 white cells per c.mm. with 80% polymorphs. A straight radiograph showed no bony injury. An intravenous pyelogram and barium enema were carried out in an attempt to define the tumour; the ureter could not be seen, but the iliac colon was observed to be displaced forwards and medially. A provisional diagnosis of "a leaking perforation in the external iliac artery with a gradually increasing retroperitoneal haematoma" was made.

On March 9 two pints of fresh blood were given, and though the patient's general condition improved after the transfusion it was clear that the abdominal swelling was increasing in size. Major-Gen. Ogilvie saw the patient in consultation on March 13, and performed laparotomy on March 15, six weeks after the injury.

The abdomen was opened through the old paramedian incision, which was considerably lengthened. A large retroperitoneal tumour was seen to occupy the whole left side of the lower half of the abdomen. The colon and small intestine were displaced towards the midline. The abdominal aorta in its lower half and the origin of both iliac vessels were covered by the tumour. The aorta was exposed by dissection at the upper margin of the tumour, on the body of the second lumbar vertebra, and found to be slightly displaced to the right; it was isolated, and a tape was passed behind it to allow digital compression to be applied.

The tumour was then opened by a wide curved incision one inch outside and parallel to the displaced iliac colon, while the aorta was compressed by an assistant. A large quantity of fluid blood escaped, after which several handfuls of clot were scooped out, exposing a large cavity with an endothelial lining. At this point the vertical laparotomy incision was extended by a transverse one running outwards from its mid-point. On dissection in the inner wall of the cavity towards the pelvic brim, a rent was seen on the lateral aspect of the internal iliac artery just below its origin, from which copious haemorrhage took place as soon as digital compression of the aorta was released. This rent was closed above and below by silk ligatures, but so near was it to the origin of the vessel that its upper end could not be properly controlled, even though three successive ligatures were applied. The tear could be excluded by a haemostat placed obliquely without shutting off the passage of blood from the common to the external iliac arteries, but the alternatives that then presented themselves, of attempting arterial suture of a lateral opening in a large vessel already considerably traumatized or of returning the patient to bed with the haemostat in position, seemed to carry greater danger than ligature of the vessels. The common, internal, and external iliac arteries were therefore ligatured, and the haemorrhage satisfactorily controlled. The lumbar plexus was not inspected. The cavity was lightly packed with vaselined gauze and drained with a strip of corrugated rubber—gauze and drain being brought out at the lateral end of the transverse incision. The posterior peritoneum was closed over the operation site, and the abdominal incision was sutured in layers. During and immediately after the operation 5½ pints of stored blood and 1 pint of fresh blood were given.

The condition of the patient on his return to the ward was satisfactory, though the left leg felt very cold. When consciousness was recovered, sensation in the limb was present apart from the previous areas of anaesthesia. There was slight bluish discoloration of the big toe and medial side of the foot for the first 24 hours only. The blood pressure rose steadily, and 24 hours after operation was 178/135, but there were no signs of circulatory overload.

Subsequent progress was satisfactory. The laparotomy incision healed well. The drain was shortened in 48 hours and removed on the fourth day, and the vaselined gauze was taken out in stages during the first week. There was some distension and hiccup during the first 24 hours, but thereafter distension decreased rapidly and the bowels began to move. The leg became warmer, and pulsation was recognizable in the tibial vessels after 10 days. A small collection of pus presented at the drainage opening 18 days after operation; a penicillin-sensitive *Staphylococcus aureus* was grown on culture, and the infection yielded rapidly to a short course of penicillin. There has been no improvement in the power of the paralysed muscles, but sensation has returned over the area supplied by L 4. Exploration of the lumbar plexus in the line of the track may be undertaken at a later date.

I should like to thank Col. W. L Watson, O.B.E., I.M.S., for permission to publish this case.

Commentary on the Above Cases. By W. H. Ogilvie

In each of these patients the surgeon was faced, during the course of the operation, with haemorrhage at a rate with which transfusion could not possibly keep pace, and the only way to avoid an immediate fatal issue was by applying a temporary packing and interrupting the operation till the circulatory volume had been restored to a reasonable level. In the first case the injured vessel, which lay deep inside the pelvis, was never in view, and during alternate search and resuscitation the patient received an amount of blood that exceeds that in any report of which I have knowledge. In the second case the tear in the artery was soon defined, and, after some tentative ligatures on the origin of the internal branch, finally arrested by ligature of the common, internal, and external iliac arteries.

In each patient the affected limb was left uncovered outside the bedclothes at room temperature, while the body and the other limbs were warmed under an electric cradle. The vasodilatation obtained in this way probably exceeds that following injection or resection of the sympathetic chain.

In the first case, in which both internal iliac arteries were tied, the pelvic organs, which should have suffered maximum deprivation, did not give any evidence of damage. The heel, on the other hand, supplied by the external iliac artery which was not tied, showed arterial gangrene. This mishap was apparently caused by spasm or actual mechanical obstruction of the external iliac and femoral arteries when the limb was straightened on return to bed. The vessels had probably become shortened by prolonged flexion of the thigh during the period when the patient was bed-ridden, and the events indicate the necessity for gradual change in position after a limb has been held in an unusual attitude for a long time.

In the second case the nutrition of the limb never seemed to be in danger, even though not merely all the iliacs, but the epigastric anastomosis which forms the most obvious collateral channel, had been tied. The compensatory circulation must have been by blood entering the ligatured internal iliac through anastomoses with the lower lumbar arteries, the middle sacral, and the branches of the opposite internal iliac artery, and passing into the external iliac and femoral arteries through anastomoses between the ilio-lumbar and the deep circumflex iliac, the gluteal and the external circumflex, the obturator and internal circumflex, the sciatic and the superior perforating, and the internal pudic and the deep external pudic.

The most striking advance in surgery during the last four years is, without question, the progress that has been made in the use of whole blood. Improvements in operative technique have allowed us to do many things a great deal better than we used to do, sometimes with half the mortality. The sulphonamides and penicillin have increased the cure rate in venereal disease and allowed the early closure of war wounds in a high proportion of cases and with greater certainty than was formerly possible. But blood, used in the quantities and at the speed that we have been taught to use it, has introduced a new therapeutic principle, allowing us to save useful lives that have never been saved before. Without the provision and adequate administration of large quantities of blood a man with an injury to a large artery will certainly die; with it he can recover, and recover with perfect function. Loss of blood is not, like loss of any other tissue of the body, irreplaceable: bone and skin defects can be compensated by borrowing from other parts of the body, but the result is a good repair, not a normal restoration; blood, though it is the fuel of the corporal machine, is not an individual tissue, but one that can be replaced in any quality and quantity from a well-equipped filling station. Injury to an artery is not, like injury to any other structure, irreparable: for whereas muscles and nerves are unique, an artery is one of many alternative channels, the remainder of which will take over and supply the same areas with the same substance when one is gone.

Yet there seems to be a temperance campaign against blood, as if it were a fluid as disreputable and as liable to abuse as beer. We are constantly told that it is used too often and in too great quantities, never that it is used too seldom and too timidly. Articles without number are written about the dangers of blood, about Rh factors and reactions; none about the thousands of men who are alive to-day only because blood was ready for them as they came out of battle and given courageously. Post-traumatic anuria is discussed in every journal, the writers taking the line, "We can't prove that transfusion was responsible, but it looks mighty suspicious": the more rational interpretation—that "the patients who developed an anuria were men who had been in severe shock of sufficient degree to produce a relative renal ischaemia and that this ischaemia was maintained for sufficient time to cause a large amount of kidney damage,"* that is that the men developed anuria not because they were given too much blood but because they were given too little or it was given too late—though one widely held by forward surgeons, is apparently suppressed as running counter to the views of the haemophobes.

It is often said that few patients need more than three pints of blood; it would be truer to say that patients who need only three pints of blood do not need blood at all. A loss of two pints can be made up by fluid administered by mouth. A loss of three pints can be remedied reasonably well by transfusion of plasma. A loss of even four pints need not end fatally if the volume is restored fully and promptly by plasma, though with a haemorrhage of this extent some at any rate of the replacement should be by blood. But when not only is the blood loss considerable but further, considerable loss is expected, it is necessary to have large amounts of reliable blood ready for immediate administration. And this means a blood bank. To rely upon a group of donors, however ready they may be, is to court failure in cases where large amounts of blood could really save life. For no haemorrhage, however profuse, need be fatal if the rent from which it is pouring can be stopped. Blood loss, even from a vessel the size of the common iliac, can be stopped by packs and firm pressure; and though transfusion cannot possibly keep pace with the loss while bleeding is going on, the blood can be run in at the rate of a pint in two minutes by using both arms simultaneously, and the circulatory volume can be restored while the surgeon presses the pack in position, ready, at a signal from the transfusion officer, to remove it and make another attempt to control the bleeding hole more permanently.

Blood transfusion has undoubtedly got its dangers, but they are for the most part associated with the giving of blood to those who are gravely ill and who have been repeatedly transfused over a long period. Good blood prepared by a good transfusion service, and given by a good transfusion officer who can detect a doubtful bottle at sight and stop an incompatible transfusion at the first sign of reaction, seems to have no dangers in the type of massive post-traumatic haemorrhage in which it offers the only means of saving life.

CUTANEOUS SCHISTOSOMIASIS INVOLVING S. HAEMATOBIUM EGGS

BY

K. O. BLACK, M.D., M.R.C.P.
Major, R.A.M.C.

Although the eggs in human schistosomiasis are deposited chiefly in the bladder and bowel, they are known to occur elsewhere, and may be found in organs drained by the systemic system. Deposits of the eggs of *Schistosoma haematobium* in the lungs, brain, spinal cord, heart, and kidneys are well recognized, and are mentioned in the textbooks. Deposits in the skin have, however, rarely been recorded in the literature, and are not referred to in the standard textbooks. Madden (1919) described deposits of eggs in the subcutaneous tissues, especially in the perineum, but also in the "bathing-drawers area" and rarely elsewhere, giving rise to fibrous nodules. He pointed out a resemblance to tuberculous subcutaneous nodules in the earlier stages, and continued as follows: "These nodules, or chain or irregular collection of nodules, are at first hard, then gradually enlarge and soften, and ultimately burst through the skin and discharge a thick dirty cheesy material and persist as a sinus, or as a fistula in more or less free communication with an adjacent organ or mucous surface." Girges (1934), in an account of the various sites affected in the case of *S. haematobium*, says: "Small, deep-seated, separate, multiple, elevated, dark-coloured deposits occur in the subcutaneous connective tissues in the perineum, penis, and scrotum, over the sacrum and coccyx, and particularly over the pubis, forming hard nodules closely resembling tuberculous glands. They may grow and become adherent to the skin, soften and open to the exterior, forming sinuses," which "are not as a rule connected to the neighbouring viscera." Garcia *et al.* (1940) described the case of a Filipino child with a chronic ulcer of the leg, sections of which showed the presence of *S. japonicum* eggs. The present paper describes two cases of schistosomiasis which developed a distinctive skin lesion, from which eggs of *S. haematobium* were recovered by aspiration, identical with those seen in the stools and urine in the course of investigating 130 European cases of schistosomiasis admitted to a West African general hospital in 1944. Two other cases are included because they had similar lesions, although ova were not recovered from the skin.

Case I

A British N.C.O. aged 21 had bathed in a freshwater lagoon in Southern Nigeria every day for five weeks from Jan. 23, 1944, in the course of training for jungle warfare. He frequently had to leave the water because of skin irritation, and had periods of itching during the nights after bathing. The itching affected his whole body, but was worst on the legs. He remained well until March 12, when he developed cough, aching in the back of the neck, and nasal discharge which lasted for three days. On the fourth day he had a feeling of extreme weakness with diarrhoea, and his temperature rose to 101.2° F. On the fifth day he developed widespread urticaria and was admitted to hospital. The urticaria faded after three days, but an irregular pyrexia persisted for two weeks, during which the symptoms gradually subsided. The white cell count was 8,400 per c.mm., with an eosinophilia of 12%. Examinations of urine, faeces, and blood films were negative. After this illness he remained well except for the cough, which persisted, and occasional diarrhoea and abdominal discomfort. On May 3 the stool was found to be streaked with blood-stained mucus, in which eggs of *S. haematobium* were found. The white cell count was 9,000 per c.mm., with 19% eosinophils; the urine deposit was normal and contained no ova. The symptoms at this time were diarrhoea, abdominal pain, and cough which invariably troubled him at night.

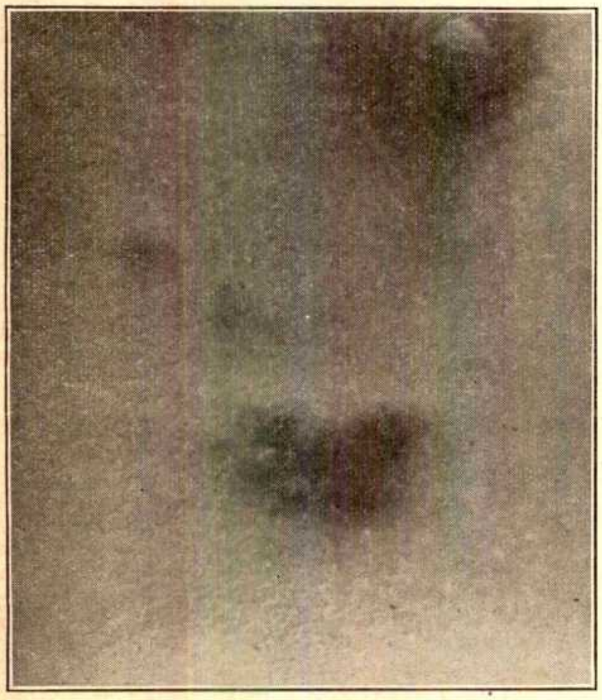

FIG. 1.—Case I. Cluster of skin deposits.

Treatment with 40 c.cm. of stibophen, given by intramuscular injection over a period of 15 days, was started on May 6. On May 13 the patient drew attention to a skin lesion below the right nipple, which rather resembled and was at first thought to be herpes zoster. He had previously (May 1) noticed some spots on the scrotum, which cleared up within 10 days. The lesion below the right nipple had appeared about May 3 as a small group of pink spots which could be felt with the finger and gave a sensation of slight soreness but not pain. As fresh spots occurred in the same area they were first pink and later violet. When examined on May 13 the lesion (shown in Fig. 1, at a later stage) consisted of a crowded cluster of shotty papules of a violet colour and two outlying pink papules which had been the last to appear. Fresh clusters of papules developed during and after the stibophen course. In the latter part of the course each group contained fewer papules, many of which remained pink and small, and shrank and atrophied although some induration was detectable for several weeks. The lesions were confined to the lower chest and upper abdomen in front, and the lower part of the back and upper part of the buttock behind.

The appearance of unrecognized skin lesions in a proved case of schistosomiasis, at about the time when eggs were first discovered in the faeces, suggested that they might be a manifestation of this disease. Accordingly tissue juice, sucked from the lesions by means of a small needle and syringe, was examined. On May 15 no eggs could be found. On May 21, after several attempts, scanty *S. haematobium* eggs were seen. By June 8 some of the violet indurated nodules on the right flank had developed a whitish apex resembling a small pustule. The contents, removed with a needle, were white and pasty, and contained large numbers of *S. haematobium* eggs, as many as five being seen in some low-power fields. Some were degenerate and opaque, but others seemed healthy and structurally perfect. After the stibophen course the stools remained normal and free of eggs for three weeks, but on June 14 blood and mucus reappeared, eggs were found, and sigmoidoscopy showed active disease in the rectum. Fresh skin lesions began to appear on the scrotum (Fig. 2) as clusters of nodular pink papules which were soon surmounted by a white spot the size of a pinhead. On June 26 the contents of one of these spots were examined and two degenerate eggs of *S. haematobium* were seen, the shell and spine being intact, but the contents granular and structureless. By the middle of July there were numerous papules on the scrotum, perineum, and root of the penis, mostly arranged in groups. Eggs were obtained from these on numerous occasions. The papules were less regular in shape and more variable in size than those on the trunk; they were nodular and took on a distinctly violet colour. On the trunk two groups of lesions which had appeared during treatment and had atrophied without passing through the violet papular stage were still distinguishable as definite elevations at the sites of the original papules. The remainder had become rather softer but were still definitely nodular, with a shiny, pearly top and some wrinkling of the overlying skin. Constipation and abdominal pain became troublesome and pain on micturition developed for the first time. Eggs, with pus and red cells, now appeared in the urine as well as in the faeces. The liver edge was palpable on inspiration, smooth, firm, and not tender. There was tenderness on palpation of the right and left iliac fossae. The white cell count was 11,000 per c.mm., with 9% of eosinophils. A second course of 40 c.cm. of stibophen was given, during which no further skin lesions appeared.

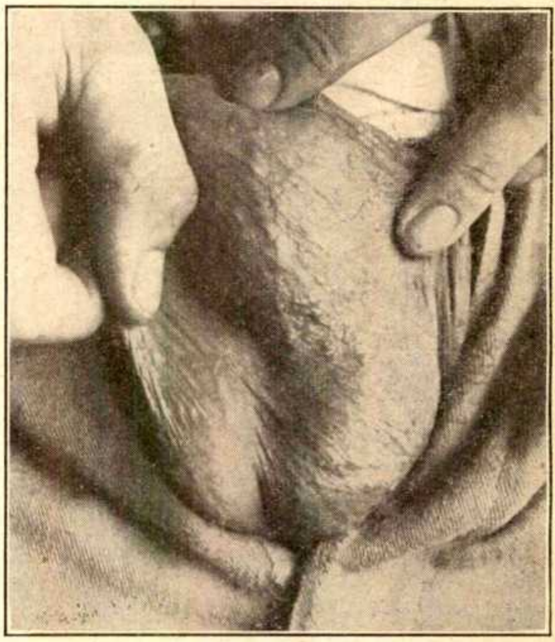

FIG. 2.—Case I. Scrotal lesions.

Case II

A British N.C.O. aged 28 had bathed almost every day for a month from Jan. 24, 1944, in the same lagoon as Case I. He itched all over the body after leaving the water, and towards the end of the month was troubled with an itchy and prickly rash which he described as like little pinheads, some watery, faint in the morning but red and irritating at night-time. He remained in normal health until March 3, when he was admitted to sick quarters with headache, shivering, and a temperature of 102.6° F. His temperature fell gradually to 100° F. during the first five days, with a daily fluctuation of less than one degree. In the next 10 days his temperature was 99 to 100° F. most evenings, and normal in the mornings. There was no further shivering after the onset, but headache continued, and on the fifth day he developed a dry cough and a rash on the front and back of the chest. He was transferred to hospital, with a tentative diagnosis of dengue, on the eighth day, by which time the rash was fading rapidly. The eosinophils rose in this illness from 1 to 34%, the total leucocyte count remaining between 5,000 and 7,000 per c.mm. Examination of stools, urine, and blood films was negative. After the temperature reached normal he felt quite well and was allowed to return to his unit. Weekly stool examinations were negative and the eosinophil count fell to 15%, but he began to have periodical looseness of the bowels and abdominal discomfort, and was readmitted to hospital on May 4. He now complained of itching of the penile urethra, and the abdominal pain was worse. The stools were formed, with strands of mucus on the surface which were found to contain eggs of *S. haematobium*. The urine deposit remained normal. The eosinophil count had risen to 39%.

On May 8 treatment with stibophen was started. On May 13 a group of pink papules was noticed in the left lumbar region. The papules were about 3 mm. in diameter, and were palpable as small shotty nodules. On May 15 a second group appeared on the lower left chest in front. A small amount of milky fluid was obtained by aspirating one of the nodules and found to contain one perfect healthy-looking ovum of *S. haematobium*. Four further clusters and some scattered papules subsequently appeared on the left lumbar, sacral, and gluteal regions (Fig. 3). A course of 50 c.cm. of stibophen was given, after which the skin eruptions ceased. The skin lesions in this case were similar to those in Case I. Starting as firm nodules which projected above the surface as pink papules, they developed red areolae which became confluent. By June 6 the clustered papular lesions had taken on a dull-red colour. On June 16 the nodules had become soft and the overlying skin was atrophic, shiny, and somewhat wrinkled, and of a violet or purplish colour. No ova could be found by aspiration at this time. The patient remained well, and repeated stool examinations were negative for five weeks. The eosinophil count, however, remained high (38–39%), and early in July ova appeared for the first time in the urine, and shortly afterwards again in the stools, and a further course of treatment was started.

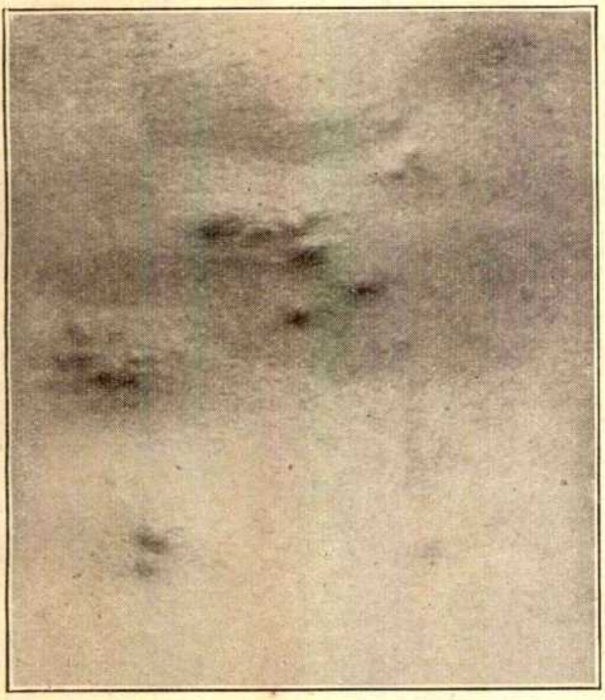

FIG. 3.—Case II. Skin deposits. (The shadows are due to uneven developing of the negative.)

Case III

A British N.C.O. aged 27 had bathed in the same lagoon every day for four weeks from Feb. 4, 1944, and had a slight tingling sensation of the skin at the time of bathing. Toxaemic symptoms started on March 12, and nocturnal cough, diarrhoea, and abdominal pain persisted until admission to hospital on May 9. Ova of *S. mansoni* were found in strands of russet-coloured mucus on the surface of the stools. The urine deposit was normal and there was no eosinophilia. A course of 50 c.cm. of stibophen was given, after which the stools were free of ova and the patient was allowed to rejoin his unit, to remain under out-patient surveillance. He still had nocturnal cough, and when seen on June 16 there were two clusters of pink papules in the lumbar region which, he said, had been present for three days. Ova could not be found in the faeces, but there was now an eosinophilia of 11%. When seen again ten days later the spots were still present and *S. haematobium* ova were seen in the faeces. The urine contained pus and red cells, though repeated examinations failed to disclose ova. The patient was readmitted and given a second course of stibophen, after which the spots gradually atrophied. The lesions in this case lasted for over six weeks, and closely resembled those seen in Cases I and II, though ova were not found in them.

Case IV

A British N.C.O. aged 21 had bathed in the same lagoon every day for a month from Feb. 13, 1944. He had a prickling sensation after bathing, and noticed a rash like "prickly heat" on the limbs and trunk. He first felt ill about March 20 with headache and tiredness, followed by irritating cough and abdominal pain. On April 25 blood and slime were noticed in the stools and he was admitted to hospital. *S. haematobium* ova were present in large numbers in the mucus, and there was an eosinophilia of 55%. A course of stibophen was given, the last injection on May 18, after which the stools were macroscopically normal and free of ova. The symptoms were relieved and he was discharged, to be kept under out-patient surveillance. Soon, however, cough, headache, and abdominal pain returned, and two weeks after the end of treatment he developed a group of spots to the right of the umbilicus. On June 21 he was readmitted, and *S. haematobium* ova were found in the stools and later in the urine. An unusual symptom, haemospermia, was reported, and the prostatic fluid was found to contain pus, red cells, and ova. Fresh skin lesions continued to appear on the lower chest up to and during the second course of treatment, after which the symptoms were relieved. Stools, urine, and prostatic smear showed no abnormality, sigmoidoscopy was negative, and no further skin lesions appeared. The lesions in this case persisted for two months, and were similar to those seen in the foregoing cases.

Discussion

The four cases described were heavily infected by repeated bathing over a period of a month or more. Each developed a definite toxaemic stage after an incubation period of several weeks; and local disease, indicated by the passage of eggs, about three months after the first bathe. In each case the eggs appeared first in the faeces, and in three cases later also in the urine. Skin lesions appeared when local disease was established—in Cases I and II at about the time when eggs were first found in the faeces, and in Cases III and IV some two weeks after a course of treatment which was followed by the reappearance of eggs in the excreta.

The characteristics of the lesions, though apparently modified as to the degree of local tissue reaction by antimony treatment, were sufficiently constant and striking to be easily recognizable, and distinct from the more familiar skin complaints. In each case they first appeared as deep, shotty pink papules 3 to 5 mm. in diameter, arranged singly or in clusters which appeared successively. There was sometimes transient local oedema with itching at first, which passed off in a few days, after which there were no symptoms, or merely a slight soreness. An area of erythema developed round each papule, and these areas became confluent within the clusters. The original papules remained distinct, and their nodular character was perceptible for six weeks or more. They changed to a dull red and then to a purplish or violet colour. Some groups and scattered papules which appeared during treatment failed to develop beyond the pink stage and slowly atrophied. The others enlarged somewhat and became softer, with wrinkling of the overlying skin. Finally a white spot appeared at the apex, the contents of which were white and pasty. The resemblance of the lesions at some stages to those seen in the bladder and bowel at endoscopy was striking.

The lesions described here correspond fairly well with the early stages of those described by Madden and by Girges—viz., small subcutaneous nodules, at first hard and later enlarging and becoming softer. Madden refers to the arrangement of the nodules in chains or irregular collections, and Girges mentions that they are elevated and dark in colour, and may discharge a cheesy material. The later stages of ulceration and sinus formation, as described by these authors, were not seen in the cases recorded here, which came under treatment at an early stage.

Madden gives the distribution on the body as: especially in the perineum, but also in the "bathing-drawers area," and rarely elsewhere. Girges includes the perineum, penis, scrotum, over the sacrum and coccyx, and particularly over the pubis. The scrotum, perineum, and root of the penis were heavily involved in one of the cases described above. Posteriorly, the majority of lesions were in the lower part of the back and upper part of the buttocks, though occasional ones were seen as high as the scapular angles. So far the agreement is quite close, but anteriorly the distribution was rather different, the area affected being higher—chiefly between the levels of the nipples and navel.

Paired *S. haematobium* worms may wander from their habitat in the pelvic plexuses of veins into the inferior vena cava, and Fairley (1919) found them in the inferior vena cava in necropsies on infected monkeys. From the iliac veins and vena cava they might ascend the scrotal, gluteal, and lumbar veins by their normal process of travelling against the blood stream. The lesions in the lower part of the chest and upper part of the abdomen are more difficult to account for: possible routes would be via the venous communications between the lumbar and epigastric veins, or from the external iliacs via the inferior epigastric veins.

The nature of the nodules remained in doubt until eggs were obtained by puncture with a fine needle and withdrawal of a little tissue juice by suction with a syringe. The eggs were identical with those seen in a large number of examinations of stools and urine. Some were structurally perfect, while others, especially after treatment, showed no miracidial structure and had granular contents or were opaque. Tissue was obtained by biopsy from two of these cases, but when examined later the embedded material was found not to include any of the actual tissue from the nodules.

Compared with the skin affections due to cercarial penetration, and the urticaria of the toxaemic stage, cutaneous lesions arising during the stage of established local disease and associated with deposits of eggs have attracted little attention. The lesions described here were practically symptomless, and were noticed only because the white patients, being fastidious about skin complaints in the Tropics, drew attention to them. It seems quite likely, therefore, that this condition might fail to arouse the comment of native patients. Large outbreaks of schistosomiasis among Europeans are unusual, and with an incidence of only about 3% in, for the most part, heavily infected cases under observation in hospital, this complication would no doubt be of rare occurrence in normal practice.

Summary

In a series of 130 cases of schistosomiasis in Europeans, four cases were seen with a distinctive skin lesion. In two of these the lesions appeared at about the time when eggs were first discovered in the faeces. Tissue juice, aspirated from cutaneous nodules, was found to contain eggs of *S. haematobium*, identical with those seen in the urine and faeces. The skin lesions in the other two cases appeared about two weeks after unsuccessful treatment with stibophen, which was followed by the reappearance of eggs in the excreta. The lesions were similar, but eggs were not recovered from them.

The lesions and their distribution are compared with those previously recorded, and the way in which eggs may reach the skin is discussed.

I wish to thank Major-Gen. A. G. Biggam, C.B., O.B.E., for his help and for permission to publish this paper; Prof. R. T. Leiper, C.M.G., for his interest and for two of the references to the literature; and Dr. George Graham for much stimulating advice and help.

METHODS FOR DETERMINING PLASMA PROTEINS

VALUE IN A GROUP OF BOYS AGED 14 TO 15

BY

R. P. COOK, M.B., D.Sc.

D. M. KEAY, M.B., D.P.H.

AND

D. G. McINTOSH, M.B., D.P.H.

(From the Department of Physiology, University College, Dundee, University of St. Andrews, and the Public Health Department, Corporation of Dundee)

We have determined the plasma proteins of a group of 45 normal schoolboys aged 14 to 15. Information as to the social condition and diet of the boys is given in a previous publication (Cook, Davidson, Keay, and McIntosh, 1944). As a considerable volume of plasma was obtained there was an opportunity of testing various methods of estimation. The standard method is the gravimetric estimation, in which the total proteins are isolated and weighed. To this method all others should be subservient. It should be stressed, however, that whether plasma "proteins" can be regarded as a distinct chemical species is a moot point. Particularly is this so in the mixed form in which they occur in the blood. In view of the importance of the determination of plasma proteins in clinical medicine and in nutrition surveys we present our results with some practical details in the hope that they will be of value to other workers in this field.

Methods

Collection of Blood and Preparation of Plasma.—Since other blood constituents such as vitamin A and ascorbic acid were to be determined it was necessary to withdraw 40 ml. of blood from each boy. As an anticoagulant potassium oxalate was used. Into a tube prepared to contain 20 ml. of blood 1.5 ml. of 6% (w/v) solution of potassium oxalate was placed. The tubes were put on a metal tray and the solution evaporated to dryness (leaving a deposit of oxalate crystals) by gentle application of heat from a Bunsen burner. Overheating, which converts oxalate into carbonate, must be avoided (Harrison, 1937). The syringe used for withdrawing blood was previously flushed out several times with sterile saline. The small amount of saline left might be regarded as a diluent of the blood, but experiments on haemoglobin determinations using a completely dry and a saline-moistened syringe show that at most a dilution altering the results by 1% is obtained. The boys were seated during the puncture of the vein, a rubber tourniquet being loosely applied round the middle of the upper arm. As soon as the vein was entered the tourniquet was slackened. It was sometimes found necessary to apply slight pressure during the withdrawal of the sample. The oxalated tube was gently rotated during the addition of the blood. In no case was there any coagulation. Haemolysis to a slight degree occurred with three samples. Within three hours the blood was centrifuged for 20 minutes at 2,500 r.p.m. and the plasma pipetted off.

The micro-Kjeldahl determinations and gravimetric estimations were carried out within 24 hours of collection. In the case of the specific gravity method the plasma had been stored for two months at −4°C.

Micro-Kjeldahl Method.—As this method, though often used, is open to a number of fallacies, we propose to describe our procedure in detail.

(i) *Total Nitrogen.*—The method advocated by Peters and van Slyke (1932) is to dilute 1 ml. of the plasma to 10 ml. with 0.9% (w/v) NaCl and then to digest 1 ml. aliquots of the diluted plasma. This procedure, in our opinion, involves unnecessary manipulation and may introduce errors. The procedure adopted was to pipette from a standardized pipette 0.1 ml. of undiluted plasma into the digestion flask and wash it in with 1 ml. of saline. Comparison of this procedure with the dilution method gave substantially the same results. Each sample of plasma was set up in duplicate. To the digestion flask were added 0.5 g. of digestion mixture described by Chibnall, Rees, and Williams (1943) and 2 ml. of conc. A.R. H_2SO_4. In view of the findings of these writers that low N values may be obtained for proteins if the heating is not continued for a number of hours after clearing, as a normal procedure all digestions were carried on four hours after clearing, which normally took place in about half an hour. It may be added that preliminary experiments showed no difference in the results between 2, 4, 8, and 16 hours' heating. "Blank" digestion flasks containing saline, acid, and digestion mixture were set up for each 6 determinations. The liberation of the ammonia was carried out in a Parnas-Wagner type of apparatus. The NH_3 was determined by back-titration of N/100 HCl.

As a check on the apparatus and standard solutions frequent controls, using known amounts of NH_3 as a solution of ammonium sulphate, were carried out. Recoveries of 98 to 102% of theory were always obtained.

The "blank" determinations were approximately 3% of the experimental value. It would appear that this blank is largely due to carriage over of alkali from the distillation flask, as it is little altered if the digestion mixture is omitted from the flask, and becomes negligible if distilled water is substituted for the soda. As a normal procedure a constant measure of 15 ml. of 40% (w/v) NaOH was added to the flask. This stabilized the blank at a maximum value of 0.028 mg. N. All our results are corrected for the blank determination. Any results that did not agree to within 2% were repeated.

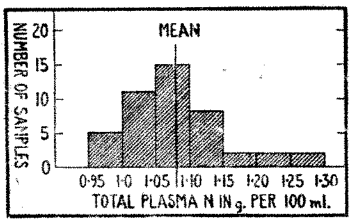
(ii) *Plasma N.P.N.*—This was determined on the Folin-Wu filtrate (see Peters and van Slyke, 1932) in 11 samples of plasma.

Gravimetric Method.—The method used was that of Guillaumin, Wahl, and Laurencin (1929). This procedure involves considerable manipulation and is very laborious. In the series only two of the determinations were carried out in duplicate. Two ml. of plasma was used for each determination. A point that must be strongly emphasized in the gravimetric method is care in drying the coagulated protein to constant weight. This often takes a considerable time.

$CuSO_4$ Method of Phillips et al. (1943).—As an indication of the ease and speed of this method it may be remarked that once the saturated solution of copper sulphate had been prepared the whole procedure of making the separate dilutions and finding the specific gravities of the plasmas took only four hours.

Results

The values for the total plasma nitrogen of the 45 boys are given here in the form of a distribution diagram.



The distribution of total plasma nitrogen in a group of 45 boys.

Taking these figures and multiplying by the factor 6.25 (on the assumption that the protein contained 16% N), the values obtained by the micro-Kjeldahl method are shown in contrast with those obtained by the copper sulphate method (Table I).

TABLE I.—*Total Plasma N, Protein (N×6.25) and Protein as estimated by the $CuSO_4$ Method in the Plasma of 45 Boys aged 14 to 15. N.P.N. in 11 Samples of Plasma is also given : Values as g. per 100 ml.*

	Total Plasma N	Protein (N × 6·25)	Protein by $CuSO_4$ Method
Range ..	0·95–1·26	5·80–7·80	5·50–8·25
Mean ..	1·078 ± 0.14	6·65 ± 0·42	6·97 ± 0·73

N.P.N. (11 samples): Range 0·022–0·033. Mean 0·025 ± 0·0048.

The discrepancy between the values given for N content and those given for protein (i.e., after multiplying N by 6.25) is due to the fact that the latter were obtained from N values taken to one significant place of decimals only. An error of not more than ± 2% may be assumed for the N values. We now regard these values as the more accurate expression of the protein content.

Table II shows a comparison of the results in respect of 12 specimens of plasma in which the proteins were determined by three different methods. It will be seen that collectively the agreement is fairly good, but individually the agreement is far from perfect.

TABLE II.—*Plasma Proteins (g./100 ml.) by Different Methods*

Micro-Kjeldahl (Total N × 5·25)	Gravimetric	$CuSO_4$ Method
7·70	6·30	6·85
7·20	6·23	6·85
6·45	7·05	6·15
6·55	6·84	7·20
6·70	7·46	8·20
6·15	6·19	7·20
6·25	6·13	6·50
6·30	6·56	7·20
6·55	6·00	7·10
7·30	6·75	7·35
7·50	7·39	7·15
7·10	7·24	7·00
Mean 6·81 ± 0·53	6·68 ± 0·48	7·06 ± 0·51

In the Tables ± is the standard deviation calculated by the method of Bradford Hill (1942).

Discussion

One of us has determined the nitrogen content of the acetone-treated heat-coagulated plasma proteins and finds it to be 15.2%. This value gives a protein factor of approximately 6.6 (Cook, 1945). The nitrogen distribution of plasma is so complex that a conversion of any part of it into protein by multiplying by a simple factor is not justifiable. For example, the view that only proteins are precipitated by acid tungstate can easily be shown to be erroneous, because in this precipitate are brought down the N-containing phosphatides. Another important factor is that the N content of globulin and albumin may well be different. Such a state of affairs may explain the individual differences seen in Table II. The whole subject merits reinvestigation. If methods dependent on N determination are used it would be advisable to express results as g. protein N or as g. N precipitated by some particular precipitant—say acid tungstate or trichloracetic acid. For all practical purposes, however, multiplying total N by 6.25 produces a reasonably accurate result and one that is now generally accepted as giving an exact value, even if of the pseudo variety, to the proteins of plasma. It should be stressed, however, that the final court of appeal ought always to be the gravimetric method. Probably on account of its laborious nature this will never be popular.

These experiments also indicate that, for a quick and reasonably accurate method of analysis, determination of the plasma proteins by the specific gravity method is of great value.

Summary

The plasma proteins of 45 boys aged 14 to 15 have been estimated by (*a*) determination of nitrogen by the micro-Kjeldahl method, and (*b*) the $CuSO_4$ specific gravity method. The values obtained are shown in Table I.

In 12 cases the results from the above two methods were compared with those of the gravimetric method. Collectively, agreement between the three methods is good, but there are considerable individual differences.

The gravimetric method is the most accurate. It is considered that if a method dependent on N determination is used the result should be stated as g. N per 100 ml.

As a rapid approximate determination the $CuSO_4$ method is justified.

We are grateful to Dr. W. L Burgess, C B.E., and Prof. R. C. Garry for their interest in this work, and to Mr. H. Macdonald for able technical assistance.

EARLY TREATMENT OF BELL'S PALSY

BY

H. P. PICKERILL, C.B.E., M.S., F.R.A.C.S.

AND

C. M. PICKERILL, M.B., Ch.B.

(From the Plastic Surgery Department, Wellington Hospital, New Zealand)

It is said that 75% of cases of Bell's palsy recover spontaneously, and therein we think lies the cause of lifelong disfigurement for many people. It seems to be always hoped, sometimes presumed, that the particular case in hand is or will be one of the 75, in spite of the fact that there is often no means of knowing if it will turn out to be so. We should regard Bell's palsy rather from the point of view of those who do not recover spontaneously, and say that in 25% of cases the present usual line of treatment results in complete failure and the patient is permanently disfigured ; this is a more arresting point of view, and is likely to result in a considerable diminution of such failures. In every fresh case of Bell's palsy we suggest that it should be assumed not that it will probably get well if little or nothing is done, but that it is possibly one of the 25 which will not recover by itself, and measures should be taken accordingly. That the treatment nowadays of any surgical condition should have so high a failure rate as 25% should of itself call for attention and inquiry. In every case of Bell's palsy the only safe procedure is to presume that it will not recover unless something more than an attitude of masterly expectancy is adopted. We are concerned primarily with cases due to exposure to cold and not with cases due to disease or trauma of the temporal bone or to central causes, though the treatment to be advocated will be beneficial and helpful in all, even when from the start no recovery can be hoped for in such cases as severe intentional or accidental trauma. This paper is not intended to be a dissertation on "facial paralysis," but simply a contribution to assist the general practitioner, for we are convinced that the possibility of reducing the present 25% failures rests in his hands.

Probably the chief factor in non-recovery of what should be the temporarily paralysed muscles is their immediate and continued overstretching by the non-paralysed muscles of the opposite side of the face. A common method of attempting to overcome this is by the use of a hook in the corner of the mouth attached by a loop to the ear; but, as will be shown, this is often worse than useless. A more simple and effective method of restraining the overaction of the muscles of the sound side is by means of strapping. It is applied thus.

The Strapping Method

The lower half of the paralysed side is first smeared thinly with vaseline or oil. Two strips of half- or three-quarter-inch strapping are then applied to the clean sound side on a level with the upper and lower lips, starting about three-quarters of an inch in front of the ear (Figs. 1 and 2). The sound side is pushed across to the paralysed side, and while in this position the other ends of the strapping are firmly stuck down to the mastoid process on the paralysed side (Fig. 3). Good and very adhesive rigid strapping must be used—not elastoplast. The strapping, once on, must be left indefinitely on the sound side. If it is removed the skin becomes sore and there is difficulty in reapplying it firmly; moreover, the patient is discouraged from persisting with the treatment. When it gets soiled another piece may be placed on top of it, and only in some real necessity should it be removed, gently, by the surgeon or nurse, with the aid of a solvent, and reapplied immediately. Non-adhesion to the paralysed side is necessary in order to avoid the possibility of a pull on the paralysed muscles and so that gentle massage may be given; also so that the patient may endeavour to make voluntary movements of the affected side in front of a mirror at the end of a week or ten days. The latter method is probably the most effective that can be employed to aid recovery, but it must be done while the normal side is out of action. That is to say, conditions must be such that the only thing the paralysed orbicularis oris or zygomatic muscles have to do is to respond, even if ever so feebly, to the will to contract; they must not be concerned also with opposing the pull of the muscles of the opposite side. The probable reason why massage and exercises are so often ineffective is that in the early stage of recovery the muscles are overpowered with work by having two jobs to do at once, and, again becoming overstretched, anything gained is soon lost. The paralysed orbicularis oculi muscle should be supported by a sling composed of two quarter-inch strips of strapping running downwards from each end of the eyebrow and meeting below the centre of the lower lid, as shown in Fig. 1. This serves to keep the lid in apposition to the eye, to prevent epiphora, and to counteract the weight of the paralysed cheek and so prevent the orbicular muscle from losing tone. Fortunately this muscle is not concerned with opposing its fellow on the opposite side, and so this method of strapping is nearly always successful in its object; it may be said that if it is applied early enough, and persisted in, there will certainly be no ectropion to follow in simple Bell's palsy.

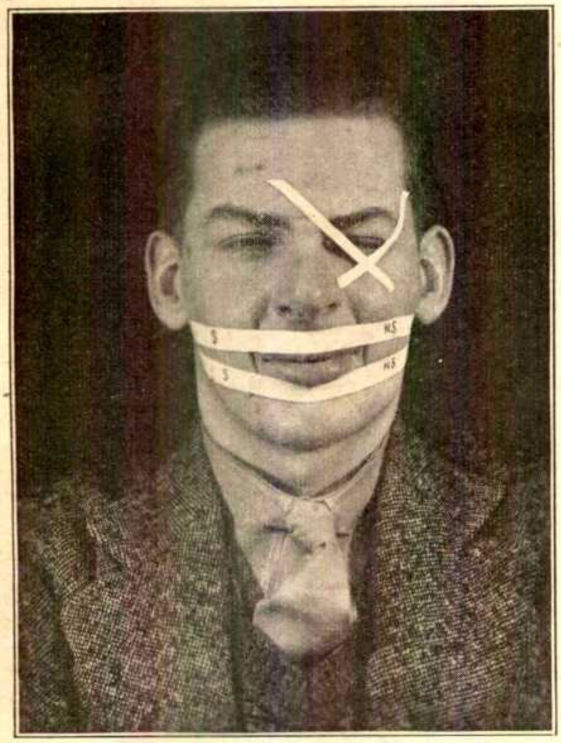

FIG. 1.—Showing method of applying strapping. S=strapping stuck to skin on sound side. N.S.=strapping *not* stuck to skin, on paralysed side. Also showing sling for paralysed orbicularis oculi muscle to prevent ectropion.

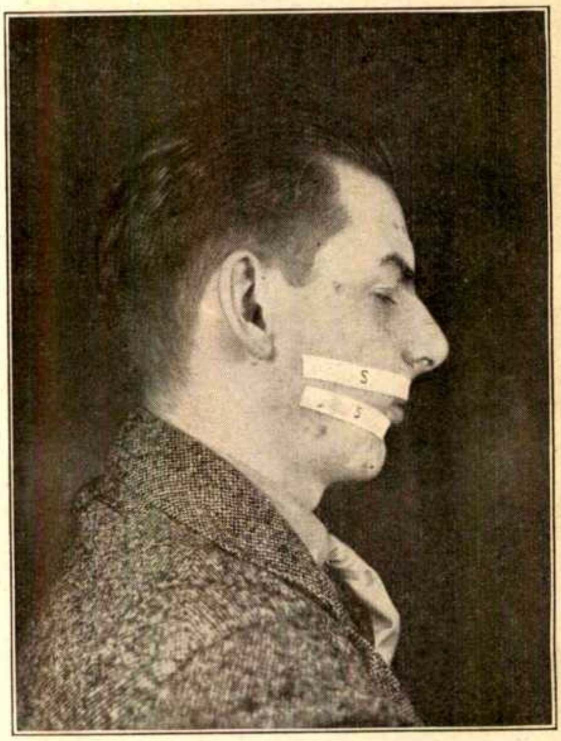

FIG. 2.—The strapping stuck to the skin on the sound side; it should not be carried back further than shown.

Electrical Measures.—During the third week, if recovery is not obvious, the muscles may with advantage be stimulated with weak faradic currents. Minimal doses only should be used—just sufficient to cause visible contractions in the orbicularis and zygomatic muscles. The aim should be just to maintain tone and not to tire the muscle with violent contractions. A current which causes any painful sensation is much too strong, and will do harm. The current should be tried first on the operator himself and then on the sound side of the patient before being applied to the paralysed muscles. If a current which causes contraction on the patient's sound side causes no contraction on the paralysed side, no attempt should be made to produce contraction by using a stronger current. Short daily treatments with very weak current should be ordered. The strapping should be kept on and the above treatment continued indefinitely. It may be for only a week or two, but it may be for two or three months. The patient must be handled very strictly, and be impressed with the serious risk of taking the strapping off even for one occasion, no matter how seemingly important it may be. One laugh without the strapping may undo weeks of treatment, and to leave it off for several days just when recovery is beginning will almost certainly result in partial failure.

The Mouth Hook.—From what has already been said it will be obvious that if the point of decussation of the orbicularis oris muscle on the paralysed side is made a fixed point, then, when the overacting sound fibres contract, the effect on the paralysed fibres will be to stretch them still more—much more than if there were no hook. If the hook is so adjusted that it actually pulls the angle of the mouth back, not only will the stretching be more severe but the fasciculi radiating from it, the depressor and levator anguli oris muscles will be stretched too. The only muscles which the hook really rests are the zygomatics, and in cases in which the hook has been used we often see that these are the only muscles which have recovered, the orbicularis being particularly flaccid. The rule should be, "Look after the sound side—leave the paralysed side alone ; it is the sound side which does the damage."

Other Methods of Treatment

Nerve grafting in traumatic (mastoid) cases is obviously the method of choice and, equally obviously, should be employed early if it is to be successful, as also should decompression of the aquaeductus fallopii if thought necessary ; these operations, however, fall within the sphere of otolaryngology and will not be discussed here.

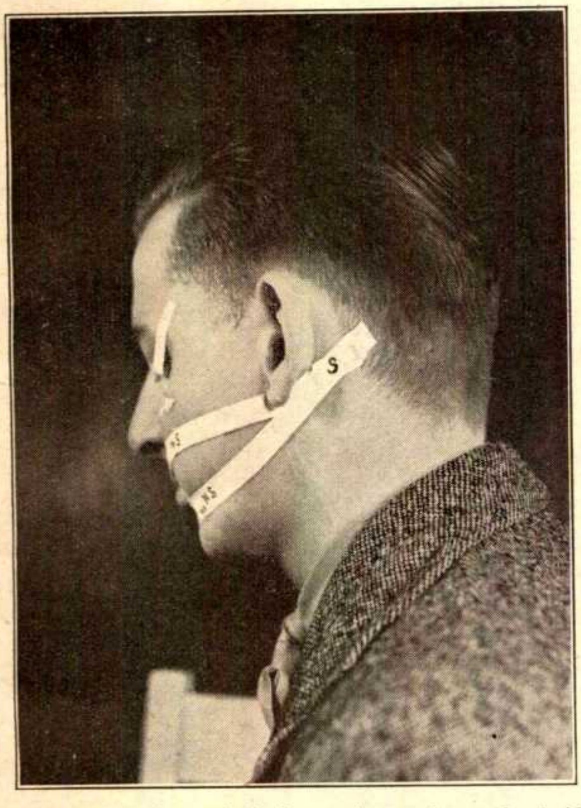

FIG. 3.—Showing method of strapping on the paralysed side. N.S. = Not stuck. S = Stuck very firmly to the mastoid process and a little way beyond the hair line.

Fascia Lata and Muscle Grafts.—These are the plastic surgeon's methods of dealing with facial paralysis in cases usually referred in the later stages, when R.D. is complete. We would, however, like to advance a plea that all traumatic cases (even those few for which nerve grafting is chosen) should be referred to the plastic surgeon as early as possible after the injury. Slings of fascia lata to take the weight of the paralysed cheek, to restrain the overacting muscles of the opposite side, are ideal for the purpose ; they are permanent and invisible, and should be used instead of strapping, which can be regarded as only a "tide-over" method in this class of facial paralysis, but which should nevertheless be adopted *immediately after the trauma,* and replaced as soon as possible by fascia lata. For instance, if the facial nerve is implicated in a parotid tumour and the surgeon judges that it is better to sacrifice the facial nerve and save the patient's life, the strapping described above should be applied at the end of the operation, and the case referred to the plastic surgeon in three weeks' time. There is nothing to be gained by waiting, but much to lose. It is surprising how little tone the muscles seem to lose when they receive early and permanent support in this way. Here as elsewhere it is easier, and the result is infinitely better, when deformity is forestalled than when reliance is placed on correcting it after it is well established. The difference between the results of the same operation (fascia lata grafts) done three weeks after total facial paralysis and three years after is almost incredible to those who have not had the opportunity of such comparison. There is some strange persistent urge to "wait and see" if recovery will take place or whether the paralysis will become bad enough to need operation. The answers to this are: (1) recovery will be hastened and not retarded by the fascia lata operation, which may make recovery possible in some cases where it would otherwise be impossible ; (2) if nothing is done in the case of total paralysis it is *certain* to become bad enough to require operation, and the golden opportunity of obtaining the best result has been lost.

In well-established long-standing cases (which in future we think should not be permitted to exist) the choice lies between (1) fascia lata slings for the orbicular muscles, and perhaps temporal and masseter muscle slips to give some voluntary movement after re-education, and (2) anastomosis with the hypoglossal nerve. The former methods give balance to the face, with a little muscular movement of the angle of the mouth and full closure of the eye ; while the latter method, when successful, provides mass movements only, and facial balance in repose is not often so good as in the sling method.

OSTEOMYELITIS OF THE SKULL DUE TO SALMONELLA TYPHI

BY

J. M. LEVER, M.B., Ch.B.
Clinical Pathologist, Atkinson Morley Emergency Hospital

AND

G. B. BARKER, M.R.C.S., L.R.C.P.
First Assistant, Neurosurgical Unit, Atkinson Morley Emergency Hospital

Cases of osteomyelitis due to the typhoid bacillus are uncommon ; the following case is also of interest owing to the great length of time that elapsed between the initial infection and the occurrence of osteomyelitis, the site of infection, and mode of onset of the condition.

Case History

A man aged 40, a linesman on the L.P.T.B., was admitted to this hospital with a history of headaches for two years. These had occurred almost daily, and were of a stabbing character lasting varying times from one hour to a whole day. They did not interfere with his work ; he had accepted them as part of his life and did not seek medical advice.

For the three months before admission they had been getting steadily worse ; he had been losing sleep and was beginning to feel weak and exhausted. On Dec. 24, 1944, he was sitting in his kitchen when he felt a tingling sensation in his right hand. He rose from his chair and found that he had lost control of his right leg, which was useless. This attack lasted one hour and then passed off, leaving him apparently normal in every respect. He consulted his doctor and was admitted to hospital, where he had a similar attack. Investigations proved negative and he was discharged. He still lacked energy, however, and the headaches had increased in severity. Shortly after this he had a severe pain in the back of the head, agonizing in nature ; he consulted his doctor, who found a soft fluctuant swelling in the occipital region, and he was again admitted to hospital.

During the next four days the swelling increased steadily in size, but the severe pain passed off, to be replaced by a dull ache. On admission to us, 10 days later, he had a soft, diffuse, smooth, very tender, hot swelling 2½ in. in diameter over his occipital region, mainly on the right side, and considerable oedema of the surrounding overlying scalp. This was a typical Pott's puffy tumour, and in addition he showed early papilloedema, a slight facial palsy of upper motor neurone type, and increased reflexes in the right arm and leg.

Radiographs of the skull showed definite osteomyelitis, with a roughly circular defect 1½ cm. in diameter lying over the midline in the occipital region and extending to the left in the post-parietal area. In addition there were a number of other small scattered areas of rarefaction on the right side in the mid-parietal region, and a number of small sequestra could be seen. The pineal lay in the midline and the accessory sinuses and mastoids were clear.

Operation.—On turning back skin flaps over the swelling a large quantity of thin, brownish pus escaped. On exposing the bone thick areas of granulation tissue were seen, particularly on the left side, and just to the left of the midline was a small opening in the bone through which pus was pouring. The infected bone was nibbled away, to reveal a large extradural abscess and the dura covered with thick granulation tissue. All infected bone was removed and the granulation tissue scraped off ; the dura was not opened. The wound was filled with hydrogen peroxide, powdered with sulphanilamide, lined with gutta-percha, and packed. The patient's condition deteriorated slightly during operation, but not appreciably.

He was put on a post-operative course of succinyl sulphathiazole 2 g. four-hourly, and blood estimations next day showed a sulphonamide level of total 3.38 and free 2.02 mg. per 100 c.cm. His further course was smooth and uneventful.

The following bacteriological investigations were carried out:

March 21.—Pus aspirated from swelling ; direct smear—no organisms seen ; culture (horse-blood agar) yielded growth of "coliform bacilli" only. Urine: test for Bence-Jones's protein, negative ; no albumin present.

March 26.—Swab (operation) culture (blood agar), pure growth of "coliform bacilli" ; a penicillin-sensitivity test (cylinder-plate method) gave no inhibition of growth. At the request of Mr. McKissock further investigations were carried out to identify the organism, and the usual routine sugar tests gave the following results: Production of acid only with glucose, mannitol, and dulcitol ; no fermentation of lactose or saccharose. The organism was a Gram-negative motile bacillus, did not give a positive indole reaction, and did not liquefy gelatin. This pointed to *B. typhosus.* An agglutination test of the suspension of the organism with standard agglutination sera of *B. typhosus* H and *B. typhosus* O did not give definite agglutination to standard titre. It was therefore decided to send a culture to the Lister Institute at Elstree for confirmation

March 27.—Patient's serum agglutinated with standard suspensions of *B. typhosus* H and O. Agglutination with *B. typhosus* H to titre of 1 in 80. *B. typhosus* O no agglutination. B.S.R.: 1st hour, 65 mm.; 2nd hour, 105 mm. Hb, 54%; R.B.C., 3,400,000; W.B.C., 1,400 (polys 90%, lymphs 8%, monos 2%).

March 31.—Swab taken from wound at the first dressing showed no organisms in direct smear and no growth on culture. The wound was granulating slowly and the condition of the patient was excellent.

April 9.—Wound swab yielded on culture a few colonies which in suspension now gave positive agglutination with standard agglutinating serum : *B. typhosus* H, *B. typhosus* (Vi). No agglutination with serum *B. typhosus* O.

April 11.—Report from the Curator of the National Collection of Type Cultures, Lister Institute, confirms the biochemical findings, with these additions: "It gives acid but not clot in litmus milk and does not give a positive carbinol reaction ; it also gives a positive O agglutination with typhoid antiserum. Taking these findings as a whole, I think there is little doubt that this Salmonella is indeed *Salmonella typhi.*"

Subsequent investigations on samples of duodenal contents, urine, and faeces failed to isolate *B. typhosus* on three occasions, and cholecystography showed a normal gall-bladder.

Discussion

In view of the very great rarity of osteomyelitis due to *B. typhosus* (Murphy (1916) quotes three instances in 700 cases) the true nature of the "coliform bacilli" isolated from the aspirated pus and from the field of the operation was not suspected. "Coliforms" are a frequent causative organism of osteomyelitis either alone or in conjunction with other organisms, and no significance was at first attached to this. The request for fuller identification with the resultant biochemical reactions opened up further inquiry into the patient's history. He then disclosed an attack of enteric fever at the age of 7—he is now in his 41st year. He had previously not mentioned this illness, nor had it been recorded ; though, even so, after the very long interval of time it most probably would have been considered of no significance. On inquiry at the hospital concerned no documentary corroboration could be obtained—all the papers of so remote a period had been consigned to "war salvage—but it was stated that at that period routine bacteriological and serological tests would most certainly have been done to confirm the clinical diagnosis.

His subsequent illnesses were malaria in 1927 and a further relapse in 1929 during military service. There is a record in his pay-book of two injections of T.A.B., on Nov. 23 and 30, 1927 : no dosage was mentioned. These do not appear to have succeeded in completely ridding him of his carrier state. He had been entirely free from illness from 1929 until his attacks of headaches two years ago as described above. There can be no doubt that he has harboured *B. typhosus* for 33 years.

Of great significance is the history given by the patient of repeated injuries to his head sustained while working in a low room. He had definite recollection of such injury, over approximately the site of the subsequent abscess, on at least six occasions during the past few years, although on no occasion was the injury severe enough to render him unconscious.

This association of localized injury and subsequent typhoid abscess formation is a very frequent feature in cases in which an acute focus of infection has appeared after a long interval of time in the typhoid carrier. This is borne out by the following cases reported in the literature. Van Dyke (1933) described a case of typhoid osteomyelitis of the femur occurring 24 years after the original attack of typhoid fever—the precipitating cause being a kick on the thigh from a horse. Wardle (1935) describes a case of Brodie's abscess of the tibia occurring 10 years after an attack of typhoid fever. Here again there is a definite history of injury to the shin. There is also quoted from Keen's *Surgical Complications and Sequelae of Typhoid* a case reported by Buschke in which a pure culture of *B. typhosus* was obtained from a tibial abscess 7 years after the fever, the condition having been precipitated by injury. The points of interest in these cases are the length of time elapsing between the attack of typhoid fever and the formation of localized osteomyelitis from which *B. typhosus* was recovered in pure culture—in our case 33 years. It is interesting to speculate as to the precise lair wherein the organisms are lying in wait during these years. A search of the faeces, urine, and duodenal contents failed to isolate them. And what particular part does trauma play in initiating the morbid processes leading to local settlement of *B. typhosus,* resulting in the formation of a localized abscess ? A further point of interest is that we have been unable to find in the literature any previous cases of osteomyelitis of the skull giving pure culture of *B. typhosus.*

Summary

A case of osteomyelitis of the skull is described with full bacteriological investigations, in which the infecting organism was found to be *B. typhosus* occurring 33 years after the original infection.

This case demonstrates the importance of not omitting any illness of childhood from the records of previous illnesses, the very long interval of time after the original fever that can elapse in pyogenic conditions due to *B. typhosus,* and the surprising results which may on occasion arise from more intimate identification of "coliform bacilli" isolated from localized septic conditions.

Our thanks are due to Mr. McKissock for permission to publish this paper and to the Curator of the Lister Institute of Type Cultures, Elstree, for his co-operation. Also to Dr. Lyle for his help in taking the history and clinical examination, and to Mr. Ellis, laboratory technician.

The Scientific Films Committee of the Association of Scientific Workers has now revised and printed its catalogue of scientific films. A grading system shows the suitability of each film for various types of audience. This catalogue can be bought for 2s. 6d. from the head office of the A.S.W. at Hanover House, 73, High Holborn, London, W.C.1. The Scientific Films Committee was set up in 1938 with the object of furthering the interests of the scientific documentary film, encouraging the making of more such films, and sponsoring the exhibition of scientific films.

Medical Memoranda

Aetiology of Pancreatic Apoplexy

Acute haemorrhagic pancreatitis is usually due to a fulminating infection which either gives rise directly to a haemorrhagic exudate or does so indirectly by the liberation of pancreatic ferments which destroy the walls of the small blood vessels. A few cases, however, of so-called pancreatic apoplexy appear to originate with massive haemorrhage, and the following report throws light on the pathogenesis. The necropsy was one of three similar necropsies seen by me in the last 20 years.

Pathological Report on a Case

A housewife aged 52 (Case No. 179480) was admitted to the City General Hospital, Sheffield, suffering from acute pancreatitis of 10 hours' duration, and she died 26 hours later.

Post-mortem Examination, Feb. 26, 1945 (relevant details only).—The body was that of a very obese female. The peritoneal cavity was full of blood-stained fluid, and the omentum and mesentery were diffusely spotted with fat necrosis. The body and tail of the pancreas were diffusely infiltrated with blood and there was considerable retroperitoneal clot in the left perirenal region. The head and neck of the pancreas were diffusely suffused with blood in their posterior portion, but the anterior parts were only slightly affected, though blood clot surrounded the entire organ. The spleen appeared normal, though surrounded by blood clot, and on dissection it was evident that the haemorrhage had originated in a rupture of the inferior of two large splenic veins before they united to form the main splenic vein about 4 in. from the hilum of the spleen. There was cholesterosis of the gall-bladder, but no calculi or other abnormalities were found in the biliary or pancreatic ducts. No fat necrosis was present in the thorax.

Comment

These three cases all suggest that the primary lesion in the final catastrophe was haemorrhage from rupture of a splenic vein, and that the effused blood injured the pancreas, leading to secondary autolytic digestion, etc., in the region. That the process is not in the reverse direction is suggested from observations on other necropsies of the same condition, which are of primary autolytic or infective origin and which never, so far as I know, lead to the opening of the wall of a large blood vessel. It may be that the initial process is a mild inflammation which produces adhesions between the usually mobile splenic veins and the pancreas, and that some movement may precipitate the final rupture, but I am unable to adduce any proof of this.

A Case of Achalasia of the Cardia

In a typical case of achalasia of the cardia the symptoms are accompanied by radiological evidence of enlargement of the oesophagus. It is uncertain, however, whether the enlargement follows the onset of symptoms or whether the sequence of events is reversed. The case described below throws light on this point because enlargement of the oesophagus followed the onset of symptoms.

Case History

Mrs. A., aged 59, a housewife, was admitted to hospital on April 5, 1944, with a history of dysphagia and bouts of vomiting since Oct., 1940. She dated the symptoms from the time when her house was bombed. She had lost 34 lb. in weight and her appetite was poor; her diet consisted mainly of soft foods, including milk. There were no abnormal signs on physical examination. The vomitus contained no free hydrochloric acid.

Her oesophagus was *x*-rayed in Oct., 1941, a year after the onset of dysphagia, and was found to be normal. About the same time Mr. F. C. Ormerod examined it endoscopically with the same result. In April, 1942, radiography of the oesophagus showed that no barium passed into the stomach for five minutes and that there was a fusiform dilatation of the oesophagus. These radiological findings were confirmed in April, 1944, the dilatation being somewhat greater than two years previously.

Commentary

The following conclusions can be drawn from this case. (i) Achalasia was probably present for a year before the patient was first investigated in 1941, and yet the oesophagus appeared normal to clinical test. (ii) Definite oesophageal dilatation occurred quite rapidly over a period of six months (Oct., 1941, to April, 1942).

Hurst and Rake (1929–30) have set out in detail their view of the manner in which the oesophageal enlargement comes about. It may be summarized as follows. (*a*) As a result of inflammation of Auerbach's plexus in the region of the cardia, the neuromuscular mechanism is upset and a functional obstruction to the transfer of material from the oesophagus to the stomach is produced. (*b*) The obstruction becomes progressively worse, but for a time hypertrophy of the circular muscle fibres of the oesophagus "compensates" for the obstruction. (*c*) Finally, further compensation can no longer occur and the oesophagus enlarges. In very advanced cases it may also lengthen.

There is a good deal of evidence to support this hypothesis. Many cases with clinical and radiological evidence of achalasia of the cardia show, post mortem, few or no ganglion cells in Auerbach's plexus in the region of the cardia (cf. Rake, 1927). Hurst and Rake (1929–30, p. 499) refer to three cases in which the wall of the oesophagus was found at necropsy to be hypertrophied though the lumen was of normal size, and in which the changes referred to above were present in Auerbach's plexus. This lesion of the oesophagus was symptomless and was thought to represent the stage of "compensation." Hurst (1943) records a case (Case 4, p. 70) in which the dilated oesophagus in the course of a few years became S-shaped, so that the patient could no longer use a mercury bougie.

The missing link in this chain of evidence was the demonstration that an oesophagus with a lumen of normal size could enlarge. Bockus (1943) has described this change, though oesophagitis with ulceration of the mucosa in the region of the cardia complicated his case. The present case shows that the enlargement can occur in an organ which appears normal radiographically and endoscopically.

We wish to thank Dr. C. M. Hinds Howell for permission to publish this case, and Mr. F. C. Ormerod for letting us use his endoscopic observations.

Neurological Complications in Tropical Macrocytic Anaemia

In view of the statements made by several authorities (Wills, Clutterbuck, and Evans, 1937; Trowell, 1943), that nervous symptoms and subacute combined degeneration have never been found in nutritional macrocytic anaemia, a report of the following case may prove interesting.

Case Record

A coloured woman aged 22 was admitted to the Belize Hospital on Feb. 2, 1943. At the time of admission she was in the seventh month of pregnancy. Her illness had begun three months previously with an attack of fever, which was followed by the onset of numbness in her hands and feet and a sensation of tightness around the waist. Trembling and weakness ensued whenever she tried to stand up, and gradually she lost the ability to walk. Temperature 99° F. on admission. The fundus of the uterus was felt 2 in. above the umbilicus. On examination there was marked loss of power in the upper and lower limbs. Sensation for pain and touch was diminished on the inner aspects of both legs, and there was considerable impairment of the sense of position in the upper limbs and in the left leg. The abdominal reflexes and knee- and ankle-jerks were all absent, and no plantar response could be elicited. Physical examination was otherwise negative. Urine: trace of albumin. Stool: no ova. Blood count: red cells, 2,810,000 per c.mm.; Hb, 68% (Dare), or 11 g. per 100 c.cm.; C.I. (corrected to Haldane), 1.4; M.C.V., 128.5 c.μ; M.C.H.C., 35.5%; white cells, 5,400 (no differential count done); icterus index, 5. Alcohol–histamine test meal: free HCl present. Kahn reaction, negative. Treatment consisted of 6 c.cm. of anahaemin (B.D.H.) during the first week, followed by 18 c.cm. of liver extract (Lilly) during the next three weeks. On March 18 a blood count showed: red cells, 2,730,000 (reticulocytes 3%); Hb, 70% (11.2 g.); C.I., 1.5; M.C.V., 118.5 c.μ; M.C.H.C., 35%; white cells, 7,240. Subsequent treatment consisted of 7 c.cm. of liver extract weekly, acid. hydrochlor. dil. m. 10 t.d.s., and thiamine 9 mg. daily, up to the time of delivery on April 11. The patient's mental attitude during this period became more cheerful, and she said she felt stronger, but no demonstrable improvement in her neurological condition could be detected until she gave birth to a somewhat premature baby weighing 5 lb. After that time her symptoms improved rapidly, and by the end of a month she was able to walk. When last seen, in Nov., 1944, she was in good health, and there had been no recurrence of her nervous symptoms.

Reviews

PENICILLIN THERAPY

Penicillin Therapy, Including Tyrothricin and Other Antibiotic Therapy. By John A. Kolmer, M.S., M.D., F.A.C.P. (Pp. 302. 25s.) London: D. Appleton-Century Company. 1945.

It was to be expected that the now enormous literature on penicillin would soon undergo condensation into book form, and the first product of this process which we have received is *Penicillin Therapy* by John A. Kolmer. This handy volume not only is a trustworthy practical guide to treatment, but deals equally thoroughly with the laboratory and purely theoretical aspects of the subject. There are very full instructions about methods of administration, not omitting the numerous forms of local application and devices by which systemic effect may be prolonged. In the purely clinical section, disease is classified aetiologically—the only rational system in dealing with a chemotherapeutic agent so selective in its action—and the importance of a bacteriological diagnosis and laboratory control generally is emphasized.

Apart from those conditions in which the therapeutic efficacy of penicillin is fully established, there are many references to others in which the indications are not so clear, and very full lists of micro-organisms divided into three categories according to their susceptibility. The author is perhaps a little unduly pessimistic about the treatment of actinomycosis, and *H. pertussis* and the Morax-Axenfeld bacillus deserve promotion from the third to the second category ("moderately susceptible"). There is also a chapter on other chemotherapeutic agents of microbic origin, dealing chiefly with tyrothricin, and one on the use of penicillin and tyrothricin in dentistry and oral surgery. The text is fully documented, with lists of references at the end of each chapter. Although there is an appendix evidently dealing with developments after the main text was written, the whole book is remarkably up to date, and the author is to be congratulated on producing so serviceable an epitome of the whole subject at this stage of its evolution.

UNCOMMON SENSE ABOUT COMMON FOODS

Cooking and Nutritive Value. By A. Barbara Callow, M.A., M.Sc. (Pp. 156. 7s. 6d.) London: Oxford University Press. 1945.

As the family physician comes more and more to be consulted on matters of diet, in health as well as in disease, so he will need increasingly to be able to lay his hand on sources of information that are balanced and up to date. He will wish to avoid those authors that look down their academic noses at every old wives' tale not yet submitted to the searching critique of laboratory test; he will equally desire to shun those purveyors of dogmatism and obscurantism who seem to think that they have supplied the final justification for a food material or a dietary habit if they have called the one living and the other natural. He will know that the practical nutritionist—at any rate, the nutritionist who can help him in his daily task—is one who steers a sane middle course between the Scylla of scepticism and the Charybdis of obfuscation. In Mrs. Callow's book he will find abundant evidence that she is just such a practical nutritionist. She writes with simplicity and clarity, enlivened by occasional touches of humour; her account of modern views about the composition and nutritive value of foods before and after cooking and processing—for that is what her book is about, although the title may suggest a somewhat narrower delimitation of the subject—is as accurate as any one writer can make matters that have been investigated by a large number of specialists. Her book deals, in separate chapters, with meat (including poultry and game); fish; vegetables; fruit and nuts; milk, butter, and cheese; eggs; and cereals, following an introductory chapter on "The Nutritive Value of Food." A short literature list at the end gives some 70 references: it is significant, and not merely an indication of local university patriotism, that McCance and his colleagues are responsible for seven of these—easily the largest single score. Mrs. Callow's other references are of the same order of authority. The back end-paper and the inside back cover give respectively a comparative table of British and decimal weights and measures and a diagram for conversion of degrees centigrade to Fahrenheit.

In a book of this kind there must inevitably be statements to which some reviewer or other will take exception, for the element of personal judgment still enters to no small extent into many of the findings of modern nutritional science. Examples here are the inclusion of cod-liver oil (p. 50) as a rich source of iodine, when many of the very best oils, potent in vitamins A and D, contain none at all, and when none is required by any pharmacopoeial standard; again, the attribution to wheat of any vitamin A activity (p. 132) is not consonant with the findings of Zechmeister and others, who have shown the wheat carotenoids to be biologically inert. A review, however, is no place for the enumeration of critical minutiae, which are better communicated direct to the author. Especially is this so when, as here, the reader often finds his criticism forestalled by the author within a few lines of the passage that gave rise to it.

Although this book is intended primarily for the non-specialist, Mrs. Callow has wisely thought well, right at the beginning, to indicate the shape of modern views about the fluid nature of the body's amino-acid stores; one can also whole-heartedly welcome her insistence that statements about the nutrient contents of a food are of little value without consideration of the quantities of that food likely to be consumed. Valuable also is her objective account of the nutritional differences between flours of different extraction.

When this book goes into the later editions that it deserves and will doubtless get, Mrs. Callow might perhaps consider slightly modifying certain of her presentations. For instance, the low nicotinic acid content of maize can no longer be held solely—or even mainly—responsible for its pellagragenic nature, now that we know milk and whole wheat—recognized anti-pellagric foods—to contain little if any more of the vitamin than maize. Again, various statements about the "gains" in energy value of foods after frying could be clarified by relating these gains with the increases in weight due to the absorption of fat. Further points of comment arise from her reference to the value of wheat offals for ruminants: it might be wise to remember H. D. Kay's remark that the cow "would not care a whisk of her tail" if she never tasted bran again, and to note that it is pigs and poultry, rather than milch cattle, that compete with man for part of the wheat grain. It might also be well to lay rather more stress on the part played by the intestinal flora in supplying essential nutrients to man and other animals, though it is realized that much of the work bearing on this has only been published since the time when Mrs. Callow must have completed her manuscript. The matter may not seem immediately germane to the subject of her book, but it is of importance for two reasons at least: first, as a warning against too glib interpretations of many clinical and laboratory findings; secondly, as offering a possible explanation of certain nutritional deadlocks hitherto unresolved. The maize-pellagra paradox is a case in point.

Mrs. Callow would no doubt be the first to insist that her book makes no new contribution to scientific knowledge, but it does something just as important, and sometimes much more difficult. As a survey in a short space of what is known over a wide and varied field, in which the data are often confused and seldom easy to find, it is perhaps the best book on its subject in the English language, notwithstanding the existence of a number of excellent publications from the U.S.A. which cover similar ground. Furthermore, apart from the information Mrs. Callow has succeeded in presenting on food values, her book contains many useful "tips" on such diverse subjects as the gelling of jams and the splitting of herrings. Its price may at first sight seem a little out of proportion to its size: when one has had an opportunity of studying its contents in detail one realizes that it is a bargain.

PHYSIOTHERAPY

Physical Treatment by Movement, Manipulation and Massage. By James B. Mennell, M.D. Fifth edition. (Pp. 512; illustrated. 30s.) London: J. and A. Churchill. 1945.

The present reviewer, who had the privilege of reviewing the fourth edition of this book in 1940, notices with pleasure that this fifth edition comes out almost in the 20th year since the original production. That it is still produced by the same author after all these years is a remarkable tribute to Dr. Mennell and to the value of the book. It follows very largely the lines of the previous editions, after due allowance has been made for the change forced upon him by the restrictions of war publishing.

In Dr. Mennell's preface to the present edition he draws attention to his Chapter 39, which he calls his "Postscript," and apologizes for the omission in previous editions of any specific reference to the treatment of "tennis elbow." He has, however, made up for previous omissions by a delightful survey of the variety of conditions that can give rise to the painful joint commonly called "tennis elbow." He has a facility for impressing upon his readers care and detail in any technique, thereby imparting to them a sense of confidence in his powers of differential diagnosis and treatment.

In his discussion of the diseases of the central nervous system, including infantile paralysis, sutured motor nerves, and conditions of peripheral nerves, no reference is made to the now generally accepted work and implications of Guttmann and Gutmann, and of the practical and clinical support given to these findings by Prof. Seddon and Dr. Bowden and their team of co-workers at the Peripheral Nerve Injury Centre at Headington, Oxford. The author's comment on the relative value of Sister Kenny's and Mrs. Guthrie-Smith's contributions in the treatment of paralysis and debilitated muscles is worth quoting in full:

> "It yet remains to be proved whether the introduction of Mrs. Guthrie-Smith's sling apparatus will prove to be the really great advance in the treatment of flaccid paralysis as a whole. Personally I have very high hopes, and proof should not be long delayed. For what it is worth, my own opinion is that Mrs. Guthrie-Smith's contribution to the subject far transcends that of Sister Kenny."

This book has so much of genuine value to general practitioner, consultant, and physiotherapist alike that one could wish that Dr. Mennell, with all his years of experience, should now edit a book on physical medicine—using this term in its wider sense.

NEISSER ON SYPHILOLOGY

On Modern Syphilotherapy. With Particular Reference to Salvarsan. By Albert Neisser. Translated by Isabelle von Sazenhofen Wartenberg. Biography and bibliography by F. T. Gardner. (Pp. 42. $1.00.) Baltimore: The Johns Hopkins Press. 1945.

This little volume, besides a translation of a discourse by Neisser on modern syphilotherapy, contains a short biography and an extensive bibliography of this famous syphilologist. The address is well worth study; written in 1911, much of it is as true to-day as it was more than 30 years ago. Neisser must have been one of the first to insist that one injection of salvarsan was not enough, that multiple injections must be given, that mercury should be used concurrently, and that treatment should be continued over long periods; he insisted that Wassermann tests should not be done in small numbers by all and sundry, but must be performed by experienced workers and in large batches if errors were to be avoided. (Would that his teachings were observed more nowadays!) He it was who insisted that the earlier the treatment the greater the chance of cure, that in the early stages the blood reaction could be reversed more easily than in the late, that it is dangerous to rely on a single negative serum reaction, and that spirochaetes may persist in inaccessible situations or assume relatively invulnerable forms.

The modern syphilologist will do well to study this booklet, for not only is it of historic interest but it contains many pearls of wisdom.

The Health Services in Austria: Problems of Medical Reconstruction and Rehabilitation is a group of essays collected by the Committee for Post-War Medical Relief in Austria and the Association of Austrian Doctors in Great Britain. It can be had for 3s. from 14, Craven House, 121, Kingsway, W.C.2. A preface by Prof. F. Silberstein is followed by articles on the past and future of the health services in Austria, on maternity and child welfare, and on dental services, organization of the medical services in liberated Austria, rehabilitation and welfare for the disabled, post-war neurology and psychiatry, and a proposed campaign against venereal diseases in post-war Austria. Opposite the title page is the welcome announcement that the Vienna Allgemeines Krankenhaus had been saved from Nazi destruction by partisan groups consisting of doctors, medical students, and hospital staff.

Preparations and Appliances

A SIMPLIFIED METHOD OF APPLYING THE THOMAS SPLINT

Major LIPMANN KESSEL, R.A.M.C., writes:

The method of applying a Thomas splint for use as a first-aid measure for an injury of the lower limb is described with the diagrams below. It was developed in a parachute field ambulance and was used by some of the medical orderlies of the field ambulance in Europe. The method would appear to be of some value in first aid under any conditions, and may be considered as an alternative in the teaching of first-aiders to replace the present elaborate method of applying a Thomas splint which is taught in both military and civil spheres.

The method is very simple and I had no difficulty in teaching it to men in a field ambulance in a single class of an hour's duration. It is far more difficult to describe the procedure in a paper than it is to demonstrate it in practice. The essence of the method is to leave the injured limb at rest during most of the manipulation by using the material of the trousers from the injured leg rather than the various triangular cotton and flannel bandages now employed.

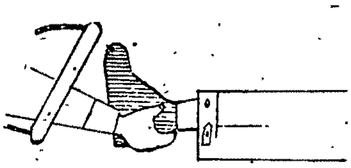

Fig. 1

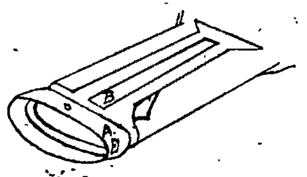

Fig. 2.

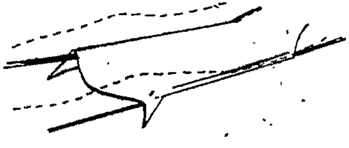

Fig. 3.

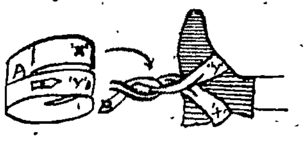

Fig. 4.

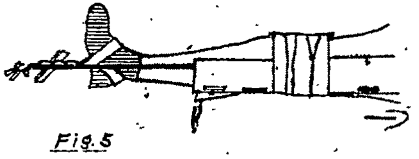

Fig. 5

FIG. 1.—The assistant puts his hand through the ring of the splint, grasps the heel of the injured limb, and exerts steady traction throughout, holding the limb about 6 in. off the ground.

FIG. 2.—The splint is run up to the tuber ischii, and the trouser-leg is pulled well down. A 4-in. cuff is cut off the bottom of the trouser (A), and a strip of material 2 in. wide is cut from the midline anteriorly. The proximal end of the cut is extended to each side as shown (B).

FIG. 3.—The two pieces of material A and B (see Fig. 2) are laid aside, and the cut edges of the trouser-leg are swung round the limbs of the Thomas splint, pulled taut, and fixed together by safety pins behind the limb.

FIG. 4.—The cuff (A) is divided through half its length, and the two "lips" so formed are slipped over the boot, one over the heel and the other over the toe, and twisted several times to stop slipping off the boot. It is fixed to the end of the splint by the 2-in. strip (B).

FIG. 5.—Extension is increased by the usual "Spanish windlass," and a circular dressing is applied above the knee to include the splint. The same dressing may often be used to cover any wound in the area.

The advantages of the procedure are: (1) The injured limb is kept extended and at rest during the procedure, with obvious comfort to the patient and minimized danger from shock and haemorrhage in severe cases. (2) Two men only can easily apply the splint. Only one of these needs to have special knowledge of the method. In the procedure taught at present, three or four trained men are required. (3) The time taken to apply the splint is 3 to 5 minutes. It is doubtful if a splint can be applied in less than ten minutes by the usual method. (4) The materials required, in addition to the Thomas splint and any dressings for an open wound, are a pair of scissors and four safety pins.

The disadvantages of the proposed method are: (1) "Boot-traction" is definitely dangerous, and will cause pressure-sores on the dorsum of the foot if maintained for too long. (2) It is less stable than the usual method, but this can be improved upon by applying the footpiece and further immobilizing bandages at any time after the splint has been applied. (3) The method cannot be considered as anything other than a short-term first-aid measure.

I am greatly indebted to Pte. E. F. Mumford, R.A.M.C., for his illustrative sketches.

MODE OF ACTION OF PENICILLIN

Penicillin is a remarkable substance with a hold on the popular imagination which even the atomic bomb has failed to loosen. We are, however, very little further towards understanding its mode of action than we were when Fleming published his original discovery 16 years ago. Penicillin has an amazing specificity, being intensely toxic for certain bacterial cells and almost without effect on those of animals. Though its specificity is rather like that of the sulphonamides, its mode of action is different. For example, it is not antagonized by *p*-aminobenzoic acid, peptones, or pus; the sulphonamides are. Further, penicillin can prevent the growth of sulphonamide-resistant organisms, and the sulphonamides can inhibit the growth of penicillin-fast strains; and, whereas the sulphonamides act principally by slowing down the rate of growth, penicillin can cause rapid death and lysis of susceptible micro-organisms. Although Fleming's original observation was that penicillin lysed bacteria, early workers[1] on its mode of action emphasized that it was essentially bacteriostatic. Lately, however, its bactericidal and lytic properties have been widely recognized, and Chain[2] even doubts whether penicillin is ever bacteriostatic. It is generally held that penicillin has three phases to its action. It may be bacteriostatic, bactericidal, or lytic, according to conditions. Very small amounts, down to one-tenth of the bacteriostatic dose, may cause pronounced morphological changes.[3] Cocci swell to a great size, and bacilli elongate to many times their length. Penicillin is here interfering with the power of the bacteria to divide, and its action would appear to be bacteriostatic.

The assay of penicillin is based on its bacteriostatic action—that is, on the amount which prevents the growth of staphylococci. Sulphonamides help this action,[4] and the presence of even two parts in a million of sulphathiazole markedly increases the apparent titre of penicillin.[5] On the other hand, sulphonamides interfere with its killing and lytic actions. Garrod[6] found that sulphathiazole halved the rate of disinfection of staphylococci by penicillin. This may mean that the "static" and "cidal" actions are different, though it seems more logical to assume that they are different degrees of the same action. Bacteriostasis is a loose term, since a stationary population may result from inhibition of growth or from the killing of a fraction of each new generation. The powerful killing and lytic actions are exercised only against dividing bacteria, as Todd,[7] Knox,[8] and Chain and Duthie[2] have demonstrated in investigating the effect of penicillin at different growth phases of the staphylococcus. Chain and Duthie showed that if it is added during the early lag phase the total number of bacteria remains constant for three hours, with a greatly increased turbidity and a decrease in the number of viable organisms. This is due to the production of enlarged forms and to a gradual killing without lysis. If the drug is added at the logarithmic phase of growth when division is rapid it causes a rapid diminution of total and viable bacteria by death and lysis. They found that penicillin becomes effective after a ten-minute lag period, and they assume that this is the time required for one division of the cocci, which having divided are rapidly lysed. When added to an older culture which has reached the stationary phase of growth penicillin does not lyse the culture or affect its respiration. Conditions which increase the rate of division—optimal temperature, use of young cells, or rich medium[7]—all increase the rate of killing and lysis. Conversely, lowering the temperature, dilution of the medium, or presence of growth inhibitors like sulphonamides or boric acid[9] or helvolic acid[2] decrease the killing power.

Penicillin-resistant bacteria are important in considering the mode of action. First, there are the naturally resistant species of bacteria, such as the anaerobic spore bearers, which owe their resistance to their possession of penicillinase, an enzyme which destroys penicillin. A small proportion of the normally sensitive species—for example, staphylococci—are also resistant[10] and also secrete penicillinase. The power of the bacteria to divide is an important factor in resistance, because any strain with an impaired power of division will be classed as penicillin-resistant. Resistant strains may be obtained by subculturing sensitive organisms in broth containing penicillin. The resistant strain so obtained has lost its virulence; it is more easily killed by the body mechanisms[11]; it grows very much more slowly than the parent strain, and it does not secrete penicillinase.[12] It can withstand up to 3,000 times the concentration of drug tolerated by the parent strain.[13] The resistance is only temporary, and after a few cultures in drug-free broth it becomes sensitive and recovers its normal rapidity of growth. This "reverted" form has a slight residual resistance, up to ten times that of the original culture.[13] The ability of these strains to withstand such high concentrations may not be entirely due to a specific penicillin resistance, but to their greatly reduced growth rate. This view gains some support from Demerec's[14] statistical demonstration that such resistance is not brought about by the action of the penicillin, but that the resistant forms arise as a chance mutation and are selected by the drug. Another type of penicillin-resistant staphylococcus is seen in the minute colonies which appear in the otherwise clear zones produced by penicillin in the ring test[15]: these grew slowly, and quickly reverted to a sensitive form on subculturing in normal broth. Other resistant strains are produced by the action of barium chloride on bacteria.[15] This salt is known to destroy or inhibit enzymes,[16] and the resistance of these variants is due to their lowered metabolic activity and slow growth.

It is stated that, unlike the strains made resistant *in vitro*, those obtained during treatment of animals and patients with penicillin are permanently resistant. This statement needs modification before it can be accepted. Schmidt and Sesler[17] claimed to have made a strain of staphylococcus permanently resistant in animals, but it had only four times the resistance of the original culture. Anderson and others[18] isolated resistant strains of staphylococcus from five patients after one week's treatment with penicillin, having shown that the original strains were sensitive. These resistant strains had sixty times the penicillin tolerance of the original strain, and the authors adduced some evidence that the resistance was permanent. The degree of resistance obtained by treatment in animals and patients is of the same order as the residual resistances of the " reverted " forms from the strains made resistant *in vitro*. It may be that much of the very high resistance obtained *in vitro* is due to non-specific effects on growth, and that the residual resistances obtained after reversion are a true measure of the specific permanent resistance of the strain. Such an effect on growth has been observed,[9] and results in the formation of " persisters," which, having temporarily lost the power to divide, were not killed by penicillin. These, on being placed into fresh broth, grew normally and were easily killed by the drug.

Very little is known of the mode of action of penicillin. It is inactivated by cysteine, but this appears to be by chemical action on the penicillin and not by interference with its mode of action. Nevertheless, it has been suggested that penicillin may act by interfering with the utilization of thiol groups by the growing cell.[19] It may interfere with an essential enzyme system in bacteria. It seems, however, to play a more positive part than a mere interference with growth.[9] It may itself form part of an enzyme system and usurp the functions of the normal bacterial enzyme. The fact that penicillin lyses only dividing cells is an important clue. The cell may become susceptible only at the time of division, or penicillin may become activated by bacterial substances produced at that time, or the cell may kill itself by its own products at the time it divides. It is difficult to absolve the cell from the charge of collaboration in its own death.

SULPHONAMIDE TREATMENT

One of the most useful of the M.R.C. War Memoranda is that entitled " The Medical Use of Sulphonamides " : since its first issue in 1943 over 50,000 copies have been sold. A second edition[20] has now appeared, to which considerable additions have been made. These are concerned not only with new sulphonamide compounds and with recent experience in the use of these drugs generally, but with the profound change in the chemotherapeutic situation which has been wrought by penicillin. Although the therapeutic use of penicillin is not within the scope of this monograph it was a subject which clearly could not be ignored, since the sulphonamides and penicillin are alternative treatments for many conditions, and the latter is often much the more effective. On the other hand, in the present state of availability of penicillin dogmatic assertion that it should be used, without mention of any alternative, would unfortunately not always be helpful. These difficulties have been met both by insertions in the text dealing with the individual treatment of many conditions and by a new section on the relation of the main subject to penicillin therapy; in this the spheres of the two forms of treatment are outlined, and in the wide domain where these overlap their respective merits are discussed. The strongest injunctions to use penicillin if possible are naturally given in connexion with severe staphylococcal infections of all kinds, most forms of purulent meningitis, and gas gangrene. Acknowledgment of its superiority to the sulphonamides is made in the treatment of wound infections, diseases and injuries of the eye, anthrax, bacterial endocarditis, gonorrhoea, and Vincent's infection, but instructions for the sulphonamide treatment of most of these conditions are nevertheless given. This is the only possible attitude to take at present, but it will be interesting to see how therapeutic policy will develop when penicillin becomes freely available. That penicillin will entirely supplant all other forms of treatment for gonorrhoea seems certain. Apart from the other conditions named it may well come to be regarded as the ideal treatment for most forms of pneumonia, and, as Helmholz and Sung[21] have pointed out, its concentration in the urine during systemic administration is such that even urinary infections due to some of the more resistant bacteria may be controllable. These and other possible spheres of penicillin treatment remain to be explored further.

The title of this memorandum is too modest: it deals not only with medical conditions in the narrower sense of the word, but also with surgical. The section on wound treatment is particularly thorough, although no attempt is made to pass judgment on the now disputed value of sulphonamide powder treatment as a preventive of wound infection. Several alternatives are offered, including proflavine–sulphathiazole powder—to which might have been added similar preparations of flavazole, a new compound the properties of which have recently been described by McIntosh and others[22]—a microcrystalline suspension of sulphathiazole, and marfanil. This last is one of the three principal new sulphonamides of which mention is made; it is suitable only for local application, peculiarly active against the organisms causing gas gangrene, and not inhibited by *p*-aminobenzoic acid or by pus. A mixture of marfanil (4-aminomethylbenzenesulphonamide) and sulphanilamide was extensively used by the Germans as a wound prophylactic. General instructions, condensed from other publications, including M.R.C. War Memorandum No. 2, are given for the treatment of gas gangrene, and the section on burns follows the lines developed in the Burns Unit, Royal Infirmary, Glasgow, and published in full elsewhere.[23] The two other sulphonamide drugs described for the first time are sulphamerazine and phthalylsulphathiazole, the latter being the latest addition to those drugs which remain largely unabsorbed and exert an action in the lower bowel. Among other additions is an interesting discussion on the value of group prophylaxis—i.e., the large-scale administration of small doses as a purely preventive measure in the presence of an epidemic. This measure has been used effectively against bacillary dysentery and streptococcal infections of the upper air passages; a short course will also eliminate meningococcus carriers, and a very prolonged course has been found to prevent relapses of rheumatic fever. The problem of sensitization to sulphonamides is also discussed, with emphasis on the peculiar liability to this of patients treated by applications to the skin. New proceedings are also described in the section on laboratory methods. A limited number of selected references is given in the text to recent papers or those dealing with matters on which the reader may wish to inform himself more fully. This memorandum remains a model of condensation and judicial appraisal: it contains as much information as the average book of many times its size, and possesses far more authority. It will doubtless remain the standard guide to its subject.

LEPROSY CONTROL IN INDIA

The largest number of leprosy cases in the British Dominions is met with in India on account of the immense population, though the rate per 1,000 is much higher in Africa in such Colonies as Nigeria. In 1941 the Central Advisory Board of Health of the Government of India issued a report on leprosy and its control in India. This dealt with the efforts of the two previous decades to apply recent advances in our knowledge of treatment and of incidence and epidemiology, furnished by the surveys of E. Muir and I. Santra, in controlling the disease by treating early cases on a large scale in numerous leprosy clinics, and in isolating the most infectious cases in leprosaria to keep down the number of new infections arising each year. The committee pointed out that dispensary out-patient treatment alone would not solve the problem and that little progress had recently been made in supplying the more expensive agricultural colonies for infective cases. The total number of leprosy cases in India is now estimated at 1,200,000, but fortunately only about one-tenth of them are highly infectious ones in urgent need of isolation. Only about 14,000 cases, including many uninfective nerve ones, are now isolated in India, but much remains to be done in this connexion before leprosy infections can be controlled and a start made in reducing the incidence of the disease. A paper by R. G. Cochrane[24] on leprosy control, with special reference to the Madras Presidency, is therefore timely. The first essential is the appointment to each Province of an experienced leprologist, with status and emoluments that will attract suitable men. Where this has not already been done surveys are needed to ascertain the usually limited areas in which the high incidence of the disease constitutes it an important problem. In each of these a large agricultural colony should be established for the isolation and efficient treatment of as many as possible of the infective patients, who alone should be admitted to them. Seven such areas have been defined in the Madras Presidency, so the cost will be high, and it is lack of funds that has hitherto prevented this essential step being taken. The Lady Willingdon Leprosy Sanatorium should be developed as a centre for the Madras campaign, with provision for postgraduate teaching and research. In rural areas the isolation of infective cases at night in special houses should be arranged for each infected village, because there are very few Indians who are well enough off to have the necessary accommodation to supply adequate home isolation. The care of uninfective crippled nerve cases, who constitute most of the beggar class, is a philanthropic rather than a public health matter; they should be looked after in separate institutions or in distinct sections of colonies. The Mission to Lepers provides for many of them with the help of Government maintenance grants. In the Madras Presidency orders have been issued to ensure that lepers requiring in-patient or out-patient treatment are to be cared for at all Government hospitals and dispensaries. Children's sanatoria are also required. Wherever well-equipped agricultural colonies are provided there is no difficulty in filling them with suitable voluntary admissions, but instances occur in which highly infectious patients refuse such accommodation. The Madras Government is therefore amending the law to provide for the compulsory isolation of these few refractory patients to prevent the whole scheme of control being stultified by their obduracy. Now that the vast expenditure by Great Britain and the U.S.A. in defending India and recovering Burma has converted India from a debtor to a creditor country, funds should be forthcoming in support of a determined effort to solve the leprosy problem by putting into effect the comprehensive measures above outlined.

BRONCHITIS AND PNEUMONIA IN LONDON INFANTS

The high death rate from bronchitis and pneumonia among infants under 2 years presents a serious problem in public health: in the decade preceding the war one-fifth of the deaths in this age group in London were assigned to these causes. The number and diversity of the micro-organisms responsible for these conditions add to the difficulties of finding a solution and put the problem in a different category from that of diphtheria or measles. G. Payling Wright and Helen Payling Wright[1] found in the London boroughs large correlations between the mortality and three indices of housing—the social class index, incidence below the poverty line, and number of children per family. It is difficult to establish the relative importance of these indices of social, economic, and environmental conditions because of the high correlation between them. Seasonal conditions seem to be the most important predisposing cause of fatality; the weekly death rate in winter is about seven times that of late summer. The correlation is largest between mortality and low temperature of two weeks earlier; the relation is such that mortality rises sharply when the mean temperature of the coldest day of the week falls below 40° F. It is suggested that the chilling of the infant's body, with a consequent lowering of the efficiency of the defence mechanism of the respiratory tract, permits the nasopharyngeal bacteria to extend to the bronchi and bronchioles and there set up foci of bronchopneumonia. The association between temperature and mortality may be the explanation of the less striking relation between mortality and substandard housing found in London and that found in Glasgow. The centre and more densely populated boroughs of

[1] *J. Hyg.*, Camb., 1945, **44**, 15.

London enjoy a higher minimum temperature than the outer boroughs, and the beneficial effects of a higher temperature may mask to some extent the relation between overcrowding and mortality. In their examination of other hypotheses of the winter rise the authors found that there was little evidence of seasonal variation in the virulence of pneumococci, streptococci, staphylococci, and haemolytic streptococci, and that it was improbable that the winter epidemics of bronchopneumonia could be adequately accounted for by a rise in the carrier rate. There is no support for the idea that susceptibility to the disease increases during the winter in consequence of the progressive depletion of protective nutrient substances in the body, since corresponding low temperatures in spring and autumn are associated with the same order of mortality.

Specific prophylactics can at present do little to prevent the disease; active immunization, even if possible, would not be practicable because the varieties of bacteria responsible are too numerous and too widely distributed in the community. Among the possible ways to reduce mortality from bronchopneumonia the authors suggest that educative measures directed towards the better protection of infants against chilling and exposure would have substantial success. Adequacy of clothing and the physiological reactions underlying the susceptibility of infants to cold are important questions in infant hygiene that require investigation. The chance of surviving an attack of bronchopneumonia largely depends on the promptness and efficacy of the treatment. If full advantage is to be taken of chemotherapy and oxygen therapy institutional treatment is necessary, and it is suggested that if certain hospitals had trained persons specializing in pneumonia, and if practitioners were encouraged to co-operate by sending patients promptly to such experienced medical teams, the mortality might be largely reduced. Of the various non-specific measures it is certain that progressive improvement in social conditions will be accompanied by a fall in the incidence of the disease.

WARTIME WORK OF PSYCHIATRIC CLINICS

The annual report of the Tavistock Clinic for 1943 is one of which those responsible may be justly proud. The admirable work of the clinic has been rewarded by increased support, especially from donations, so that the credit balance is now appreciably greater than it was. Working in their temporary premises at Westfield College in Hampstead the staff have dealt with increased numbers of both adults and children, more of the latter having been sent by local authorities and courts than ever before, showing that the official mind, perhaps rightly slow to adopt new methods and ideas, is beginning to recognize the value of skilled psychological treatment. Depression has been found to be the principal symptom, no doubt owing to the overwork and natural anxieties of wartime. Many people break down because they have been directed to unsuitable work. Again, it has been found that the children referred tend to be either retarded or specially gifted. Many who are sent because they fail at school are found to be of high intelligence, and their failure may well be due to the frequent change of school owing to war conditions. Its present success is undoubted, and with the removal to a permanent home at 2–4, Beaumont Street, London, W.1 (its own premises in Bloomsbury were destroyed by enemy action in 1941), the clinic will, we hope, continue to flourish as it deserves.

The Liverpool Psychiatric Clinic is to be congratulated on its coming of age and especially on the fact that this anniversary is reached with a satisfactory financial position. For all such enterprises, however, the future is uncertain, and continued and increased support is necessary. The report should persuade the public that money given for this cause is an excellent social investment. During the war the nature of the clinical work reflects the experiences of the population. States of anxiety associated with bombing, with casualties or possible casualties among relatives at home and over-seas, and with strange work and conditions of work, including direction away from home, are all reflected in the problems to be dealt with. Among children the " broken home " problem is now more acute than ever, and the increase in delinquency has brought a greater demand from courts and Home Office and educational authorities for the help which such a clinic as this can give. There is no lack of work, but staff is short at present. Financial aid and moral encouragement are the essentials for the continuance of this excellent service.

HEALTH OF THE SUDAN

The state of public health in the Sudan remains satisfactory in spite of the constant threat of the spread of epidemic disease from neighbouring countries. During 1943—the year which saw the end of the North African campaign—according to the report of the Sudan Medical Service, ten separate infections of smallpox were introduced—eight from Egypt and two from Saudi Arabia. The number of cases reported was 182, with 36 deaths. Over 750,000 vaccinations were carried out during the year, bringing up the number of vaccinations during the last seven years to 4,500,000. It appears, on the whole, that the Sudan is well immunized against smallpox and compares favourably with similar African countries in this respect. Four infections of typhus were introduced from Egypt, and the most energetic precautions were at once taken to prevent the disease, which had broken out in a frontier village, from obtaining a hold. The frontier was closed to land traffic except along the river on approved routes, and all persons entering the country by any of these routes were deloused and kept under surveillance. All civil and military passengers travelling third class on the Egyptian railways or on the Sudan Government steamers were deloused on embarkation and kept under surveillance. (Lice, one gathers, are too humble or too shy to travel first class.) Intensive delousing of the whole population—numbering about 35,000—of the Wadi Halfa area, where some cases of typhus had been reported, was carried out at 20-day intervals. In the result only nine cases occurred, with two deaths. Of the other epidemic diseases in the Sudan, cerebrospinal meningitis showed an increased number of cases, though a diminished death rate; diphtheria appears to be more prevalent in the Sudan as contact with the outside world grows, and relapsing fever, with 10,500 cases and 668 deaths, doubled its incidence as compared with 1942, and multiplied its death-roll by six as compared with 1941. The total number of lepers in the Sudan is given as 3,879, of whom 1,598 are under treatment, the remainder only under observation. In Northern Sudan, where the incidence of leprosy is low, lepers are dealt with by a system of home isolation; in Central Sudan small leper colonies have been established near hospitals and are supervised by the hospital staff; and in Southern Sudan, which is the only area where leprosy is of public-health importance, large settlements have proved satisfactory. Malaria, except in the north, is one of the principal scourges in the country. Nearly 15,000 cases were admitted to hospital in 1943. This report of the Sudan Medical Service includes short accounts of the work of the Stack Medical Research Laboratories, the Wellcome Chemical Laboratories, and the Kitchener School of Medicine. The Service, including these bodies, has an establishment of 846, of whom 585 are assigned to hospitals, 135 to the public health department, and 67 to research.

NUTRITIONAL DEFICIENCIES IN HONG KONG BEFORE THE JAPANESE INVASION

BY

LYDIA FEHILY, M.D.

Formerly L.M.O. (Maternity and Infant Welfare) and Visiting M.O., Chinese Dispensaries, Hong Kong

Much has been written about deficiencies in the diet of Chinese; indeed, the deficiencies described seem to be so widespread, severe, and multiple that one might well wonder how the Chinese nation was able to propagate and increase to the extent of 450 millions. However, in an article on the subject of nutritional problems in China (Heng Liu and Chu, 1943) the authors explain that, hitherto, all the research on diets in China has been undertaken in large industrial cities (i.e., Shanghai, Peiping, and Chungking), where the problem of inadequate diets was due to the low purchasing power of the average person. It is not surprising that undernourishment, or even plain starvation, was rampant (and still is rampant) sporadically in parts of China, the main causes being the lack of irrigation with resultant droughts and floods, persistent internal warfare, and, latterly, the Japanese invasion. Thus millions of displaced persons, in search of work or food, converged on large industrial cities, and the resulting saturation and unemployment, coupled with inadequate relief measures, gave rise to conditions of undernourishment or even plain starvation, associated at times with one or more specific deficiencies. Thus in one refugee camp in Shanghai the inmates were given only a bowl of gruel (of imported white rice), with a few vegetable leaves, twice a day. Naturally, severe cases of nutritional oedema and vitamin A, B, and C deficiencies began to appear in due course, but such food cannot be regarded as the customary diet of the Chinese.

High Mortality in Hong Kong

The conditions in Hong Kong were entirely different from those of cities on the Chinese continent. Until 1941 Hong Kong was spared from war and hostilities, its population enjoyed a relative economic prosperity, there were adequate relief measures, and, in addition, the climate did not show extreme variations of heat or cold, there were no droughts or floods, the soil produced three crops a year, while the neighbouring waters were rich in fish. Nevertheless, the total death rate in Hong Kong was higher than that reported in cities in China, and the infantile mortality rate (345 per 1,000 live births in 1939) was one of the highest in the world. Mainly on account of this high infantile mortality, the total death rate in Hong Kong (27.6 in 1939) was surpassing the birth rate (26.7 in 1939); indeed, but for immigration Hong Kong would have faced depopulation.

High Mortality and Immigration

The commonly accepted explanation of the high mortality and morbidity in Hong Kong was that, owing to unrestricted immigration, "the lame, the halt, and the blind" from the whole of South China might congregate there. However, this explanation, as shown below, is not convincing.

Owing to overpopulation in the interior of China, the Chinese, even without *force majeure*, were obliged to emigrate, with preference for over-seas or Shanghai and Hong Kong. When relieving a surgeon on an emigrant ship I was able to observe that, while the exiles returning were human derelicts (mostly victims of beriberi or opium-smoking), the emigrants, on the outgoing voyage, were in good physical health. Therefore I concluded that the fittest and ablest went abroad in order to procure the necessary funds to support their family at home. However, later on (in 1942), while travelling through Kwanchewan and the provinces of Kwangtung, Kwangsi, and Yunnan (all in South China), I noticed that the physical health of the population in general was excellent, and in six weeks' travel through those provinces I was unable to detect any obvious signs of deficiency diseases or gross undernourishment. On the contrary, the stamina of the natives there was astounding and could not easily have been surpassed by any other nation: coolies clad only in cotton singlets and shorts were carrying, on daylong marches in cold November rain, loads up to 200 lb. each, while the greatest part of the population, under similar conditions, were working in paddy fields, knee-deep in water. Obviously such feats could be undertaken only in perfect health and on a well-balanced and adequate diet.

Moreover, Chinese, when sick, do not leave their native land, but, on the contrary, ailing and aged Chinese seek to return to their ancestral homes so that their bones may be laid there and their spirits be gathered unto their forefathers.

To prevent dissemination of infectious diseases, persons arriving in Hong Kong were medically examined and were required to produce valid vaccination and inoculation certificates, unless the ports of origin or of transit were free from quarantinable disease; but in spite of these precautions, cases of infectious disease were imported, especially from neighbouring ports, such as Canton and Macao. However, the infectious disease rate, although some diseases were endemic in Hong Kong, constituted only a minor part of the total death rate.

Admittedly, considerable numbers of destitute and unemployable persons arrived from the hinterland and from the neighbouring ports of Canton, Macao, and Swatow, but they seem to have been easily assimilated, as the number of beggars and destitutes was proportionally much lower in Hong Kong than in Chinese cities. Consequently the unrestricted entry of Chinese into Hong Kong would not seem to be an adequate explanation of the high morbidity and mortality figures there, especially as entry is unrestricted into all Chinese cities, which, moreover, have more primitive sanitation and water supplies, less extensive medical services, etc.; but, in spite of that, as stated above, the recorded death rates in these cities are lower than those in Hong Kong. Thus in Peiping, according to statistics compiled by the Peking Union Medical College (a Rockefeller institution), the death rate is approximately only half of that in Hong Kong.

High Mortality and B_1 Avitaminosis

It may therefore be more justifiable to ascribe the main cause of high morbidity and mortality in Hong Kong to the choice and condition of the staple food. While the rural population in North China consumed such staples as gaolian (brush-wheat), millet, maize (all home-grown, whole-grain cereals), or soya-bean flour or lightly milled wheat flour, and that in South China used as staples home-grown lightly milled (mostly hand-pounded) rice, and urban Chinese were supplied either wholly or partly with the above-mentioned cereals, Chinese in Hong Kong consumed only imported machine-milled rice of low extraction. As a result of such a staple, B_1 avitaminosis was widespread and manifested itself mainly in lack of resistance, especially against respiratory diseases (which topped the list as causes of death), or beriberi (which, since 1940, was second on the list). In lactating women, however, B_1 deficiency (mainly latent) resulted in high infantile mortality (Fehily, 1940, 1944). When the symptoms of beriberi appeared Chinese in Hong Kong frequently attributed this condition to "bad" water (i.e., chlorinated) and, when possible, tried to return to their native villages to be cured, but often only to be buried there. After the occupation of Canton and the Kwangtung coast by the Japanese their return was cut off, and this resulted in a sudden increase in the numbers of cases of and deaths from beriberi. In addition, since 1939, in view of the danger of hostilities in Hong Kong, large stocks of imported and, unfortunately, milled rice were stored in the colony. This milled rice, which had been deprived of most of its vitamins as well as protective husks, was subject to more rapid deterioration, and the remnants of vitamin B complex were the first to disappear. In 1940 this long-stored rice began to be distributed to the population and, as was to be expected, this caused a further increase in B_1 avitaminosis and the appearance of pellagra and ariboflavinosis. Influx of refugees and consequent deterioration of living standards were blamed for this occurrence, and to improve conditions price control was instituted and all those who were destitute or unemployable were segregated, often forcibly, in refugee camps established by Government. However, the incidence of B_1 avitaminosis steadily increased (in direct proportion to the deterioration of rice), and just before the Japanese aggression the hospitals in Hong Kong were unable to cope with all the cases of B avitaminosis (mainly B_1) and its complications.

After the occupation of the colony by Japanese this long-stored rice was supplied to the prisoners of war and civilian internees, and within three months vitamin B deficiency, in the form of beriberi, began to appear among them. Fortunately, the prisoners of war, followed by civilian internees, managed to grow yeast, and thus saved themselves from this disease, to which most of them otherwise would have succumbed in due course.

Vitamin C Deficiency only Secondary

One of the early symptoms of B_1 avitaminosis is gaseous distension of the abdomen. In search of an explanation for this symptom, Chinese came to the erroneous conclusion that fruit and vegetables, being gas-producing, were the cause, and it became customary for them to abstain from fruit and vegetables on the onset of this and other symptoms. Hence one occasionally encountered vitamin C deficiency but, in my experience, it was always secondary to a deficiency of vitamin B, mainly B_1. (Inability to absorb vitamin C, due to gastric disturbances encountered in B avitaminosis, might be an additional factor.)

Occasional Vitamin A Deficiency in Unwanted Female Infants

Vitamin A deficiency was sometimes encountered in infants fed on rice paste or masticated cooked rice, but it also was secondary to the deficiency of vitamin B, and was often associated with infantile scurvy. In all such cases the infants were unwanted baby girls, who had either been "adopted" by unscrupulous women or left in the care of old grandmothers or elder children, who did not consider it worth while to apply for free condensed milk (which, in any case, is preferable to masticated rice). So far as I know, vitamin A deficiency in adults has not been observed, probably owing to the extensive consumption of fish, which often, in the form of sprats, etc., were taken whole.

Absence of Other Deficiency Diseases or Starvation

For the same reason there were no manifest signs of protein deficiency and no clinical or radiological symptoms of rickets, although the absence of the latter might be also attributed to the abundance of ultra-violet rays. (One case of rickets among approximately 5,000 infants and children observed by me might have been due to faulty assimilation.) The requirements of fat were supplied by cooking fat (of vegetable origin) and by fish and meat (mostly pork). It would seem that the fat requirement and tolerance for fat in the case of Chinese in Hong Kong are below those of Europeans. Certainly, full-cream dried milk, reconstituted in accordance with the recognized formulae, is not tolerated by Chinese infants. Although water in Hong Kong was rather poor in calcium, deficiency of this salt was not observed by me, possibly because of its excellent assimilation; dentition in infants was normal, and in general the teeth of Chinese were good.

Although undernourishment was not uncommon, real starvation should not have occurred. Free food kitchens, maintained by missionary and benevolent institutions as well as by Government, were available for the poor, and as a general rule the cost of food was reasonable. There was an abundance of cockles, clams, and mussels on many Hong Kong beaches, and at low tide one saw hundreds of women and children quickly filling up their baskets with them and selling the surplus for almost nothing.

Variety and Wholesomeness of Supplementary Food

In South China, as a matter of choice and not from necessity, 70 to 80% of the diet of Chinese of the lower and lower middle classes consists of rice. They explain that only rice satisfies their hunger, and even well-to-do Westernized Chinese demand a bowl of plain cooked rice at the end of a sumptuous banquet, otherwise "they still feel hungry." A Chinese manual worker can eat up to 2½ lb. of rice a day, and the supplementary foods —"sung"—were taken rather as appetizers. The number of "sung" dishes varies with the occasion and the number of persons partaking of the meal, and they include such nutritious foods as bamboo shoots, sprouting beans, and soya-bean curds. It is usual for a single person to have two "sung" dishes: one of lightly fried vegetables and the other of fish (often sprats) or sometimes meat (mostly pork). The ingenuity displayed by Chinese women in procuring an additional dish of "sung" is remarkable: those living on the hills removed from the sea collect snails, and women of the floating population collect roots of the grass which grows on sandy beaches. In addition they prepare the food (except rice) in the most vitamin- and mineral-saving way: thus green vegetables are only lightly fried with oil, and are eaten while still crisp. Indeed, I do not remember any dish whose cooking water was thrown away (unlike some European methods), and the Chinese, as a rule, are not guilty of overcooking. Unfortunately rice, before cooking, was washed in a few waters and occasionally it was soaked, but Chinese explain that otherwise rice in Hong Kong, being machine-milled and not fresh, tastes of polishing powder and smells of mould. It would seem that the supplementary food was not only well cooked but was varied, tasty, and wholesome, and contained the required amount of all food factors except vitamin B. However, for the complete oxidation of such great quantities of refined carbohydrates (in the form of highly milled rice) assimilation of the amount of vitamin-B_1-containing supplementary food would be beyond the physical capacity of Chinese. If any reduction in the intake of rice was suggested it was not uncommon for Chinese to retort: "But for centuries my ancestors and the people in our village lived mainly on rice, and they were rarely sick, and some lived to be over a hundred years old." This attitude is perfectly comprehensible, taking into consideration the fact that most people in the British Isles still cannot be made to realize the beneficial qualities of the "national loaf."

B Avitaminosis and the Economic Position

It has been stated by Wilkinson (1944) and others that B avitaminosis is associated only with poverty, and consequently one might believe that improved economic conditions would lead to eradication or at least mitigation of this disease. My own observations, however, have led me to believe that this is not the case, as improved economic conditions often resulted in Chinese of the labouring classes consuming larger quantities of the "best" rice—i.e., of the lowest extraction possible. Indeed, the few cases of acute cardiac beriberi seen by me occurred in prosperous people of the lower middle class. Apparently similar results were observed on the island of Nauru (Bray, 1929), in South Africa (Kark, 1943), and the Netherlands East Indies (Wilcocks, 1944). On Nauru the natives, on receiving royalties for their phosphate mines, ceased to work, and replaced their native agricultural produce with imported foodstuffs, such as white flour, refined sugar, and tinned meat. In due course infantile mortality (caused by latent maternal B_1 avitaminosis) rocketed to 40%. In South Africa the natives abandoned agriculture for more profitable work in war industries and changed to a diet consisting mainly of imported white flour and tinned meat, with the result that pellagra has considerably increased. In the Netherlands East Indies, at the time of the rubber boom, beriberi was widespread, but before the present war this disease was encountered only in urban areas among well-to-do classes, who consumed large quantities of refined carbohydrates (mostly imported rice). Indeed, Western civilization would seem to have been of doubtful benefit to Far Eastern peoples, so far as their health was concerned, as the introduction of this civilization was usually marked by the importation of refined carbohydrates—e.g., rice, white flour, sugar, and alcohol—or the machinery for refining their native products.

Prevention of B Avitaminosis. — Although suggested measures for the prevention of B avitaminosis in Hong Kong have been discussed elsewhere (Fehily, 1941), it might not be superfluous to stress once again the need for prohibiting the importation of highly milled rice into the colony. It was suggested that rice which retains approximately 25% of the external layers (i.e., pericarp and aleuron with adhering embryo) would be B-avitaminosis-preventing rice, and at the same time it would be the most suitable rice as regards taste, appearance, and time required for cooking.

Summary

Widespread vitamin B (mainly B_1) deficiencies have been observed in Hong Kong—due to the consumption of imported highly milled and, latterly, long-stored rice.

The vitamin C deficiency occasionally encountered in Hong Kong was commonly associated with primary vitamin B (mainly B_1) deficiencies.

Practically no other deficiency diseases were observed.

It is suggested that the high mortality in Hong Kong (the highest reported on the Chinese continent) may be due to the fact that in Hong Kong, unlike Chinese cities, practically all the rice consumed was imported machine-milled, and of very low extraction.

The effects on the health of Far Eastern peoples of importing refined carbohydrates are pointed out.

The necessity for prohibiting the importation of highly milled rice into Hong Kong is stressed.

CHRONIC RHEUMATISM IN SCOTLAND

MEDICAL ADVISORY COMMITTEE'S REPORT

The Department of Health for Scotland issued last week a report on chronic rheumatic disease by the Scottish Medical Advisory Committee. The preparation of this document was entrusted to a subcommittee consisting of Sir John Fraser (chairman), Sir Alexander S. M. Macgregor, Prof. Adam Patrick, Dr. D. Dale Logan, and Dr. A. F. Wilkie Millar, with Dr. J. M. Johnston as medical secretary. The report is published at 6d. by H.M. Stationery Office.

In the course of its investigations the subcommittee obtained evidence from representative clinical and technical experts of wide experience in the treatment of chronic rheumatism; its members visited the principal rheumatism clinics in Scotland and had an opportunity to observe the distressing terminal stages of rheumatism as seen in patients within a hospital reserved for the care of the infirm and incurable. In its opinion many of the severe deformities were the result of ineffective treatment or lack of treatment in the early stages of the disease. Its report forecasts a long-term programme of carefully co-ordinated research "from which speedy or spectacular results must not be expected." Its chief recommendation—the setting up of small investigational units at the teaching hospitals, linked with beds at country hospitals for long-term treatment—may be acted upon in the near future, even if on a limited scale. Early in its discussions the subcommittee decided that acute rheumatism, a subject of the first magnitude, lay outside its terms of reference.

In recommending to the Secretary of State that the report should be published, the Medical Advisory Committee stresses its anxiety that publication should not give rise to expectations which cannot quickly be fulfilled. "Any publicity which it may receive should not prejudice the position by raising false hopes in respect of results or in hindering the scientific control of the experiments by inappropriate selection of cases." Summing up present-day knowledge regarding the causation and results of treatment of the chronic rheumatic diseases, it emphasizes that too little is known on the subject. The medical profession is conscious of a serious deficiency in reliable knowledge and a lack of facilities whereby patients can be properly investigated and adequately treated. Substantial contributions to knowledge have been made, however, in the last twenty years, and it is thought opportune to bring the problem of rheumatism into proper focus in relation to imminent developments within the National Health Service.

A Social and Economic Problem

In general, mild attacks of "rheumatism" are so common that many people look upon it as "almost a benign infirmity." Formidable figures are quoted, however, to show the more serious aspects of rheumatism as a social and economic problem. Statistics for the industrially insured population of Scotland show that in the year 1937-8 one in every 37 males was incapacitated by rheumatism, and one in every 50 females. In each year it is estimated that (for men) one in every 21 miners, one in every 29 general labourers, and one in every 37 transport workers have to cease work for some period or other on account of rheumatic affections. For women, corresponding figures show one in every 37 domestic workers (including charwomen) and a similar proportion for agricultural and fishing workers. The committee notes as significant that at one busy rheumatism clinic the number of housewives attending for treatment was fully twice that of men.

A wider and more accurate form of statistical information is needed to survey properly the magnitude of the question. From early adult life onwards, irrespective of age, sex, and occupation, no one can be considered immune. "If to the total invalidism were added the loss in wages, and the expenditure in sickness benefit and treatment, the cost to the nation would in itself prove large enough for rheumatism to rank as a major problem." Referring to earlier investigations into the problem, the report quotes from a 1937 survey of Aberdeenshire, where it was discovered that nearly 10% of all professional work carried out by doctors was concerned with the diagnosis and treatment of rheumatic and allied conditions. Similar figures were forthcoming from the experience of one Army convalescent depot during the war.

There are strong indications, the report states, that the incidence of rheumatism is influenced by occupational environment. Over 80% of the cases are located in the industrial and large burghal areas; the Highlands and Islands show an all-round low average rate, though the period of incapacity is prolonged, due, it has been suggested, to the lack of facilities for adequate modern treatment, and a tendency for many patients to remain at work until severely crippled. Drawing attention to the inadequacy of existing facilities in Scotland for the diagnosis and treatment of rheumatism, the report commends the work of the three orthopaedic and rheumatism clinics at Glasgow, Dundee, and Edinburgh. Problems of accommodation are illustrated by reference to the buildings occupied by these clinics—a terrace house in Edinburgh with every available corner used for some form of therapy; the high standard of work maintained in Glasgow in a church building, where even the organ loft and underground basement are utilized; a factory building in Dundee, converted into a highly efficient clinic, but there are too many stairs for the comfort of patients and staff.

Reference is made to the "large number of remedies and nostrums advertised to the public as specifics for all kinds of rheumatic complaints . . . many of them sold under obscure trade-mark names at a price far above the market value of the ingredients. . . . The anxious or depressed person is especially susceptible to advertisements for antirheumatic remedies." The report also draws attention to the readiness with which the continued use in rheumatism of even such simple drugs as aspirin or phenacetin may lead to a form of addiction to remedies containing them, and reminds medical practitioners to be on their guard against the danger which may follow the continued administration of morphine or related alkaloids for the relief of pain in chronic rheumatic conditions.

Some Recommendations

In addition to the 20-40-bed units recommended to be associated with the four Scottish universities, long-term accommodation on a regional basis should be reserved for rheumatic patients for whom there is a reasonable prospect of alleviation or cure. Medical supervision and research must have continuity. No special building programme is necessary, hutted accommodation of the type employed under the E.M.S. scheme being sufficient for initial needs.

Hospital facilities should be available for the investigation of every case of articular rheumatism to establish the diagnosis and determine the appropriate treatment. There is need for an authoritative review of the whole field of therapy to assess the value of the various methods and to initiate research for new and more effective remedies. These investigations should take into account the question of diet in relation to rheumatism and the therapeutic value of bacteriological and immunological products. Discussing possible improvements in methods of treatment one recommendation is that in the training of physiotherapists more emphasis should be laid upon active exercise and less upon elaborate apparatus. Every medical student as part of his course in therapeutics should be given an outline of the principles of physical therapy supplemented by practical demonstration within the department of physical medicine. In postgraduate courses for general practitioners more instruction should be given in the methods of physical therapy and the indications for their use in the field of general therapeutics, with due reference to their application in the treatment of rheumatic diseases.

There is a definite place for peripheral clinics, provided that a start is made on modest lines. These clinics should be associated with the orthopaedic service and linked with the hospitals. An essential part of the policy should be the discouragement of haphazard local effort. In accordance with the principle that the subject of rheumatism ought not to be divorced from general medicine by the creation of a narrow specialty the committee is opposed to the establishment of clinics designed solely for the treatment of rheumatism. Recommendations are made on the staffing of peripheral clinics and the follow-up and care of cases after discharge.

The provision of expert information and assistance to medical practitioners will do much to overcome the prevailing feeling of helplessness in regard to the treatment of rheumatism. On the other hand, it is inadvisable to make rheumatism the subject of a propaganda campaign addressed to the general public when so many people suffer from the disease and the existing facilities for treatment are so inadequate. "The best publicity in our view will be a good service with good results."

FACULTY OF OPHTHALMOLOGISTS

The following statement has been received for publication:

Meetings between representatives of the Council of the Faculty, the Council of the Association of British Ophthalmologists, and the Council of the Ophthalmic Group Committee (British Medical Association) have been held. Agreement has been reached regarding the constitution of the Faculty, including new criteria for membership and associateship, and revised arrangements for the election of Council. For the original statement on the formation of the Faculty reference should be made to the *British Journal of Ophthalmology* of February, 1945, to the *British Medical Journal* of Feb. 3, 1945, or to the *Lancet* of Feb. 3, 1945. As a result of this agreement the Council of the Association of British Ophthalmologists were enabled to urge all their members to join the Faculty, and to approve the dissolution of the Association in order that it may be merged into the Faculty. A postal ballot of members of the Association has revealed the necessary majority in favour of dissolution. A new Council of the Faculty is to be elected after due time has been allowed for all, including serving ophthalmologists, to join the Faculty; in the meantime any applications for membership or associateship which present any doubt are to be scrutinized by a joint committee representing the Council of the Association of British Ophthalmologists and the present Council of the Faculty.

The following are the new criteria:

Membership.—(1) Any ophthalmologist of the status of ophthalmic surgeon or assistant ophthalmic surgeon who holds an appointment on the staff of a voluntary or municipal hospital with a recognized eye department. (2) Any ophthalmologist, no longer on the active staff of a hospital, who has held such an appointment. (3) Other ophthalmologists of consultant rank approved by the Council, including those in the Services or holding Government appointments, and those of the British Commonwealth and Empire over-seas.

Associateship.—(1) Full-time ophthalmologists of two years' standing. (2) Part-time ophthalmologists of two years' standing, holding a hospital appointment or possessing a special diploma. (3) Practitioners who on June 1, 1945, were on the N.O.T.B. list.

Council.—The Council shall be increased in number to 25; the number of regions to be increased to 6, to correspond with the regions defined by the British Medical Association. The Council shall be constituted as follows: (1) One member elected from each region by a local regional vote of members. (2) Twelve members elected by a national vote of members. (3) One associate elected from each region by a local regional vote of full-time associates, representing the full-time associates. (4) One part-time associate elected by a national vote of part-time associates, representing part-time associates. (5) Any member of Council shall be free to stand for election indefinitely, if properly proposed and seconded.

The outline of the constitution, functions, and management of the Faculty included in the statement published in the medical press and as amended above will in general terms remain valid. As soon as the new Council is elected, the constitution and by-laws will be legally drawn up.

Forms of application for membership or associateship of the Faculty may be obtained from the honorary secretary, 45, Lincoln's Inn Fields, London, W.C.2.

STEWART DUKE-ELDER, *President*,
FRANK W. LAW, *Secretary*,
Faculty of Ophthalmologists.
J. N. TENNANT, *President*,
H. R. BICKERTON, *Secretary*,
Association of British Ophthalmologists.

BRISTOL AND DISTRICT HOSPITALS

The Bristol and District Divisional Hospitals Council has published its fourth annual report. The Council consists of representatives of the voluntary, municipal, and county hospital authorities and medical organizations in the city of Bristol and the counties of Gloucester and Somerset. It includes a representative (Dr. H. M. Golding) of the Bristol Division of the B.M.A., and a representative (Dr. C. Dix) of the Bristol Panel and Local Medical Committee. Recently the Council has decided to grant a representation of eight members to the three public contributory schemes operating in Bristol and Kingswood and to two private works' hospital funds. It is stated in the report that the area covered by the Council, expanded to include Wiltshire and the cities of Bath and Gloucester, has been largely accepted as the suitable one for the planning of the West of England Hospital Services. It is proposed to cover this three-counties area with four local joint consultative committees, and then to set up a co-ordinating committee for the area of which Bristol is the natural medical teaching centre.

The standing committee of the Council has devoted much time to the important subject of rehabilitation, and convened a meeting of directors of leading Bristol industries to whom it suggested that something more must be attempted forthwith to facilitate the recommendations of the Tomlinson report than so far it has been possible to achieve. The Bristol Council for the Disabled has already laid down a basis for a service, and the meeting of manufacturers decided to call together a committee formed on the initiative of the Bristol Chamber of Commerce and Shipping to examine the financial questions involved in carrying out the plans which the Bristol Council for the Disabled has suggested.

The Council, besides a grant for its administrative expenses, received a fourth grant, amounting to £1,000, from the Nuffield Provincial Hospitals Trust. Both the Council and the Trust doubted, however, if the distribution of the grants in small sums to constituents was a desirable policy to be continued, and accordingly it was recommended to the Trust, and agreed, that the grant be made to the University of Bristol—half for research into the treatment and prophylaxis of acute rheumatism in childhood, and half for research on Ménière's disease.

Many other matters of interest are referred to in the report, including a meeting with the city engineer concerning the proposed new lay-out of roads in the replanning of Bristol, in so far as these might affect hospitals in the central area.

THE WELLCOME MEDICAL MUSEUMS

The Wellcome Foundation has appointed Dr. E. Ashworth Underwood as Director of the Wellcome Historical Medical Museum and the Wellcome Historical Medical Library; he will take up his new duties as soon as he can be released from his present post of medical officer of health and chief school medical officer of the County Borough of West Ham. During the past five years Dr. Underwood has been honorary secretary of the History of Medicine Section of the Royal Society of Medicine. He has contributed to the *Proceedings* of that Society, and to other journals, studies on the history of certain infectious diseases, on the medical importance of Lavoisier and the French chemists, on the earlier anatomists, and on other subjects. He has for some time been collaborating with Prof. Charles Singer in work on Vesalius. Wing Commander C. J. Hackett has been appointed Director of the Wellcome Museum of Medical Science in succession to Dr. S. H. Daukes, who has been responsible for the development of this museum during the last 26 years. Dr. Hackett, who was a Research Fellow in Tropical Medicine of the Medical Research Council and has done work on yaws and other tropical diseases, will take up his new post as soon as he has been released from the Royal Air Force.

OPENING OF MEDICAL SCHOOLS

LONDON SCHOOL OF MEDICINE FOR WOMEN

Lord Moran's Philosophy

The inaugural address at the London (Royal Free Hospital) School of Medicine for Women was delivered on Sept. 28 by Lord Moran, P.R.C.P. The Dean, Dr. Elizabeth Bolton, who presided, paid a tribute to Lady Barrett, who was president of the School at the time of her recent death. She also mentioned that the students this session in the first medical course numbered 70, and in the second 30.

Lord **Moran** began by asking why it was that so few old students remembered anything that was said in inaugural addresses by distinguished persons. Partly it was because the student had not much use for improving discourses, and partly because the student soon perceived that the orator was not saying what he thought, but what he was supposed to say on an occasion. Lord Moran himself, therefore, adopted an unconventional line, forsaking the usual reference to Florence Nightingale and the emancipation of women, of which that School had heard much, and confined himself to some practical "Don'ts." He advised the students, in the first place, not to be too gregarious. In this thickly populated land we lived too much on the top of one another. Our very thoughts were borrowed thoughts, and even teachers did not always encourage their students to think for themselves. Much was heard of the shortcomings of examinees, and little about the frailty of the examiner. So often examiners tried to find out what a student did not know, so that the student tried to acquire a smattering of everything, whereas if the examiner tried to find out what he did know the student would be content to miss some things in order to know others really well. Examination was a form of criticism, and as in the criticism of a book or play the examiner or critic should not try to be clever in an obstructive way but rather to put his finger on what was best.

In spite of all discouragement, however, the student, when qualified, would have to think for himself, the more so because at the present time the Government was putting a fundamental question to the nation: Was the stimulus of competitive life, with its prizes for the successful, the right or only spur to bring out the best in men and women, or would they do equally well in a national service? "If you have been taught to think for yourself, then worry out the answer impartially and let us have it." What were the spurs to endeavour? It was foolish to underrate the money motive, but it was easy to exaggerate it. In science some of the most critical minds were eager to work in a service, often poorly paid but rich in happiness, because it enabled them to do the work they wanted to do and under the best possible conditions.

Another of Lord Moran's "Don'ts" was "Don't become a drudge. Don't dull your wits by too much work." After all, they had only one life to live, and might as well be happy in it. What was it that made a man happy? First and last and all the time, it was temperament. A cowman whom he knew worked early and late, but was always singing snatches of song, and although he was always in the same little spot he "seemed to get more kick out of life than I who have wandered over half the Western world these last five years." Another piece of advice was not to make a god of security. "Don't think always of safety first. I do not want you to tilt at windmills as I have done, because you get a good deal bruised, but take some hazard." Another warning was against the dangers of publicity to the doctor. The late Wilfred Trotter once said to him, "When the poison of publicity once gets into a doctor's veins there is no cure, medical or surgical." The general practitioner should choose his consultant because he had been impressed by his teaching or by what he had written or done, and not because some uninformed public clamour had brought him to the front.

Finally he paid a tribute to the dean of the school, Dr. Bolton, who had served in that office for 14 years, and was shortly retiring. A dean had the task of selecting the entry. "Give me the choice of the school entry and anybody else can have all the rest." A great school was a school with exceptional students. After all, the medical profession was what its individual members made it, and those members were chosen by the deans, so that the deans had the health of the profession in their hands. That was why he sometimes hoped that deans would have a prestige in the future which they did not enjoy at present, would hold a prized appointment, what was considered a great office in the State, so that they would talk of a great dean as they talked of a great headmaster or headmistress. Deans had an immense opportunity. If they could speak to young people twenty or thirty years their junior in such a way that the difference in years was not noticed on either side the effect on the school would be beyond all estimation.

"Perhaps young people to-day who feel that somehow all the greatness of life has gone and that beauty has vanished from the earth, and have a sense of grievance that their lives should have been matched with such ill times, may have a word of reassurance. A few days ago I was in one of the loveliest of Italian bays, and 36 hours later I was at my cottage in England. I put my bags in the hall and went out to the meadow where the cows were whisking the flies away with their tails, and the rooks were rising with a great cawing, a black cloud against the blue sky, and the mowing machine was heard in the distance, and it came upon me all at once that there is no country in the world which is a patch on England, and with their tolerance and good nature and fair minds no people half so civilized as our own countrymen."

A vote of thanks to Lord Moran was proposed by Mr. L. E. C. Norbury and seconded by Dr. Hazel Chodak Gregory.

MIDDLESEX HOSPITAL SCHOOL DINNER

Middlesex Hospital men past and present to the number of 200 dined together at the Savoy Hotel on Sept. 28. It was recalled that the previous reunion was held on the fateful night in September, 1938, when Mr. Chamberlain flew back from Munich. The speeches were largely a recounting of hospital and school happenings during seven eventful years. The Hon. J. J. **Astor**, who presided, spoke in thankfulness of the survival of the hospital amid the hazards of war. The total casualties were one member of the Friends Ambulance Unit killed, one seriously wounded, a number of patients injured, chiefly by flying glass, and a certain amount of structural damage. The plans for the future of Middlesex which had been worked out before the war had not been altered except in minor details. The celebration of the bicentenary of the hospital, due this year, had been postponed until 1946.

According to tradition, the responses to the toast of "The School" were made by the Dean, Dr. H. E. A. **Boldero**, and the senior Broderip scholar, Mr. A. S. **Burgen**. Dr. Boldero described wartime vicissitudes, the early migration of the preclinical school to Bristol and the dispersion of the clinical students among the sector hospitals. He said that there were now eleven vacancies on the medical and surgical staff, some of which had arisen owing to normal retirements, but others, unhappily, through the cutting short of promising careers. These were vacancies that must be filled, but wisely and not hurriedly. Sir **Alfred Webb-Johnson**, P.R.C.S., in proposing the health of the Chairman, mentioned that twenty-five years ago Col. Astor, by a most generous gift, which remained anonymous for a very long period, endowed the chair of physiology. Since then he had been a benefactor to the hospital on many occasions. In him, as chairman of the hospital, the staff felt that they had a true friend, one who understood the spirit of the voluntary hospital whereby the staff were part of it, and not in the mere relation of employed to employer. He hoped that in the future plans for Middlesex there would be a centre where the members of the staff could carry on their private consultations with the background of the hospital behind them. It was not very important that a surgeon should have Chippendale chairs in his consulting-room, but he could render better service if he had at his immediate command the best and most modern aids in diagnosis and treatment.

Among the guests at the dinner were the President of the Royal College of Physicians, the Directors-General of the Medical Services of the Royal Navy, the Army, and the Royal Air Force, Sir Lionel Whitby, Regius Professor of Physic at Cambridge, Sir Allen Daley, chief medical officer of the L.C.C., and the Mayor of St. Marylebone.

VASOCONSTRICTION IN MINUTES . . .
BACTERIOSTASIS FOR HOURS

‘SULFEX’

FOR INTRANASAL USE

(A *suspension* of microcrystalline (‘Mickraform’) sulphathiazole, 5%, in an isotonic solution of ‘Paredrinex,’ 1%)

The intranasal instillation of ‘Sulfex’ has proved strikingly effective in the treatment of nasal and sinus infections. The suspension has the following advantages :—

(1) **Prolonged Bacteriostasis.** The ‘Mickraform’ crystals of sulphathiazole are not quickly washed away, but form an even frosting over the nasal mucosa, thus providing bacteriostasis where most needed.

(2) **Non-Stimulating Vasoconstriction.** While ‘Paredrinex’ exerts a rapid and complete shrinking action, it does not produce nervous side-effects.

(3) **Therapeutically Ideal pH (5.5 to 6.5).** ‘Sulfex’ does not cause stinging or irritation. Its slightly acid pH range is identical with that of normal nasal secretions.

Samples and further details on *signed* request of physicians

METHYL-THIOURACIL B.D.H.

For the Treatment of Thyrotoxicosis

The value of thiouracil in the treatment of thyrotoxicosis has been established. Provided it is given under close supervision the toxic symptoms which occur in a few cases can be controlled.

A derivative of thiouracil, 4-methyl-2-thiouracil, also has been used; it is at least as effective as thiouracil and possibly less toxic.

Unfortunately Thiouracil B.D.H. is in short supply; on the other hand, Methyl-thiouracil B.D.H. is now freely available for general clinical use. It is issued in tablets of 0.05 grm., 0.1 grm. and 0.2 grm. in bottles of 100, at 2s. 6d., 3s. 9d. and 6s. 7d. respectively. Further particulars are available on request.

Correspondence

The Urgent Needs of Civil Medicine

Sir,—In your current issue you publish a letter from Professors Huggett and Killick on the educational conditions of our universities and medical schools.

The letter is a temperate one, and will command a very considerable degree of assent. Incidentally it would appear to make complaint of action by the Services Committee which is not justified, but the sentence on which I wish specially to comment is that in which it says, "The needs of the universities and medical schools must, therefore, be regarded as having the same degree of urgency as the needs of other branches of civil medicine."

From my experience of the demands made upon the Services Committee the time for this is premature. The needs of civil medicine which are most urgent are those of the general practitioner. Hundreds of aged general practitioners are continuing to work long after they both wish and ought to retire. Many have broken down, more are breaking down, not a few have died, a few have committed suicide. Their patients are suffering from lack of attention, and this quite unavoidably. Only just less urgent are the needs of hospitals, and these may be regarded as including the needs for consultant and specialist services. Hospitals are short of staffs as they have never been, this also when the demands upon them are greater than they ever were. Public health services are stripped to the bone, and the necessity for their reinforcement is very great.

The needs of these services are present and everyday, those of universities and teaching schools are more for the future. It is my considered opinion that until this winter, at least, is over, and probably well into next year, the urgency of the needs of teaching must rank behind that of these everyday services. After then things may be different.

There is a further difficulty in allowing, not to say encouraging, newly qualified practitioners to take university posts. Recruitment of practitioners into the Services is continuing, and is likely to continue. The only source for recruitment is the young practitioner. This difficulty may not be insurmountable, but it does exist. It must be remembered that any diversion of young practitioners to university or other civilian posts would mean a corresponding retardation of demobilization.—I am, etc.,

PETER MACDONALD,
York. Chairman, Services Committee, C.M.W.C.

Neurologist and Neurosurgeon

Sir,—The Society of British Neurological Surgeons is about to draw up a scheme for the training of the neurosurgeon. I must take the letter by Dr. F. M. R. Walshe and Dr. C. P. Symonds (Sept. 15, p. 364), who will always be heard with respect, as an invitation to express my own views, even though time proves that they do not coincide with the consensus of my brethren.

Your correspondents are concerned about an ideological concept of the neurologist, but since this does not admit of realistic treatment they resolve the problem into a statement of the relative function and required training of the medical neurologist and the neurosurgeon. They regret that the medical neurologist has lost too much valuable clinical material to the latter, and believe that this stunts the growth of the physician. It is a fact that the neurological physician no longer sees each and every case of suspected brain tumour before it goes to the surgeon, as was the custom in former days. It needs little imagination to comprehend that this is disappointing to the physician; but it has happened in many branches of medicine and is a sign of (at least) commencing maturity.

What Dr. Walshe and Dr. Symonds do not say is that the state of affairs which causes them anxiety has not been brought about as the result of a deliberate policy of exclusion laid down, or likely to be laid down, by neurosurgeons, but has occurred as a natural process which needs a new adjustment—that of partnership. I am well aware that the emancipation which the neurosurgeon now enjoys carries with it heavy responsibilities. He is called upon to make the greatest contribution that he can to our knowledge of the nervous system (for which he has exceptional opportunities), and, more important from the humanitarian point of view, to avoid the infliction of unnecessary trauma.

On this latter point Dr. Walshe and Dr. Symonds have a good deal to say. It is true that the neurosurgeon may sometimes apply surgical means of diagnosis too soon; much more often he is called upon to apply them too late. His recollections of such instances are unquestionably an important factor in his occasional unnecessary recourse to his own special methods. However, no one needs to speak of the successes won by these means. Your correspondents adduce certain figures of Harvey Cushing's to show how much clinical material of a non-surgical type may come into a neurosurgical ward and run the risk of being operated on through mistaken diagnosis. On page 6 of the book to which they refer they will find a clear statement as to what comprised a "histologically unverified tumour." It should be borne in mind that the 2,000 tumours which formed the basis of Cushing's review were spread over the years 1901–31—i.e., during the years of growth of knowledge of the natural history of tumours. This was mostly long before the date of pneumography and the like, which Cushing was slow to adopt. It would be unwarrantable assumption that Cushing was not fully assisted in some of his errors as well as in many of his successes by the best available medical neurological opinion of the day. Neither medical neurologist nor neurosurgeon is impeccable, and it would be a fatal error to try to build the future on any other understanding. I do not believe that the idealistic concept of the neurologist set forth in your pages is free from such danger.

What deeply concerns us all is so to educate ourselves and our successors that mistakes shall be minimized. This will be done by the freest possible interchange of opinion between physician and surgeon (and, I would add, sometimes psychiatrist) in neurological material. The loadstone that draws the surgeon into neurosurgery is not surgical technique but neurology. We must do our utmost to see that the younger generation has a balanced training and adequate remuneration to enable a man to obtain it, a vital condition on which many planners are silent. I know from a long personal experience that a happy relationship, mutually educative, to say nothing of friendship, between the medical and surgical subdivisions of neurology is possible, and is, moreover, already exemplified in many neurological centres in this country and elsewhere. Any further schism, if such it be, will be prevented by the development of Regional Neurological Institutes with common laboratories and services, such as is planned for Manchester. No good will come of repressive action in which one branch seeks to dominate the other.—I am, etc.,

Manchester. GEOFFREY JEFFERSON.

Treatment of Duodenal Ulcer

Sir,—I am glad to read Dr. A. H. Douthwaite's vigorous criticism (Sept. 22, p. 400) of this, that, or the other "cure" for duodenal ulceration as an incident in ambulatory treatment. As he points out, inadequate attention to the natural history of the lesion is responsible for much unwarranted attribution, and I am sure he will agree with me that almost incredible remissions are a familiar experience, not only through the apparent influence of such forms of therapy, but even despite what might be stigmatized as a criminal disregard for all orthodox precautions.

If patients (and doctors) are prepared to gamble on the chances of remissions and spontaneous cure there may be no harm in the administration of anything which contributes through its suggestive value. But if such ambulatory treatment is advanced as a reliable substitute for accepted orthodox procedure the danger can hardly be exaggerated, especially as it is only natural that the invitation to a procedure so much less irksome and inconvenient will be warmly welcomed.—I am, etc.,

London, W.1. ALDOPHE ABRAHAMS.

Nerve Injuries in Children

Sir,—I was most interested to read Mr. H. S. Souttar's article on nerve injuries in children (Sept. 15, p. 349). In my limited experience I have had to deal with one such case which proved dramatically the truth of his statements and conclusions.

While acting as R.S.O. at the Bolton Royal Infirmary in 1937 a child was brought in to me one evening with a history that her mother had attempted to kill her by cutting her radial artery with a small knife. The child was aged about 4. On examination there was a small wound over the lower end of the radius, and it was obvious that extensive damage had been done to blood vessels, tendons, and nerves. An immediate operation was performed, and when the wound had been enlarged it was found that, with the exception of the ulnar artery, every single structure on the front of the wrist had been severed. The gash even extended into the pronator quadratus. With some reluctance, as I had seen enough of the sequelae of these injuries to discourage me, I set about the seemingly endless task of suturing all the tendons and the two nerves. I believe it took me well over two hours. The wound healed by primary union and the child went home after a reasonable stay in hospital.

After this I lost track of the case until about a year later I was sent for to the orthopaedic O.P.D. by the orthopaedic surgeon (Mr. S. M. Milner, of Manchester) and asked to examine the child. He asked me what the original injury had been, and I remember he expressed polite disbelief when I told him the extent of the damage. The record card, however, which was produced shortly, contained the notes made immediately after the operation. The child had made a full functional recovery, and the only evidence of what had happened was a transverse scar which was slightly adherent to the underlying tendons.

I can clearly remember the ease with which the nerves were found, and that chiefly by reason of their size; also the difficulty with which the tendons were identified and sutured, so much so that on several occasions during the operation I remarked on the apparent foolishness of the procedure I was indulging in. The result is all the more remarkable if one pauses for a moment to consider the usual aftermath of such an injury in an adult. I think it would be most interesting if others were to recount their experiences in this sphere, as the textbooks, with their usual reticence, have got but little to add to our knowledge of the subject.—I am, etc.,

Tralee, Co. Kerry. M. J. HORGAN.

SIR,—Mr. H. S. Souttar (Sept. 15, p. 349) did well to stress the value of operation upon nerve injuries in children and adolescents. The results in cases at this age are so much speedier and more successful than similar operations performed in adults. The following is a brief case history which illustrates this point.

The patient was a girl, aged 14, who had sustained a complete lesion of the median nerve 20 months previously. The nerve had been sutured at the time, but neither motor nor sensory recovery was evident on examination. The lesion was 1½ in. above the wrist. Operation was undertaken and an inch of scar tissue excised. The freshened nerve ends were sutured, and the limb plastered with the elbow- and wrist-joint in flexion, to relieve tension, for 9 weeks. Return of sensation occurred over the thenar eminence at the sixth week. This was confirmed clinically. The rate of recovery far exceeded 7 mm. a day, being approximately 15 mm. a day. The patient had stated that sensation was returning after 4 weeks, but I did not believe this and failed to examine her at this stage. General sensory recovery had occurred by the twelfth week. By 3 months motor recovery of the thenar muscles was evident, and was well established by 6 months.

No adult case in which the median nerve has been repaired at this site in this peripheral nerve unit has recovered so quickly or so thoroughly; 5 mm. a day is the maximum rate of recovery.—I am, etc.,

E. HAMBLY,
Surgeon E.M.S., Royal National Orthopaedic Hospital.

Action of Rubber on Penicillin

SIR,—The experience of your correspondent F. A. R. Stammers (*Journal*, Sept. 22, p. 400) that synthetic rubber tubing used in a drip apparatus completely destroys penicillin in an hour or two, while natural rubber has almost no ill effect upon penicillin, seems to be at variance with the results of the work of S. T. Cowan (*Lancet*, Feb. 10, 1945, p. 178), whose experimental study of this problem indicates that natural rubber tubing can "in certain circumstances" inactivate some of the penicillin, especially after it has been repeatedly sterilized. Cowan points out that the validity of conclusions drawn from experiments of this kind depends upon the absence of contamination and the accuracy of the penicillin assays. He concludes that during continuous intramuscular infusion there is ample time for the destruction by contact with some kinds of tubing of 25 to 50% of the penicillin. He gives a simple method of testing the effect of rubber tubing upon penicillin.

Clearly there is room for more work on this problem, and it should be undertaken at once. It would be valuable to know, for example, whether any of the tubings now being made from plastic materials for surgical use have any effect upon penicillin. If they had not, these could be used for penicillin administration.

Perhaps I should add that I have myself no experience of the use of penicillin. I have merely had occasion to follow a good deal of the literature on penicillin, and Cowan's paper and Stammers's letter are the only ones on the effect of rubber on penicillin that I have seen.—I am, etc.,

Cambridge. GEOFFREY LAPAGE.

Air Embolism

SIR,—Dr. P. H. Dalgleish (Aug. 25, p. 256) gave an interesting account of two cases of air embolism, both having occurred during refills. It may be of interest to remember that Dr. Clive Riviere, in his book *The Pneumothorax Treatment of Pulmonary Tuberculosis* (1st edition), written as long ago as 1917, states that most of the recorded cases of fatal gas embolism have occurred at refills and not at the initial operation. He also states the chances of gas embolism are increased by the use of tubing of too wide a bore, and he advised an internal diameter of 4 mm., and (p. 68), under refills, his instructions are: "Where a manometer reading fails at a refill, unless due to a blocked needle which can be cleared by a suitable stylet and a clear reading thus obtained, the needle should be withdrawn, resterilized, dried, and entered elsewhere."

Riviere's six rules for the prevention of air embolism stand the test of time. His Rule 6 is, "Do not use rubber and manometer tubing of needlessly large bore, nor have tubing of needless length." To his Rule 5, "Never pass a blunt stylet for clearing the needle without the use of stuffing box or rubber cap," I would add, "Make sure that the stylet does not project beyond the needle opening but is just the correct length and shape to plug the opening." Nurses occasionally mix up stylets, and I have seen many misfits and been presented with an apparatus with delivery tubing 6 ft. long.

Every possible precaution to avoid the dangerous results of lung puncture and air embolism has to be taken before any induction or refill. This takes time. Riviere's book perhaps gave fuller and better instructions on the actual technique of A.P. work than many later authors, and I believe many present A.P. workers would still find his book very helpful, although naturally in parts it is out of date. It was a very practical and wonderful book, and the first on A.P. treatment in our language, so that I think it deserves to be regarded as a classic. It certainly was an excellent guide and vade-mecum to many who started doing A.P.s in the early years of this century.—I am, etc.,

A. NIVEN ROBERTSON.

Stovaine Anaesthesia

SIR,—Spinal anaesthetic drugs are considered heavy or light as compared with the specific gravity of the cerebrospinal fluid, which ranges between 1.003 and 1.007. Stovaine ampoules which are available in the market are Barker's and Chaput's, the specific gravity of the former being 1.025 and of the latter 1.080. Both are, therefore, definitely heavy, as well from the clinical findings as by virtue of their specific gravity. If the injection of stovaine is given with the patient in the sitting position, even between the second and third lumbar vertebrae, it at once gravitates down to the lowest part of the spinal column and into the sacral canal, and quickly settles down there in less than a minute and readily gets fixed. It is then difficult to get the solution to move upwards to affect even the lowest lumbar nerves, if there has been a little delay in making the patients lie down.

In a considerable number of cases it has been observed by me that even if the table is later on tilted in the Trendelenburg position, slight or steep, the stovaine solution afterwards does not move towards the head. This proves that stovaine is heavier than cerebrospinal fluid. It is therefore regrettable that in certain popular textbooks, particularly in *Manual of Surgery* by Rose and Carless, it is stated: "It can be used as either light or heavy solution." It needs to be pointed out that even when dissolved in alcohol the sp. gr. is not definitely lightened, and it cannot be safely treated as a light solution. Hence students are misled about the properties of stovaine, and some surgeons are also not sure of the qualities of stovaine, and so might meet with a disaster. It should be definitely stated that stovaine always forms a hyperbaric solution. The maximum dose mentioned as 0.8 c.cm. can be exceeded. It is also stated: "It tends to give a rather big fall in blood pressure"; but it is not explained that this can be prevented or lessened by vasoconstrictors and other means.

In final M.B., B.S. examinations the students have been answering, if asked about stovaine, that it could be either light or heavy, and quoting the authority of Rose and Carless; so the examiner has to agree and mark them right. This is, therefore, to draw the attention of the authors and others to this wrong impression produced on the readers. Incidentally it shows the necessity for the lecturer in anaesthetics being appointed an additional examiner for at least viva-voce examination in anaesthetics in the final M.B., B.S., as at present the surgeons, who generally know precious little about the subject, pose before the candidates as experts in anaesthetics also, and the anaesthetist is deprived of his right as an examiner in the subject.

The toxic effects of stovaine together with the nerve-destructive action of alcohol would make the solution very undesirable for use in operations, and, in fact, an alcoholic solution should be condemned as a spinal anaesthetic with whatever drug it is used.—I am, etc.,

Lahore. K. E. MADAN.

Rehabilitation of Fractured Limbs

SIR,—In the *Journal* of Sept. 8 (p. 332) there appears a short letter from Dr. R. Murray Barrow of the greatest importance. In one pregnant sentence—"the putting of fractures into plaster, leaving the soft tissues immobile for several weeks"—he exposes a disastrous turn of medical practice. I now shortly recount a few of the shocking results encountered in my practice.

(1) A woman of 55 with a tibio-fibular fracture close to the ankle was fitted in a London hospital with a tight plaster for weeks; when removed so shocking a position was disclosed that operation was required; result: death of the foot, amputation below the knee. (2) A street accident; simple fracture of both bones about 4 in. above the ankle was put in plaster; later, gangrene of the foot, amputation below the knee. (3) Colles's fracture in plaster for weeks; when released, semi-paresis of the arm; never recovered. (4) An old lady was knocked off her bicycle by a lorry, and her arm was fractured midway between wrist and elbow; for weeks it was in plaster, and when released was so weak and painful that she scarcely slept; at subsequent operation the median nerve was found to be held down by adhesions.

Under first-rate guidance with continuous watching good may be done, but as a common practice the results are terrible to contemplate. Your correspondent most truly writes: "The modern method seems to me to be distinctly retrograde and entails weeks of convalescing after union."

I was house-surgeon at Guy's 50 years ago. Arm fractures were splinted; femurs were fixed up with Hodgen's splints; fractures below the knee were all treated in Croft's splints—that is, two separate segments of flannel impregnated with plaster-of Paris held together by starch bandages, which were cut two days later and the plaster cast secured by bandages then. The modern craze for restoration of a limb to the "precise line" neglects the need for restoring the limb to use as quickly as possible. Surely a slight displacement of bone or a "hob" is a very small matter compared with loss of a limb or of function for months or years. With Colles's fracture the wrist was moved at least three times a week and the arm restored to use in about a month. The legs in the Croft splints were moved about in 10 days or so, after the bones were united, which, in my experience as house-surgeon, always occurred in under a fortnight.—I am, etc.,

Tilford, Surrey. VAUGHAN PENDRED.

Mediastinal Emphysema after Tracheotomy

SIR,—The *Journal* of July 14 has just reached me in Košice, Eastern Slovakia, and I read with interest the memorandum by Mr. J. R. M. Whigham on mediastinal emphysema and bilateral pneumothorax after tracheotomy (p. 47). In this connexion the following notes might be of some interest.

An epidemic of diphtheria has been spreading in this region. There have been many severe cases of laryngeal diphtheria, some requiring tracheotomy. An 18-months-old boy was brought in suffering from diphtheria of the tonsils and the larynx. Tracheotomy was performed soon after admission for acute asphyxia. Breathing improved, but he died 6 hours later. The necropsy showed: (1) widespread swelling of the face and neck due to subcutaneous emphysema; (2) extensive mediastinal emphysema covering the heart, that looked as if it were bathed in soap bubbles; (3) thick diphtheritic pseudo-membranes covering the epiglottis and the mucosa of the larynx blocking the air passage; (4) purulent bronchitis and bronchopneumonia of the lower lobes of the lungs.

Subcutaneous and mediastinal emphysema is not very rare after tracheotomy and is due largely to technical reasons. Mr. P. Steiner, F.R.C.S.Ed., senior surgeon, General Hospital, Košice, points out that it is unavoidable for some air to leak out between the cannula and the edges of the tracheotomy opening in the trachea. If the skin were tightly closed round the cannula the patient would press air into the tissues when coughing or breathing forcibly. This could be avoided by not suturing the skin tightly round the cannula so that air escaping from the tracheotomy wound could get away freely.—I am, etc.,

I. FRIEDMANN,
Pathologist, 1st Czechoslovak Medical Mission from England.
General Hospital, Kosice.

Acute Inversion of the Uterus

SIR,—I would like to add my experience in a case of acute incomplete puerperal inversion of the uterus in support of the simple method of replacement under hydraulic pressure described by Mr. J. V. O'Sullivan (Sept. 1, p. 282).

The patient, a primipara aged 35, was admitted to our maternity department in a condition of severe shock after a forceps delivery outside. Credé's expression had been attempted unsuccessfully for post-partum haemorrhage. On arrival the patient was extremely pale, collapsed, restless, and almost moribund. Her pulse was not perceptible and her blood pressure could not be recorded. She complained of severe lower abdominal pains and made efforts to expel the retained placenta. Treatment for shock was instituted. Abdominal examination revealed a deep funnel-shaped excavation where the fundus should have been. There was moderate vaginal bleeding and the ligated cord was protruding from the vagina. The perineum showed a deep laceration extending into the sphincter ani.

Forty minutes after admission the patient showed improvement from her almost moribund condition. Soon afterwards she started bleeding freely again, so I was forced to perform a manual removal of the placenta under light general anaesthesia. Vaginally, an incomplete inversion of the uterus was confirmed. The placenta was adherent to the apex of the inversion and was stripped off easily. On the advice of Mr. O'Sullivan I employed the method he recommended. A warm "dettol" douche, from a douche-can 2½ feet above the level of the patient, was run into the vagina with a Bozeman catheter and the vagina ballooned out. The right forearm blocked the vulva. It was interesting to feel how the over-distension of the vagina with the fluid caused the dilatation of the constricting cervix. Gentle digital pressure against the inverted fundus, together with the fluid pressure, replaced the uterus with ease in a very short time. The complete perineal tear was sutured speedily. After reposition and further shock therapy, including methedrine 30 mg., the patient improved dramatically. She made an uneventful recovery, and was discharged in perfect health on the 22nd day after delivery.

There must be several such serious cases annually in every country. O'Sullivan's simple method meets the desperate situation better than any other I have known; to encourage its further practice and lower the present high mortality I considered it most important that this further case should be reported.—I am, etc.,

WALTER SPITZER,
Senior Obstetrician and Gynaecologist, Kingston County Hospital, Kingston.
Kingston-on-Thames.

Toxicity of Magnesium

SIR,—May I be allowed to answer your annotation (Sept. 22, p. 393) on this subject. I believe I was the first and original proposer of intravenous injection of magnesium sulphate for angiospasm (*Lancet*, 1933). Since then I probably performed more than a thousand of such injections without any distress or alarm to myself or to the patient. Briefly the rules are: start with the patient in a recumbent position; never use a solution more than 10% in strength; add glucose; start with 1 gramme of magnesium.

So far as I know, in one of the voluntary hospitals an elderly patient died during the intravenous injection of magnesium; he suffered from coronary sclerosis. I do not know if all of the above-mentioned precautions were observed. Nor did I have any complications with intramuscular injections, providing the strength is 10%. It is very well tolerated.—I am, etc.,

London, E.1. N. PINES.

Chronic Pulmonary Tuberculosis

SIR,—The primary tuberculous infection of the lung does not usually lead to this form of disease, though it may break down with the formation of pneumonic tuberculosis, which can persist into the chronic stage. I have seen one such case in an adult and three in children during the present year. Usually the primary infection is recovered from. Later, due to reinfection or breakdown from an apparently healed lesion, when circumstances are suitable, chronic pulmonary tuberculosis begins.

I was interested to discover whether a patient who becomes cured can ever get the disease again. After five years' experience in large sanatoria (300 and 500 beds respectively) and five years' dispensary work at five busy tuberculosis dispensaries in an area with a population of 250,000 I am still unable to give a definite answer. Of course, few patients recover so completely that there is no remaining *x*-ray evidence of disease. I have, however, seen two such cases in the last year. Usually cure is shown by fibrosis and calcification. When cure is thought to be certain, live tubercle bacilli may persist even in calcified foci (Pagel). So difficult is the problem of deciding when a case is cured that guidance is provided in Ministry of Health Memorandum 37 T. revised, as follows—*Quiescent:* No clinical evidence of activity, and any signs present are compatible with a healed lesion. *Arrested:* A lesion quiescent two years. *Recovered:* Arrested three years. Only then may a case be removed from the register. Statistics show that if a patient has been apparently cured for five years, then he is likely to remain so. Pottenger years ago arrived at a similar conclusion.

Now, disease may be "arrested" with either little or gross *x*-ray evidence. In the latter case it is of course not possible to be certain the disease is in fact healed: it is more than likely that active lesions are shut off from the rest of the lung by fibrous tissue. Of the few cases returned to the register during the last five years the majority would come into the above category. Two patients who were returned to the register with active lesions had been classed as recovered when taken off the books. Unfortunately these two cases were diagnosed in the days before *x* rays were in universal use. As their sputa had never contained tubercle bacilli it is impossible to prove the original diagnosis.

I have searched through thousands of records and *x*-ray films in pursuit of a recurrent case of pulmonary tuberculosis of the adult type. In conclusion, I have to admit that I have yet to come across such a patient. As a "recovered" case rarely breaks down, a patient whose disease is actually cured probably has such a high resistance to disease that he will never suffer again from this scourge of mankind.—I am, etc.,

Pontefract. C. PONIEDEL, M.B., Ch.B.

B.L.A. Surgery

SIR,—The authors of the excellent article on B.L.A. surgery (Sept. 22, p. 377) repeat an error (non-medical) when they state that Walcheren was captured by the Canadians. This "toughest of small amphibious operations" was carried out in grand style by the 52nd Lowland Division under Gen. Hakewill-Smith, attacking across the Scheldt and along the causeway. I happened to be present in a passive role and can testify to the excellent work under terrible conditions done by the medical units and R.M.O.s of that division. It is only right that they should have the credit.—I am, etc.,

"EX-A.D.M.S."

Safe Milk

SIR,—I have just opened the *Journal* of Sept. 8 with Dr. D. J. Gair Johnston's most pertinent plea (p. 330) for the domestic sterilization of milk. But he omits to mention the weightiest reason for preferring the method—which is that it greatly increases the probability that the sterilized milk will still be sterile when it is drunk. It is too often forgotten that the attendants at pasteurization plants are not bacteriologists. A colleague told me that he had been taken to see a machine which poured the sterile milk into the bottles and covered them automatically with a sterile cover. The bottles were sterilized in a separate machine and fed into this pasteurization and bottling apparatus by a boy, who picked them up three at a time, with one dirty finger in each of two and a dirty thumb in the third. Within the last few years I have myself had pasteurized milk, delivered at my house, go sour within twelve hours in cold weather in the unopened "sterile" bottle; but of course with pasteurized milk there is no guarantee that lactic acid will appear as a danger signal as the flora multiply.—I am, etc.,

C.M.F. N. P. BRUCE.

Doctors and the Social Trend

SIR,—At the ninth International Congress on Dermatology, held in Budapest in the autumn of 1935, I was chairman of the sixth commission, dealing with general medical problems. One of these was whether "socialization of medicine is desirable." The Congress attracted over 1,000 members from every part of the civilized world and there was a very representative gathering of delegates to discuss this question. A "good round no" was recorded by all the delegates except the three coming from Russia, and the dislike of socialization was especially marked in those countries, outside Russia, in which the experiment had been tried.

We are informed by Dr. P. G. S. Davis (Sept. 22, p. 405) that of the thirteen medical M.P.s in the present Parliament eight are members of the Socialist Medical Association. This association has been described by its president in a letter to the Press as a "solely political organization." I am informed that its medical membership is less than 1% of the whole body of practitioners on the British *Medical Register*, contrasting in this respect with the membership of the B.M.A., which now, it is stated, represents a membership of something like 75% of the registered profession. The present Government will doubtless accept its medical guidance largely from the Socialist Medical Association, which is in effect an annexe of the Socialist Party, and it is important for doctors to realize that political and not medical considerations will be the motive of the changes in medical practice which, it is said, form part of the programme of the Socialist Party. That political aim may, I think, be summed up as the pursuit of "social equality," to be achieved, if it is indeed at all possible, by achieving uniformity at the lowest existing level.

That has been, I submit, the aim and, already in some measure, the effect of the Education Act, which is floundering helplessly towards a standstill by reason of the critical shortage of teachers. It is not, I think, altogether surprising that the Minister of Education in the late Government seized the first opportunity of exchanging his post for another department in the short-lived "caretaker" administration. For fulfilment of the promises of the Act from 70,000 to 100,000 new recruits to the teaching profession are called for. To meet this demand Mr. Butler *two years ago* inaugurated a scheme of emergency training of teachers by which recruits after one year's training and without passing any examination would be introduced into the schools as "qualified teachers." The present position of this supply was described in a recent answer to me (*Hansard*, Aug. 22, 1945): "18 teachers so trained have been admitted to the schools and 360 are in training." It is a simple arithmetical calculation to forecast how long it will take at this rate to meet the demand!

The supply of doctors to work the proposals of the White Paper, it has been calculated, would have to be three times as large as the present available total of qualified practitioners, and doctors, I submit, cannot be improvised on the same lines as have been proposed for teachers. During one of the debates on the health services a "back-bencher," on the Socialist side urged the Minister of Health to side-track the doctors and proceed with his proposals without their co-operation, but whether the public will be satisfied with any such solution is quite another matter.

The position of medicine in Soviet Russia is extremely difficult to ascertain because of the "iron curtain" (as Churchill called it) which shuts out Russia and countries occupied by it from observation by the rest of the world. But the position of research in medicine as well as in general science is, I would suggest, a reliable index of the position of both medicine and science, and publicity for research is clearly an aim of Soviet Russia. An analysis of that position in various countries has been offered in a recent publication (*Science and the Planned State*) by Dr. J. R. Baker, lecturer in zoology in the University of Oxford. On that analysis Russia is by far the most backward of all European nations in research both in medicine and in science. By this argument socialization of medicine, in force in Russia for more than two decades, has conspicuously failed. —I am, etc.,

House of Commons. E. Graham-Little.

Training for Released Service Doctors

Sir,—Mr. H. S. Souttar in his Presidential Address before the B.M.A. on the return of the doctor (*Journal*, Aug. 4, p. 163) refers to the scheme for training released doctors. His Class III provides for men who wish to hold registrar jobs, for which they will receive £550 a year. There are many M.O.s who are keen to undertake such work in the near future and have been seeking advice about the best centre for which to apply. But are these posts available? It seems to depend on who is paying for the scheme. If the Government pays for each registrar, the teaching hospitals will no doubt accept a considerable number and may be able to provide for all the applicants. If, however, the medical schools are expected to provide the funds from their own grants, it seems unlikely that the required number of such posts will be available.

As this is an urgent problem and one is being asked about it by those who are soon to be released, could some authoritative statement be issued so as to avoid a lot of keen young doctors being disappointed?—I am, etc.,

F. F. Hellier,
Lieut.-Col., R.A.M.C.

Bitterness

Sir,—Major H. B. Stallard's letter (Sept. 22, p. 407) comes like the calm voice of reason amid the cacophonous sounds of a family squabble. Those who, like myself, saw the war coming, joined the Territorial Army or the equivalent, and served throughout all or most of the time in field units, have no wish to fling away in bitterness what they have gained by seeing where their duty lay and doing it.

Maybe we have lost professionally; maybe we can never hope to compete with our brethren who stayed on at hospital and rose through higher degrees to junior honorary posts. But a man cannot have everything in life; and where we have lost on the one count, perhaps we have gained something in the sphere of less ponderable qualities. Certainly, speaking for myself, I feel I have gained something which I find it hard to define; perhaps it is most closely related to what I have seen of self-sacrifice and the "mucking-in" of the ordinary soldier for the common good.

I shall always remember the words of a friend, written to me shortly before he was killed, in answer to a rather carping letter of mine: "Don't let's spoil the first fine careless rapture of having been in from the beginning by calculating now whether it was worth the cost or not." A man is a certain kind of person, who does certain kinds of things. Bitterness that those things do not always bring in the kind of return we should like will get us nowhere. Therefore, thankful that my lot has not been, as Major Stallard tells us, the sea, six feet of African sand or European earth, I and, I think, very many of my fellows are content to do some good where we find it to be done, without bitterness or malice towards our more highly qualified contemporaries.—I am, etc.,

J. M. G. Wilson.

Sir,—In the *Journal* of Sept. 22 (p. 407) there is a timely letter from Major Stallard. As he says, there is much bitterness felt by Service medical officers, and the bitterness is too often more than justified. For a long time now your correspondence columns have carried letters complaining of the utter wastage of medical man-power in the Services, the hardships and gross overwork of general practitioners, and the relatively fortunate position of the young specialists in E.M.S. hospitals. These are facts, and bickerings among ourselves will not alter them. Our only hope is in closer unity, preferably through the B.M.A., whose greatly increased membership during the war shows that most of us do want some central medical body to which we can give loyalty in exchange for the strongest possible presentation of our cause, anywhere and always.

Major Stallard was fortunate in spending nearly half his service in hospital. For seventy-three barren months this had eluded me and many of my colleagues. The time wasted on so-called sanitation, administration, and stores accounting is a dead loss and must be written off as an offering to the war effort; perhaps it might rank as honourably as a minor wound. At least these things were done, and it is better that they should be done by a doctor than left undone. The folly of wasting doctors on such work is not ours. Stallard's experience in meeting fine men has been mine also. A medical officer meets high and low alike, and I have had the privilege of serving with some of the finest men and women imaginable. High among these I would place my own colleagues. They also were usually on uncongenial work, but, as a rule, they have done that work well, and shown professional skill, friendliness, and ethical conduct, which made the fact of our meeting transcend the circumstances. These doctors have been Naval, Army, and Air Force, British civilians, and medical officers of the American, Canadian, Australian, South African, and Polish Forces. Many times have we exchanged grumbles about our several lots, but we have worked and played together in harmony.

I suggest that as each is released he should become an active member of his local Division of the B.M.A., and make known to his representative just what he thinks can be done to make Service medicine attractive. If this were done, your committees would receive all the constructive ideas bred of our individual search for better things; and a strengthened Association could put before the Government a scheme for a medical service so good that the competition would be to get into it, not out of it. Unanimous support for our own Association would greatly improve our professional relations with each other, and would forestall any measures of coercion based on lack of unity.—I am, etc.,

Waterbeach, Cambridge. J. L. Brown,
Squadron Leader, R.A.F.

Infant Mortality and Social Conditions

Sir,—The leading article in your issue of Sept. 22 (p. 392), headed "Infant Mortality and Social Conditions" is mainly occupied with comments on a recent paper (Woolf and Waterhouse, 1945) of which I am senior author. Every statement it makes about our paper is untrue and worded in the way most calculated to arouse prejudice in the mind of the medical reader. To prove this it is only necessary to give parallel quotations. Your contributor writes:

> "Apparently public health workers and authorities have deluded themselves for years by assuming that infant mortality was influenced by complex factors and that medical science and improved mothercraft could affect this rate."

Nothing could be more calculated to antagonize medical men than the insinuation that we regard their devoted efforts as of no value. But the truth is that we give a detailed discussion, including six diagrams, of the fall in infant mortality over the past 70 years, that we pay a well-deserved tribute to the fight for maternity and child welfare put up by the late Sir Arthur Newsholme against the obscurantists of his day, and that we clearly state this conclusion:

> "The whole improvement can be attributed to such things as better housing, feeding, mothercraft, and sanitation, reduction of the virulence of pathogens, and so on—all those agencies covered by the word 'environment' when it is used in opposition to 'heredity'."

Again, your contributor writes:

> "Between 1911 and 1931 the infant mortality of Social Class V was halved, due, the authors state, to improvement in environment. The mortality of Social Classes I to IV also declined at approximately the same rate, and it seems more reasonable to suggest that a factor independent of social class was responsible for a large measure of this improvement."

In our paper we give a vivid diagram and a detailed discussion of the fall of infant mortality in all social classes, and the effect is plainly ascribed to "such things as more adequate public health measures, more efficient choice of foodstuffs, better mothercraft," all of which are improvements that manifestly apply to rich as well as poor.

Your contributor pours heavy scorn on our conclusion that a rate of 23.1 could be attained by the elimination of deleterious environmental influences. Yet he himself points out that the present rate, for 1944, is 46, and also states that "it is generally acknowledged that a further reduction is possible, probably to one-half of the present rate." One-half of 46 is 23. That is the very figure that emerges from our statistical analysis.

Your contributor quotes our conclusion that many infant deaths are associated with four social agencies—overcrowding, low-paid occupations, unemployment, and industrial employment of women. He casts doubt on these results, "since in 1943 and 1944, when enemy action had made the housing position worse and the employment of women in industry was on a higher scale than ever before, the figures for infant mortality were 49 and 46, the lowest values ever recorded in England and Wales."

Your contributor says that "strict objectivity is needed." It certainly is. We specified four social factors. During the war two got worse—overcrowding, and work by women. Your contributor mentions these. But how about unemployment, which was completely eliminated? How about wage rates? During the war, what with the levelling up of the pay of the lowest-paid workers, what with extensive overtime, and what with the extra milk and dietary supplements available to all babies and to pregnant and nursing women, the nutritional level of the baby in the poorest home was probably raised to a level similar to that of the highest-paid workers before the war. Low wages as a causative factor in infant mortality can be regarded as having been virtually eliminated. In his zeal for "strict objectivity" your contributor chooses to ignore both unemployment and wage levels. Overcrowding and work by women have got worse, and unemployment and low wages have been knocked out. The net result is a fall in the rate from 61.7 (the average for 1928–38, to which our calculations relate) to 47.5 (the average for 1943–4), being a decline of 14.2. Here is a useful test of our quantitative conclusions. Let us see how they fare.

In our paper we give the following estimates of the reductions in the rate to be expected by complete elimination of the poverty symptoms concerned: overcrowding, 13.8; unemployment, 8.0; low wages, 10.3; work by women, 5.3. Elimination of unemployment and low wages would give an expected reduction of 8.0+10.3, which equals 18.3. There are good reasons for supposing that the rises attributable to housing and work by women will not be very big.

Overcrowding.—The destruction of houses can be partly offset by the absence of a large part of the population on war service. Probably more important is the effect of evacuation. Infant mortality in big towns before the war averaged more than 10 points above the rural rate. A substantial proportion of babies were withdrawn to the country, reducing their mortality risk by a figure of this order. On housing, the pluses and minuses probably pretty well cancel out.

Work by Women.—The deleterious effect on the infant was largely due before the war to lack of care while his mother was at work. Wartime nurseries and other arrangements minimized these dangers for babies of munition workers; and, in any case, pregnant and nursing women escaped industrial conscription.

The summing-up is as follows:

Expected fall by elimination of unemployment and low wages	18.3
Observed fall	14.2
Attributable to worse housing and work by women ..	4.1

I think any reasonable person will agree that our peacetime analysis passes with flying colours the test of extrapolation to wartime conditions.

One final sample of your contributor's methods. He writes: "They were, apparently, so enamoured of their lengthy arithmetical processes that they overlooked the first lesson in statistics—i.e., that correlation is not necessarily causation." Your contributor falters in his quest for "strict objectivity." For the facts are that we did not venture to use our regression equations as the basis of social or medical conclusions until we had carefully examined every reasonable objection to their validity. The greater part of our first section is taken up with eliminating the possibility that our effects are due to hereditary differences in viability at different social levels. In our fourth section we critically examine our social indices with respect to their accuracy and relevance. In our seventh section we discuss seriatim the statistical and social objections that might be advanced to regarding our equations as a valid description of the phenomena under discussion. Only after a full examination of possible contraindications do we proceed to draw up a final balance-sheet.—I am, etc.,

Alien Doctors

SIR,—Copies of the *Journal* take some time to arrive in India, so this letter will appear somewhat out-dated. I have followed with interest the correspondence on alien doctors practising in Great Britain, and would like to voice the great anxiety felt by members of the profession over-seas about their continued presence in the United Kingdom now that hostilities have ceased. The feeling is that, unless the Government asks them to leave now, they will become so firmly entrenched that they may become a permanency.

In spite of the views expressed by Capt. Joseph (July 14, p. 66) it is well known that a very large number are entrenched in and around Harley Street and all over London, and that of these a disproportionately small number have featured in the Services during the war. Incidentally, Capt. Joseph's attack on Dr. Wm. A. O'Connor and on Irish doctors generally was greatly resented here, where many Irish doctors from both Eire and Great Britain have volunteered for service and have done excellent work. I am not Irish, so I speak without bias.

I hope you will publish this letter, which represents the views of many Service doctors in Burma and India with whom I have discussed the matter.—I am, etc.,

JOHN NESFIELD,
Deolali South, India. Capt., R.A.M.C.

An Institute of Medical Photography

SIR,—The article on medical photography in hospital (Sept. 8, p. 328) will be welcomed by all who are interested in photography. While agreeing with the urgent need for a body such as the proposed "Institute of Medical Photography" I would point out the undesirability of unnecessary duplication of institutions devoted to photography. The Royal Photographic Society is a national body whose aim is the advance of photography in all its aspects, and at the present time it has under consideration the formation of a group devoted to medical photography. I would suggest that before an independent Institute of Medical Photography be inaugurated, the possible advantages of functioning as a group of the Royal Photographic Society should be investigated.—I am, etc.,

H. BAINES,
President,
16, Princes Gate, S.W.7. Royal Photographic Society.

SIR,—While endorsing a few of the statements mentioned in the article on medical photography in hospital, I would like to point out a few facts, which, from personal experience as well as experience of others, I would like your correspondent and others interested in medical photography to know.

To say "the first thing needed for a medical photographic department is a complete system of air conditioning" is absurd. The first thing needed is a competent photographer. Equally so it is absurd to employ the staff recommended. There is not the slightest use trying to send patients away to some other place to have their photographs taken; either they cannot or will not go. Quite a lot of work is urgent and requires a photographer to be always on the spot. An institute of medical photography would no doubt be very desirable, but is there any need for yet another such photographic organization, when already three bodies exist in the Royal Photographic Society, the Association for Scientific Photography, and the Institute of British Photographers? If mobile units are to go "wherever they are wanted" is this the most economical and efficient way?

What is most urgently required is a powerful aid towards trying to get hospitals to provide a competent photographer with the necessary apparatus and accommodation, rather than writing about "utopian schemes" such as those indicated in the article in question.—I am, etc.,

H. Mandiwall,
Chairman, Medical Group, Association for Scientific Photography.
Tavistock House North, London, W.C.1.

Medical Supplies for Singapore: An Appeal

Sir,—Singapore has fallen and the aftermath of war must now be fought. The Japanese (or Nipponese as we call them in the Far East) did literally nothing for Allied prisoners of war, internees, and the local population. I spent a week in Singapore while serving in H.M.S. *Sussex*, so my information is first-hand. By the time this letter is published the majority of Allied prisoners and internees will have left, but the local civilians remain and are being looked after by former internees who have volunteered to stay. The chief of these is the Anglican Bishop of Singapore, and he has arranged for the distribution of any medical supplies that may be sent. Malaria, dysentery, beriberi, pellagra, other deficiency diseases are but a few of the many diseases present. As an illustration of how rampant some diseases are: there is among the local population 80% chronic malaria and 1,000 fresh cases a month. Many need urgent attention, which only the necessary medical supplies can ensure. You can make no finer contribution to their welfare than by aiding the work of the Bishop of Singapore. Many are the humane calls made upon the good in heart, so may I appeal to institutions and individuals for any drugs they can spare, especially those used in the treatment of the diseases mentioned above? Please send them direct to the Bishop of Singapore, The Cathedral House, Singapore, who will be more than pleased to receive them.—I am, etc.,

Iain M. MacLean,
Surg. Lieut., R.N.V.R.
Admiralty, S.W.1.

The Services

Major (Temp.) R. Stuppel, R.A.M.C. (died of wounds), has been mentioned in dispatches in recognition of gallant and distinguished services in the field.

Capt. A. W. Lipmann-Kessel, R.A.M.C., has been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services in the field, and has been awarded the M.C. in recognition of gallant and distinguished services at Arnhem.

Lieut. E. Gartside, R.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services in the defence of Calais in May, 1940.

Acting Wing Cmdr. J. P. Huins, O.B.E., A.F.C., A.A.F., has been awarded a Bar to the Air Force Cross, and Acting Wing Cmdr. R. H. Winfield, D.F.C., A.F.C., R.A.F.O., has been commended for valuable service in the air.

The following appointments and awards have been announced in recognition of gallant and distinguished services in Italy:

C.B.E. (Military Division).—Brig. (local) H. C. Edwards and Col. (Temp.) T. D. Inch, O.B.E., M.C., R.A.M.C.

O.B.E. (Military Division).—Col. (Temp.) J. Kinnear, T.D.; Lieut.-Cols. (Temp.) W. N. J. Clarke, R. T. Grant, J. A. MacDougall, F. H. Taylor, A. W. S. Thompson, and E. S. Watson, R.A.M.C.; and Col. (Temp.) Dev Datt, I.A.M.C.

M.B.E. (Military Division).—Majors (Temp.) J. Leiper, K. C. Mallen, E. L. May, E. R. R. Mellon, A. S. Ramsey, and F. E. Wheeler; Capts. I. Camrass and J. McLean; Lieut. J. Hill, R.A.M.C.; and Major (Temp.) L. C. R. Emmett, I.A.M.C.

M.C.—Capts. G. R. Evans and M. S. Howe, R.A.M.C.

The following medical officers have been mentioned in dispatches in recognition of gallant and distinguished services in Burma:

Col. (Temp.) J. P. Macnamara; Lieut.-Cols. (Temp) H. J. Croot, C. L. Hay-Shunker, J. F. Heslop, R. C. Langford, and J. R. Owen; Lieut.-Col. (Acting) J. M. McIntosh; Major G. W. Greig; Majors (Temp.) G. T. Ashley, J. Brown, J. M. Clow, M.B.E., J. O. Collin, T. E. Henderson, E. L. O. Hood, C. H. Hoskyn, G. J. G. Keys, J. D. MacCallum, W. O'Callaghan, and W. H. Wolstenholme; Major (Acting) T. K. Howat; Capts. G. M. Abraham, N. C. Burnley-Jones, M. Caturani, R. G. Forrest, J. B. Great-Rex, J. K. Hampshire, J. Harris, T. B. Harrison, M. H. Hughes, G. Kilgour, H. A. Kreiser, J. K. H. McCullough, P. H. Nankivell, B. Rado, J. H. Rees, R. W. Tibbetts, W. T. Walker, and G. L. Whitmore; Capts. (Temp.) J. M. McLean and J. A. McPherson, R.A.M.C. Lieut.-Col. T. J. Davidson; Lieut.-Cols. (Temp.) V. D. Gordon, W. McN. Niblock, and A. E. Stevens; Major W. C. Templeton; Majors (Temp.) L. M. Kelly, M.B.E., M. K. Krishnamurti, R. I. Krishnaswamy, and G. B. R. Walkey; Major (Acting) J. G. Webb; Capts. B. R. Irani, K. S. Grewal, K. B. R. Rao, L. N. Budhraja, M.B.E., N. N. Narayen, P. Singh, P. C. Nedungadi, S. Ranganathan, and Capt. Nuruddin; Lieuts. D. Barua, P. Gogoi, and R. J. Chandra, I.M.S. Major (Temp.) J. Edwards; Capts. B. G. Kiddle, M.C., M. P. McMurray, M. Imamuzzafar, and R. P. Bhatia; Lieuts. A. Rashid, C. M. Patnaik, and O. P. Trehon, I.A.M.C.

Freed in the Far East.—Lieut.-Col. J. Huston, Capts. R. H. Cuthbert, E. J. Emery, R. L. Lancaster, L. D. Stone, and R. G. B. Young, R.A.M.C.; Fl. Lieuts. A. N. H. Peach and A. F. Rutherford, R.A.F.V.R.

Obituary

ERNEST WARD, M.D., F.R.C.S.

Members of the British Medical Association, especially those engaged in its central work, will learn with regret of the death on Sept. 21 of Dr. Ernest Ward of Paignton, Devon, a familiar figure at its Annual Representative Meetings for fourteen years. For a long time past he had been suffering from a hopeless malady, but he had fought against it with characteristic stubbornness and had continued much of his public work.

Ernest Ward was born in Yorkshire in 1877, the son of Sir John Ward, who was closely associated with the municipal life of Leeds, was twice mayor of that city and one of its earliest lord mayors. He entered Clare College, Cambridge, in 1896, gaining first-class honours in the Natural Sciences Tripos, Parts I and II. He received his clinical training at the London Hospital and qualified in 1903, becoming a Fellow of the Royal College of Surgeons in 1906 and taking the M.D. of his university in the following year. After serving for a time as clinical assistant at the Belgrave Hospital for Children in London and as assistant medical officer, Queen Alexandra Sanatorium, Davos, he settled in general practice in Devonshire. He was proud to be known as a general practitioner, though on some subjects, notably surgical tuberculosis, he was a specialist. For many years he was tuberculosis officer for South Devon. He interested himself in tuberculosis in all its aspects and was president of the Tuberculosis Society of Great Britain and honorary secretary of the Tuberculosis Group of the Society of Medical Officers of Health. His outstanding achievement was the foundation of the Joint Tuberculosis Council in 1924—a body intended to co-ordinate all tuberculosis activities—and he guided its work for 14 years. Many reports of its proceedings issued from his pen, and he was associated particularly with its investigation into the status of nurses engaged in tuberculosis work and in the evidence which it gave before the Royal Commission on Local Government which preceded the Act of 1929. In the Society of Medical Officers of Health, of which he was at one time president, and in the B.M.A., Ward rendered conspicuous service. He was twice chairman of the Torquay Division of the Association, in 1927-8 and in 1940-1, and he served as its representative from 1927 until the early 'forties. He did good work also on some headquarters committees. When the Annual Meeting of the Association was held in his own locality in 1938 he was president of the Section of Tuberculosis. Locally he was held in great esteem by his colleagues, over ninety of whom subscribed to a testimonial presented to him in 1943 on his retirement from the post of tuberculosis officer. He had been president of the Torquay and District Medical Society. In his earlier career he did a good deal of translation; he was responsible for an English edition of Broca's *Ligations and Amputations* and was co-translator of *Urgent Surgery* by Félix Lejars. In 1929 he published *Medical Adventure: Some Experiences of a General Practitioner*, and followed it up the next year with a similar work of professional reminiscences.

On the platform Ernest Ward appeared a somewhat aggressive personality. Debate when he rose was apt to show an acid edge. But to his friends no man was more lovable, and his friends were many. Incidentally they included the birds of Devonshire, on which he was an acknowledged authority. He was president of the Devon Bird-watching and Preservation Society and of the South-Western Naturalists Union.

H. A. GILKES, *M.C.*, M.D.

The death of Lieut.-Col. Humphrey Arthur Gilkes, R.A.M.C., in an air crash was a great loss to the medical officers who served under him in his capacity as Principal Medical Officer of the British Somaliland Military Administration. In the war of 1914-18 he fought as a serving officer on the Western Front, and was awarded the Military Cross and three bars. After the war he studied medicine at Oxford and St. Bartholomew's

Hospital and qualified in 1922. Subsequently he took his M.A., M.D., D.P.H., and D.T.M.&H. He spent most of his medical career in the Colonial Medical Service. He was for a number of years in Northern Rhodesia, and then went to Trinidad as D.D.M.S. In the recent war, after serving with a field ambulance during the advance into the Somalilands and Ethiopia, he was sent to Somalia (the former Italian Somaliland) as A.D.M.S. There he laid the foundations of the civil medical services during a peculiarly difficult time.

Col. Gilkes (writes T. S. E.) was an outstanding personality and a steadfast believer in the potentialities of the Somali peoples. He was single-mindedly determined throughout the nearly five years he served in Somali countries that the Somalis should have a square deal, and particularly that they should have a good medical service. He was always ready to see even the humblest sweeper in the medical department, and to give him a courteous interview. In administration he had the courage to make it his guiding principle that justice to an employee must never be subordinated to administrative convenience. Col. Gilkes had many other sides to his character than the purely medical one: He was a violinist of distinction and was proud of his "Gilkes violin," which was made by one of his ancestors. He had also had two novels published, and was in the middle of a third at the time of his death.

Rather over two years ago Col. Gilkes came to British Somaliland, first as A.D.M.S. and then as Principal Medical Officer. Here he performed the difficult task of piecing together the medical services after the Italian occupation, and expanding them. He also made a singularly complete plan for the future medical development of the country. It was his personal relation with the Somalis which impressed us, who were new to Colonial conditions, so much. He seemed an example of the highest traditions of the Colonial Service, and it was surprising how many nomadic Somalis whom one talked to in the bush would know the "General daktari," as he was called. It will be a great loss to the country that he has gone while he was still at the beginning of his work here.

Dr. JOHN MATHESON died at Plockton, Ross-shire, on Aug. 30 at the age of 81. He was born at Plockton on Oct. 1, 1863, and attended school there. The present schoolmaster, addressing the pupils after his death, said, "In the passing of Dr. Matheson Plockton School has lost a life-long friend. He was one of Plockton's most distinguished pupils, and it was in keeping with his kindly nature that he should choose for his life work the alleviation of suffering." In 1884 he entered Aberdeen University with the intention of becoming a teacher, and graduated M.A., having won prizes in Greek, Latin, English, and moral philosophy. A year, however, spent in teaching decided him that that was not his *métier*, and he returned to the university to study medicine. He had a brilliant career in medicine, obtaining prizes in botany, junior and senior anatomy, practice of medicine, and medals in chemistry, physiology, operative surgery, surgery, and medical jurisprudence. He qualified M.B., C.M., with highest honours, in 1893. After serving as house-surgeon and house-physician in Aberdeen Infirmary and doing sundry locums, he went in 1894 to Greenwich as assistant to the late Dr. McGavin, later to become partner, and on McGavin's death his successor. For 40 years he carried on practice in Greenwich and Blackheath until he retired in 1934. He joined the B.M.A. in 1910 and was chairman of the Greenwich and Deptford Division, 1931–3. A keen Celt, he was an active member of the Caledonian Medical Society, and president in 1932–3 when the Society met in Windermere; "The Celtic Empire and its Decline" was the subject of his address on that occasion. On giving up practice he retired to his estate, Rudha Mor, Plockton, in the land of his birth. Here, looking over Loch Carron to the mountains of the north and to the Cuillins of Skye and the misty isles in the west, he spent the remainder of his days; happy in looking after his farm, entertaining his friends, and taking a lively interest in local affairs as a member of the district council and active member of the kirk. He was frequently called on, and always willing, to relieve practitioners in the district, and, being well known to the people, was welcomed by the patients. He was a man of decided opinions and dearly loved an argument. Widely read and possessed of a retentive memory, his conversation was always interesting and instructive. Dr. Matheson was predeceased by his wife in 1940, and suffered another grievous loss when his younger son, an officer of the Seaforths, was killed in Madagascar. He is survived by a son, Ian H. Matheson, F.R.C.S., a surgeon with the L.C.C., and three daughters. The funeral was attended by many of the neighbouring lairds and a large number of the people. After the service, partly in Gaelic, which was conducted in the open in front of the house, the coffin was carried through the village, each of the mourners alternately acting as bearers. A most impressive service.—G. W. M.

PROMOTION OF DENTAL TEACHING AND RESEARCH

To promote dental teaching and research the Nuffield Foundation has decided to make grants totalling £9,000 a year for 10 years to the Sutherland Dental School, the University of Durham; the University of Leeds Dental School; the Turner Dental School of the University of Manchester; and Guy's Hospital Dental School. In addition the Foundation is instituting Nuffield Dental Fellowships to an annual value of between £400 and £800, "to improve the supply of dental research workers and teachers." The fellowships will be awarded for one or more years; as a rule not longer than three years. Finally, the Foundation will make scholarships available to provide tuition fees and a subsistence allowance of not more than £200 a year. The scholarship will normally be tenable for only one year, but may be renewed for a second. Forms of application may be obtained from the Secretary of the Nuffield Foundation, 12–13, Mecklenburgh Square, London, W.C.1.

Universities and Colleges

UNIVERSITY OF LONDON

Mr. J. Z. Young, M.A., F.R.S., has been appointed to the University Chair of Anatomy tenable at University College as from Oct. 1. He is a Fellow of Magdalen College, Oxford, and university demonstrator in zoology, and since 1940 has been a member of the Nerve Injuries Committee of the Medical Research Council.

Prof. F. G. Young, D.Sc., Ph.D., has been appointed to the University Chair of Biochemistry tenable at University College as from Oct. 1. Since 1942 he has held the Chair of Biochemistry at St. Thomas's Hospital Medical School.

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—E. K. Blackburn, J. W. L. Crosfill (with distinction), J. R. Edge, M. Gordon, C. E. Stuart.

FINAL M.B., CH.B.—*Part II*: *J. M. Benjamin, *R. Goldberg, *Henriette Lackner, Katharine M. D. Bailey, J. G. Benstead, C. R. Berkin, N. H. Birch, Annette M. Brooks, A. S. Carey, D. E. Fletcher, R. L. Gibson, J. R. Groves, D. G. Hardy, Nancy Heron, Lilian Hodgson, C. T. Hough, Patricia Hudson, S. Z. Hulman, J. M. Inglis, B. G. Isaacs, F. D. Lumb, Mary M. Matheson, J. Price, A. I. S. Share, Mary R. Sykes.

* With second-class honours.

UNIVERSITY OF LIVERPOOL

Mr. Charles Alexander Wells, M.B., F.R.C.S., has been appointed to the Chair of Surgery and Mr. Thomas Norman Arthur Jeffcoate, M.D., F.R.C.O.G., F.R.C.S.Ed., to the Chair of Obstetrics and Gynaecology in the University of Liverpool. Prof. Wells was lecturer in practical surgery and clinical lecturer and Prof. Jeffcoate gynaecological tutor in the university.

These appointments, the *Manchester Guardian* says, mark a new departure in the history of the Liverpool University Medical School. Hitherto the professors of clinical subjects in that school have been consultants whose time has been divided between the claims of professional practice, both public and private, and the duties of the chair. The responsibilities, however, falling upon the clinical professors in the Medical School have grown considerably in recent years, and it has been thought desirable in the interests of both medical teaching and research to modify the conditions of appointment in the case of the two chairs now filled, and to require their occupants to give whole-time service to the duties of the chairs. Arrangements have been made with the Liverpool Maternity Hospital and the Women's Hospital for the professor of obstetrics and gynaecology to have beds at his disposal in those hospitals, and it is expected that the professor of surgery will have beds in the Royal Liverpool United Hospital.

UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examinations indicated:
